British Pharmaceutical Codex 1959

Pp. xxix+1301. (London: The Pharmaceutical Press, 1959.) 70s.

"THE British Pharmacopoeia" is mainly used by pharmacists. "The British Pharmaceutical Codex" is of more interest to the doctor; it tells him all he needs to know about the official drugs and their preparations, and adds a useful and authoritative summary of their actions and uses. It also gives specifications for other drugs, both old and new. The new "Codex" contains seventy new general monographs mainly dealing with drugs introduced in the past five years, and about one hundred of the old general monographs have been deleted, so that the new edition is shorter than its predecessor, which was itself shorter than the 1949 edition. This shrinkage is due to the elimination of remedies no longer used. The leech was fully described in the 1954 edition with an account of its actions and uses, and recommendations for storage; that monograph has now been eliminated, and the "Codex" has become less picturesque than it was and more like "The British Pharmacopoeia"; the time will probably come when these two standard works will be amalgamated.

J. H. GADDUM

Food Poisoning, Food-borne Infection and Intoxication

Nature, History, and Causation; Measures for Prevention and Control. By Elliot B. Dewberry. Fourth edition. Pp. xvi+411+40 plates. (London: Leonard Hill (Books), Ltd., 1959.) 45s. net.

IT is a platitude to say that everything we eat is perishable, and it is therefore very difficult to understand why until relatively recently a large proportion of those entering the laboratories of the food industry were trained only in chemistry. Of these, some near enough to large industrial areas were able to attend classes in general bacteriology, a

subject very difficult to teach except to full-time students. The remainder were forced to obtain their knowledge solely from text-books. The establishment of courses in food technology at various technical colleges has eased the situation, but the facilities are not yet adequate for the requirements of a virile industry.

First produced in 1943 at a time when the industry was desperately short of laboratory staff, Dewberry's book was a most useful source of information to those dealing with war-time problems of food handling and processing. The third edition in 1950 was still produced "in complete conformity with the authorized economy standards". The present edition, expanded by some 100 pages to include chapters on food hygiene, canned foods and their inspection, and (briefly) *Ol. welchii* food-poisoning, has changed little in quality of production. It has therefore become somewhat bulky for general use.

Although bacterial food-poisoning takes pride of place, sections are included on poisoning by metals, plants, fungi, fish and shellfish and on food allergy. For additional or confirmatory reading there are many references, making the book a most useful source of information for the food technologist and the seriously minded executive. It is, in fact, good value for money.

F. H. BANFIELD

Organic Reactions

Vol. 10. Edited by Roger Adams, A. H. Blatt, V. Boekelheide, Arthur C. Cope, David Y. Curtin, Frank C. McGrew and Carl Niemann. Pp. vii+563. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 96s. net.

THIS volume contains a treatment in the usual detail of three reactions capable of wide application in organic chemistry. The first, dealt with by S. M. Parmerter, concerns the coupling of diazonium salts with aliphatic carbon atoms. An explanation of its character is followed by discussions of its mechanism, scope and limitations, and synthetic applications; the experimental conditions and procedures are then considered; and lastly there is a tabular survey, classified in twelve sections, of the kinds of reactions in question. The treatment is limited to reactions in which the two nitrogen atoms of the diazonium salt remain in the new molecule.

The related Japp-Klingemann reaction is surveyed on similar lines by R. R. Phillips. The treatment of the third member of the triad, the celebrated Michael reaction, occupies the greater portion of the book (pp. 179-555) and affords a contribution of outstanding value: the thoroughness of this co-operative study by E. D. Bergmann, D. Ginsburg and R. Pappo, which was begun at the Weizmann Institute of Science, Rehovoth, is indicated by the accompanying list of 1,045 literature references.

At the end of this volume there are an author index and a chapter (subject) index covering Volumes 1-10 of this invaluable series.

JOHN READ

Reports on the Progress of Applied Chemistry

Vol. 42, 1957. Pp. 910. (London: Society of Chemical Industry, 1958.) 100s.

THIS very valuable review has grown appreciably in size and price. The separate articles are all concisely written, and it would be difficult to say where, if at all, any limitation could be attempted. The book will mostly be of interest to industrial

concerns or research organizations, where price is not important. It contains summaries of a very large field of literature, much of which will be found only in large and specialized libraries, and maintains its high standard, the articles being by experts.

Fundamentals of Physical Chemistry

By Prof. H. D. Crockford and Prof. Samuel B. Knight. Pp. xvii+463. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 56s. net.

THIS book is based on an earlier one intended for pre-medical and other students with a limited knowledge of mathematics. It continues this plan, although the treatment is enlarged by additional topics, including three chapters on thermodynamics. The equations are deduced so far as possible, and special emphasis is given to units. Each chapter begins with a brief statement of its contents, and sub-headings and sections are titled, so that the reader knows just what is being discussed. Fully worked problems are given in the text and review questions and problems at the end of each chapter. Answers to problems are given. The treatment, especially in the part on electrolytes, is modern. The subjects covered are well selected, and the text is concise, carefully written, and clear, the authors having obviously taken great trouble with it. In future editions the conventions of sign of electrode potentials will doubtless be revised in accordance with recent recommendations, which will make the subject much clearer.

This is an excellent introductory book on physical chemistry which can be recommended to those teaching and learning the subject at this stage.

The Chemical Elements

By Helen Miles Davis. Second edition, revised. Pp. viii+198. (Washington, D.C.: Science Service, Inc.; New York: Ballantine Books, Inc., 1959.) 50 cents.

THIS is a very unusual and interesting little book. It was written by Helen Miles Davis, who died in 1957 when the second edition was in preparation. The revision was completed by Dr. Seaborg, the authority on transuranium elements. There is a survey of each element, including the history of its discovery, the whole based on the Periodic Table, and each group has a table of the atomic structure of the elements contained in it. Much of the information is in the actual words of the discoverers, taken from original papers, and this makes the book particularly interesting. The sources, isotopes and properties of each element are given concisely and some characteristic compounds are mentioned. There is nothing superfluous in the book, and its contents are of high standard.

Chemistry for Engineers

An Introductory Course. By Edward Cartmell. Pp. vii+172. (London: Butterworths Scientific Publications, 1959.) 25s.

THIS small book deals with a number of topics of interest to students of engineering which do not usually find a place in the ordinary elementary courses provided for science students. Even if engineering students attend such courses the book will provide a

useful supplement to them. Previous knowledge is limited to such as would be available in schools, and the treatment is restricted to a selection of the more important applications of chemistry of interest to engineers. It includes such topics as fuels, metals and corrosion, water treatment, lubrication and nuclear power. The amount of space devoted to atomic and molecular structure and of valency bonds is rather large, but the treatment is intelligible and interesting. There is a good balance between general theory and practical applications, and the book should be very useful to lecturers called on to cater for the requirements of engineers who have only a limited time to devote to chemistry.

J. R. PARTINGTON

Water Treatment Handbook

Compiled by R. Leviel. Second English edition, revised. Pp. 561. (Suresnes (Seine): Degremont Aefi S.A., 1960. Distributed by Hugh K. Elliott, Ltd., 199 Piccadilly, London, W.1.) 60s. net; 8.40 dollars.

THE first English edition of this book was published in 1955, and there have been four French editions since 1950. After a section on methods of analysis of water and of materials used in water-works practice, the bulk of the work deals systematically and in considerable detail with the various processes used in treating water for domestic and industrial supply. The author is the technical manager of a French company which supplies water-works equipment, and many of the numerous photographs and diagrams refer to the products marketed by the firm. Thus, although methods of treating water do not differ widely in different countries, the present account is of particular value in describing the methods used in France.

Since the last edition, a new and useful section has been added on French legislation governing water supplies and the discharge to streams of sewage and industrial wastes, and containing also the recently published "International Standards for Drinking Water" put forward by the World Health Organization in 1958. There is a substantial section, more than 100 pages in length, of formulae, tables of constants, and the like, which are used in the design of distribution networks and in the treatment of water by physical and chemical methods. There is also a chapter on the treatment of sewage and industrial wastes, but the standard of this, both as regards material and translation, is much below that of the rest of the book.

Atmospheric Diffusion and Air Pollution

Proceedings of a Symposium held at Oxford, August 24-29, 1958. Edited by F. N. Frenkiel and P. A. Sheppard. (Advances in Geophysics, Vol. 6.) Pp. xvii+471. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 12 dollars.

IN order to bring together scientists from the various fields in which atmospheric diffusion is important, an international symposium was arranged jointly by the International Union of Theoretical and Applied Mechanics and the International Union of Geodesy and Geophysics. The symposium was held at Oxford in August 1958, with Dr. F. N. Frenkiel and Prof. P. A. Sheppard as joint secretaries. Seven

sessions dealt respectively with: (1) a general survey; (2) recent findings on atmospheric turbulence; (3) theory of turbulent diffusion; (4) diffusion of heavy or finite particles; (5) transfer through the troposphere and stratosphere; (6) effects of thermal stratification; (7) pollution patterns from point and area sources. Altogether more than forty papers dealing with different facets of the diffusion problem, and presenting the views of authors with different interests, were discussed. These papers, with notes of the ensuing discussions, are brought together in this volume; a few papers which are published elsewhere are represented by extended summaries.

This collection shows how the balance of contributions has, in recent years, swung from the experimental physicist to the theoretician. Possibly this reflects the wealth of empirical data now available. A notable feature is the increasing emphasis on the spectrum of turbulence.

This volume differs from others in the same series which contain articles summarizing selected topics. It is a collection of new results and new ideas which should do much to stimulate scientists who are interested in diffusion. The production is excellent and the editors should feel well satisfied with this final product of their labours.

A. C. BEST

Australian Atomic Energy Symposium, 1958

Proceedings of a Symposium on the Peaceful Uses of Atomic Energy in Australia, held in Sydney from June 2 to 6, 1958. Pp. xi+788. (Melbourne: Melbourne University Press; London: Cambridge University Press, 1960. Published on behalf of the Australian Atomic Energy Commission.) 100s. net.

AUSTRALIAN interest in the scientific and technological aspects of atomic energy was demonstrated in a symposium held in Sydney in June, 1958, under the auspices of the Australian Atomic Energy Commission. The full report of this symposium, containing 114 papers together with discussions, is now available in book form. The scope of the symposium was all-embracing and ranges from the geology of Australian uranium ores and the extraction of uranium from them, the prospects for nuclear power, descriptions of *Hifar*, the 10-MW. heavy-water-moderated research reactor of the Australian Atomic Energy Commission at Lucas Heights, cosmic radiation, the use of radioisotopes in physical and biological research, to education and controlled thermonuclear reactions.

Some of the papers were presented by overseas visitors, and these were generally of a review nature, but most were from Australian sources, the Australian Atomic Energy Commission itself, the Commonwealth Scientific and Industrial Research Organization and other Commonwealth and State Departments, universities, medical schools and industry. Some papers were of a topical nature, others described original work. The general impression is that of work of high quality and of a lively interest.

The volume contains such a wide variety of papers that it is fated to become a library reference book, but there can be no doubt that the symposium which it reports was a very successful affair. Not only did it bring together the wide range of Australian interests in the peaceful uses of atomic energy, but also it stimulated public interest, as was one of its intentions.

A. S. WHITE

Classical Dynamics

By R. H. Atkin. Pp. ix+273. (London: William Heinemann, Ltd., 1959.) 30s. net.

WITHIN the limits imposed by the author he has produced a useful book. The concise explanations are good even though at times the reader may be dissatisfied with them and wish to learn more; this is especially true of the chapter on small oscillations. Moreover, the large number of worked examples and problems should be of value to students and teacher alike.

In the preface the author, who is now principal of Unischol Tutorial College, says: "I have written this book in the belief that it is possible to learn dynamics and answer examination questions at the same time", and later "It therefore seems sensible to present the subject by first explaining the ideas which are involved, in a suitable algebraic framework, and then illustrating the scope of their applications by solving a large number of typical problems". It is written for physicists and covers most of the classical dynamics in two and three dimensions needed by undergraduates up to, but not including, a reference to Hamilton's equations and variational methods.

Thus "Motion in a Plane" (Chapter 5, Section 3) consists of a clear one-page description of the importance of linear momentum, angular momentum and energy, and of the equations which contain them, together with five well-known examples which between them illustrate problems in trajectories, two particles, the use of conservation laws and rotating axes.

A book of this type is not a text-book but a manual, and the publishers admit this on the cover. No attempt is made to describe the principles of mechanics or to explain how these principles are used in the construction of apparatus and the description of physical phenomena. There is no suggestion that there are difficulties in understanding, for example, angular momentum and gyroscopic motion and that these difficulties have caused scientists to write monographs on these matters. So far as I can discover, modern physics is not even mentioned. In short it in no way resembles my idea of a good text-book on mechanics, either for a mathematician or for an engineer or a physicist.

I think it is fair to ask whether there is any need nowadays for text-books on dynamics except for engineers and for examinations. Since the excellent books by Lamb many more have been published, but few, if any, of them are better. Mechanics is only one of the branches of physics from which admirable problems can be drawn to illustrate the use of the differential and integral calculus. The idea that mechanics and applied mathematics are one and the same thing is Edwardian and can now be quietly forgotten.

G. J. KYNCH

Optics

By Dr. C. J. Smith (A Degree Physics, Part 3.) Pp. vii+736. (London: Edward Arnold (Publishers), Ltd., 1960.) 63s. net.

THIS volume continues Dr. Smith's series of books designed for students taking the B.Sc. General degree. The early chapters deal with the general properties of waves and vibrations, with the measurement of the velocity of light, and with the wave-theory and Newton's corpuscular theory. Lenses

are followed by a detailed treatment of non-paraxial rays and aberrations, and of the simpler optical instruments. The full and critical discussion of colour and colorimetry and the two chapters on interference in thin films and in thick plates are good and up to date, as chronicles of progress. But it seems strange to find, in a book of this level, accounts of line spectra and photoelectricity that do not mention quanta or photons; a brief mention of the electromagnetic theory in the last chapter so that polarization by reflexion can be explained in terms of the Fresnel equations (quoted); and nearly everything that Michelson is known for except the Michelson-Morley experiment. It is almost as if the book had been censored; in which case a titillating phrase about the special theory of relativity on p. 35 has been missed.

One must of course be reasonable. The author has had to decide where and when in this monumental series he will introduce a given topic, and its very scale must lead to an almost ruthless compartmentalizing and some very difficult decisions. One thing has to be done thoroughly at a time, and the student who has worked through the text of this volume will have gained a very thorough grounding in optics. He should certainly never find himself at sea; so that this compartment really need not have been quite so watertight.

Thermodynamics

By Gordon J. Van Wylen. Pp. xxiii+567. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 64s. net.

PROF. VAN WYLEN'S book is directed to the engineer, and here the comparison would probably be with Roberts and Miller, or with Zemansky. The idea of temperature and the zeroth law of thermodynamics, and the properties of pure substances, are first discussed; entropy is treated as an important and exchangeable physical property of a system; and the concept of irreversibility is thoroughly explored. Practical power and refrigeration cycles, and the operation of turbines, are explained, with many examples. The interesting thing here is the emphasis on general principles and their applications to the real world; the older outlook was perhaps centred on the ideal gas and the reversible cycle and a mathematician's entropy that started as a perfect differential and ended up as the logarithm of a probability. Some of the revered conventional textbook material cannot be found here at all, and some is mentioned only briefly; this has made for a clearer and more attractive presentation of the macroscopic point of view.

G. R. NOAKES

Modern Physics

By Prof. H. A. Wilson. Fourth edition. (The Student's Physics.) Pp. xv+473. (London and Glasgow: Blackie and Son, Ltd., 1959.) 40s. net.

THERE must always be some doubt about the length of time for which a text-book should be kept alive. The first edition of this book was published in 1928, and it was then up to date and authoritative; now it is sadly behind the times. The author is, of course, an authority on the theoretical aspects of the physics he treats, but he does not seem to be

at home in the new sections on semi-conductors (6 pp.), low-temperature physics (11 pp.), and elementary particles (2 pp.). Some of the chapters such as that on X-ray crystallography look old-fashioned, and it is surprising to find a topic such as the *J* phenomenon still included.

The trouble is that a text-book cannot be kept up to date merely by adding sections "here and there" (the phrase used in the dust cover); there must be pruning and re-distribution as well. The author has sadly failed to live up to the title of "Modern Physics".

H. LIPSON

Methods of Experimental Physics

Vol. 1: Classical Methods. Edited by Immanuel Estermann. Pp. xii+596. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.) 12.80 dollars.

THE series of volumes of which this is the first covers the whole field of experimental physics, and the term "Classical Methods" is explained in the preface as meaning the kind of experiment that is associated with the conventional subdivisions of macroscopic physics. It deals with the evaluation of measurements; the definitions of fundamental units and the determination of 'best values' of the fundamental constants; the mechanics of solids, of fluids, and of vibrations; heat and thermodynamics; optics; electricity; and magnetism. The authors, while working as a team and preserving a uniformity of style, have enjoyed considerable latitude in treatment; some, as P. M. Marcus on thermodynamics, have gone fairly deeply into the underlying theory; others, as J. R. Holms and G. L. Weissler on optics, have concentrated on a full discussion of experimental details. The result is a concise summary of modern techniques, which is in many places a good deal more readable than the usual kind of reference book. It is intended for the physicist who needs a concise and critical guide on matters outside his own special field, and should prove useful for this purpose.

G. R. NOAKES

Nuclear Reactor Materials

By Dr. B. R. T. Frost and Dr. W. B. Waldron. (Nuclear Engineering Monographs.) Pp. vii+79. (London: Temple Press, Ltd., 1959.) 12s. 6d. net.

THIS monograph is one of a very useful series dealing with the physics and engineering of nuclear reactors. It is intended for the use of university and technical college students, research assistants and qualified technicians who require a broad understanding of those topics of nuclear engineering outside their own particular field of study. Previous volumes in the series have dealt with basic nuclear physics, reactor theory, heat transfer, shielding, and reactor control and instrumentation. The present volume gives an excellent outline of the special physical and mechanical properties required of the structural and fuel materials used in reactors and of the recent metallurgical developments in order to provide these materials. The monograph is based on a series of lectures which was given by members of the staff of the Metallurgy Division, Atomic Energy Research Establishment, Harwell, to students in the Department of Nuclear Engineering, Queen Mary College, London, and both the authors are members of the staff of the Division.

The contents consist of six chapters and a comprehensive bibliography. In Chapter 1 the more important aspects of modern metallurgical theory are surveyed, and the common metallurgical terms are explained. Chapter 2, devoted to structural materials, deals separately with aluminium, magnesium, beryllium, iron and steel, and the refractory metals, zirconium, niobium, tantalum, vanadium and molybdenum. Subsequent chapters deal with the fuel materials (uranium, plutonium and thorium); liquid metals as coolants and as carriers for liquid-metal fuels and blankets; ceramics and metal-ceramic mixtures used as fuels, moderators, or as control and shielding materials; and the final chapter discusses the problem of corrosion of the fuel and casing materials by the various coolants. The text is adequately supplemented by tabulated data and clear line drawings. S. WEINTROUB

Nuclear Reactor Optimization

By P. H. Margen. (Nuclear Engineering Monographs.) Pp. x + 81. (London: Temple Press, Ltd., 1960.) 12s. 6d. net.

THE book which is under notice is intended to provide students and research assistants with a broad understanding of specific topics in this field. It competently describes a technique, based on fairly elementary formulations of the relevant theory, for varying the parameters of a given power reactor design to reach the lowest overall power cost and gives a detailed discussion of the application of this technique to a heavy-water-moderated, carbon-dioxide-cooled reactor.

Such a discussion requires a brief comment on almost all the factors which affect the design of the reactor, and the author has succeeded in providing a mass of detailed information without obscuring the main lines of the argument.

This presentation may lead the reader to conclude that effective design can therefore always be achieved by appropriate modification of the elementary mathematical procedures described in this book. In practice, validation of a particular design requires the use of markedly more sophisticated computational techniques. These provide a starting point for an optimization study and must again be used to check the optimized design if it departs appreciably from the initial concept.

In fact, a situation in which all main reactor parameters can be fixed merely by a minimization of total power cost is unusual—and the inclusion of constraints such as peak fuel centre temperature or burn-out margin is vital to the analysis. The essential role of such constraints is insufficiently emphasized in the presentation.

These criticisms do not obscure the merits of a clear presentation of an important aspect of reactor design.

J. FELL

University Physics

By Prof. F. C. Champion. Revised, one volume edition. Pp. viii + 786. (London and Glasgow: Blackie and Son, Ltd., 1960.) 30s. net.

THIS book aims at giving what might be called basic physics—roughly the content of first- and second-year university courses—in one volume. It succeeds in this aim by sternly resisting any temptation to stray on to specialized topics, and it thus gives the impres-

sion of being rather dull. There are, however, three chapters at the end that deal with modern physics, but they do not go deeply into any aspects.

Many examples of examination questions, with answers and hints for solutions, are also included. These are not always wisely chosen; often they are purely bookwork questions which do not give the aid to students that quantitative problems would give. Moreover, the practical element sometimes seems to be lacking; in a.c. theory, for example, the emphasis—quite rightly—is on basic principles, but there should also be some attention paid to producing answers in ordinary units.

It might also be mentioned that a Cartesian convention is used for optics, in accordance with general university practice. In electricity and magnetism the c.g.s. system is used, the m.k.s. system being dismissed rather summarily.

To summarize, this is a sound book that will be useful as a reference book for students, but it is unlikely to fire them with an enthusiasm for physics.

H. LIPSON

Analytical and Canonical Formalism in Physics

By Prof. André Mercier. (Series in Physics.) Pp. viii + 222. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1959.) 40s.

LAGRANGE'S formalization of analytical dynamics by sets of differential operators applied to certain functions characterizing a dynamical system led to Hamilton's variational principle and his canonical equations. The extension of the field of application of Hamilton's principle, from classical dynamics to more general physical systems, may sometimes have seemed to be an exercise in pure mathematics, but relativity and quantum field theory have renewed the interest in structural formalism, so that it is not surprising that one of Prof. Mercier's aims is to show that much of the modern formal field theory is of pre-quantum character. The emphasis is on structure, but here and there illustrations from specific physical domains are given, and a number of problems for the reader are proposed; these are not examination-type questions, but generally ask for the completion or extension of abbreviated detail in the text. The book provides a profound investigation of the role of basic mathematical formalism in physics, from Lagrange to Dirac, and will repay those readers who are prepared to follow a closely argued mathematical essay in anatomy.

T. A. A. BROADBENT

A Course in Applied Mathematics

By Prof. Derek F. Lawden. Pp. xv + 655. (London: English Universities Press, Ltd., 1960.) 70s. net.

PROF. LAWDEN'S book is chiefly intended for students reading for Part 2 of the London General B.Sc. under the recently revised regulations. It conveniently contains all the applied mathematics required by this syllabus: Lagrange's equations, but not variational principles, in dynamics; the elements of the Faraday-Maxwell electromagnetic theory and foundations of potential theory; stress and strain and simple elastic problems; basic equations for the motion of an ideal fluid, with simple instances of irrotational flow and of vortex motion.

The text is clear and logically organized; a knowledge of vector algebra is assumed, but vectors are used sensibly and appropriately, and no attempt is made to force every argument into a vector mould. The operators 'grad', 'div' and 'curl' arise naturally in field theory, though perhaps a little more stress might have been laid on the fact that these are simply three aspects of the single Hamilton operator ∇ . There is a good supply of worked examples and of exercises for the student, carefully selected from degree examinations to illustrate the principles and details of the theory.

This is a very useful text-book, and if it is a little deficient in outlook value, that may be because the author has chosen to work thoroughly in a carefully restricted domain.

T. A. A. BROADBENT

How Photography Works

By Dr. H. J. Walls. Pp. 352. (London and New York: Focal Press, Ltd., 1959.) 42s. net.

THIS book can be strongly recommended to those making a career in the profession of photography who have already acquired some photographic knowledge. Despite some good attempts by the author to justify his claim in the preface that no scientific knowledge is assumed, it must be stated that the book would prove difficult reading for any person without a good knowledge of general science at Intermediate examination level. While not being a text-book, it would be excellent general reading for such people and, for this reason, it should also appeal to amateur photographers having a similar educational background.

After the first chapter on the formation of an image, which includes many features of lens design, there follow nine chapters on the mechanisms of the photographic process from initial exposure to the completion of processing. Two chapters deal with the subjective aspects of viewing photographs and there are also two chapters on colour photography. After each chapter good references are given for further reading, and the index has been carefully prepared.

R. B. COLLINS

Handbook of Textile Fibres

By Dr. J. Gordon Cook. Pp. xxv + 422. (Watford: Merrow Publishing Co., Ltd., 1959.) 15s. net.

THIS book well justifies its title. It is most handy for looking up things about textile fibres in use to-day, of every kind apparently, natural and man-made, that one can think of. They comprise natural fibres, vegetable, animal and mineral; regenerated fibres of polysaccharide and protein origin; and synthetic fibres from polyamides, polyesters, polyvinyl derivatives, polyolefines, glass, ceramics, metals—there are, in fact, almost four double-column pages of them in the index. That does not mean, though, that the book is stodgy and chiefly masses of tables—far from it: also presented are the history and economics, production and processing (with special attention to dyeing), structure and properties, the behaviour of the fibre in practical use, and technical notes besides; all set out compactly and systematically yet achieving the double purpose of a reference book for the more experienced technologist and of an instructive general guide for the beginner. It is comprehensive enough as an introduction to textile fibres

as a whole, and also provides comprehensive details about them as individuals. It could scarcely be more useful for its size, and is strongly recommended.

W. T. ASTBURY

Siberian Arctic

The Story of the Siberia Company. By Jonas Lied. Pp. 214 + 31 plates. (London: Methuen and Co., Ltd., 1960.) 30s. net.

THE events described in the main part of Mr. Lied's book took place during 1910–1920, though they are prefaced by an admirable *résumé* of the previous history of Siberia and followed by an account of what is known of events under Soviet rule.

In 1910 the only practical transport routes from the vast Siberian plains were along the course of the Rivers Obi and Yenisey; the Obi and its tributaries navigable for some 9,000 miles, and the Yenisey for 2,000. To the south the rivers met the Trans-Siberia Railway, a means of transport to the west, but a prohibitively expensive one for trade purposes; and to the north they flowed into the Kara Sea, a potential cheap waterway to the markets of Europe and America. The possibilities of this route had interested various merchant adventurers, but, until 1910, none of them had possessed the necessary business ability and resources to develop them. Then Alfred Derry, buyer and director of Messrs. Derry and Toms, drapers of Kensington High Street, London, caught a glimpse of the vision during visits to the annual trade fair at Nijny Novgorod. A chance meeting with an energetic young Norwegian, Jonas Lied, followed, and early in 1912 was formed the Siberian Steamship Manufacturing and Trading Co. Ltd. Lied himself carried out all the investigations and negotiations at the Russian end, and his account of those exciting days is the best part of the book. The first successful season was in 1913 when cargoes of cement and assorted trade goods were exchanged for two camels from Turkestan, two bears, a roebuck and an assortment of more-valuable, if less-colourful, local products. Exports from Siberia included timber, flax, hemp, wheat, hides, butter and potash; imports were machinery, cement and general trade goods. The company, after initial vicissitudes, was advancing towards success when the Russian revolution put an end to its prospects, though it was a long time dying against a somewhat tedious background of internal squabbles.

L. M. FORBES

Geology of Norway

Edited by Olaf Høltedahl. Pp. xii + 540, with 21 separate maps. (Oslo: Norges Geologiske Undersøkelse, No. 208, 1960.) 100 Norwegian crowns.

Geology of Sweden

Description to accompany the Map of the Pre-Quaternary Rocks of Sweden. By N. H. Magnusson and others. Pp. 177, with map (1:1,000,000) in three sheets. (Stockholm: Sveriges Geologiska Undersökning, Ser. Ba, No. 16, 1960.) Text 15 Swedish crowns, map 45 Swedish crowns.

MODERN text-books on the geology of Norway and of Sweden have, until now, been available only in the national languages and in Russian translations; and a most welcome outcome of the twenty-first International Geological Congress in Scandinavia is the appearance of these new works in

English, compiled by the respective Geological Surveys. The text on Norway, by 21 authors, carefully summarizes the extensive literature and is particularly valuable for its well-chosen bibliographies. It is accompanied by an attractively coloured 'solid' map of the country on the scale 1:1,000,000, a 'drift' map (1:2,000,000), and nineteen other maps on various scales illustrative of classical Norwegian districts and of the economic geology. The memoir on Sweden is the work of five authors and, like the maps, relates to the solid geology only; but a comparable monograph by G. Lundqvist on the Quaternary formations (Stockholm: Sveriges Geologiska Undersökning, Ser. Ba, No. 17, 1960), with drift maps, has been published separately at the same price. All these publications will have a long life and should find a place even in the smaller geological library.

C. F. DAVIDSON

The Early Lectures of Ralph Waldo Emerson

Vol. 1: 1833-1836. Edited by Stephen E. Whicher and Robert E. Spiller. Pp. xxvii + 545. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1959.) 100s. net.

SOON after his resignation from the pastorate of the Unitarian Church at Boston, Emerson considerably extended the cultural activities of the district by a series of lectures for which he has become well known. They were particularly concerned with the elucidation of natural phenomena, the biographies of great men and literature. To each lecture Emerson brought the fruits of keen observation, wide reading and powerful thinking. The result was a many-sided contribution to knowledge and philosophy, which, in this new work, emerges with a freshness which is remarkable for material published one hundred and twenty years ago. Reasons for the study of natural history, man's place in the universe, Emerson's keen analysis of the place of water in Nature; notes on his wanderings in Italy; the life-histories of Luther, Michelangelo Buonarroti, Mellor, George Fox, Burke; an account of the traits of the "English National Genius", all reveal Emerson as a man whose contributions to cultural life were deep and wide-ranging.

Profs. Whicher and Spiller have worked long and patiently to produce the lectures in a form complete with extensive technical and informative notes which make them invaluable for reading material originally intended for oral communication.

Subject Catalogues

Headings and Structure. Pp. 186. (London: The Library Association, 1960.) 22s.; 3.30 dollars.

IN this book Mr. Coates, who has been in charge of the cataloguing side of the "British National Bibliography" almost from its inception, deals with some of the problems which arise when an attempt is made to build subject catalogues, classified or alphabetical, on some systematic basis. It is concerned essentially with first principles, but assumes some background knowledge such as can be acquired from a standard text-book on cataloguing, and it not only directs attention to the shortcomings of some of the classification schemes in general use but also provides a timely warning against excessive reliance on mechanical information retrieval, and a reminder that a machine cannot produce more than has origin-

ally been put into its construction. After describing C. A. Catto's contribution to the systematization of alphabetical subject indexing, Mr. Coates reviews the subsequent contributions to subject-heading theory of Keiser, Ranganathan and Faradane. Then, after a chapter on the dictionary catalogue since Cutler, he examines the contribution of classification and outlines the application of Ranganathan's chain procedure to the colon classification and to the decimal classification. Finally, after considering the use of group arrangement in the subject index, Mr. Coates discusses the subject catalogue from the point of view of the user. Comprehensive references to the literature enhance the value of a scholarly book not merely to practising cataloguers and to students of cataloguing but also to those concerned with the further research in classification which is still required.

Britain's Scientific and Technological Manpower

By George Louis Payne. (Prepared for the President's Committee on Scientists and Engineers.) Pp. xiii + 466. (Stanford, Calif.: Stanford University Press; London: Oxford University Press, 1960.) 45s. net.

THIS book is based on a review of British official documents dealing with technological man-power undertaken at the request of President Eisenhower's Committee on Scientists and Engineers. Essentially it is an expansion of an annotated bibliography of official documents and publications concerning British scientific and technological man-power and education, and this literature is covered comprehensively up to the time of Lord Hailsham's appointment as Minister for Science. With the exception of the Crowther Report and the second White Paper on Industrial Research and Development Expenditure, 1958, there is very little of importance that is not covered, and the value of the survey both to the American and to the British reader is enhanced by the effort made to present where possible comparable American statistics.

The scope of the survey and the broad view taken are sufficiently indicated by the chapter headings. Introductory notes on terminology, etc., and a chapter on the problem and its background are followed by chapters on technical man-power and its employment in 1956 and on current and expected demand for scientists and engineers. Three chapters follow on the secondary schools, the universities and on non-university channels to a technical education. Next come two chapters on the expansion of educational facilities and on the expansion of educational opportunities, the latter dealing with scholarships, student release by employers and the like; and finally two chapters on research and development and on technological expansion and the social scene. There are some supplementary notes on professional terms and institutions and on the universities in an appendix, and also some notes on American man-power statistics.

What critical comment the book contains is mainly in the last chapter; but the value of the book lies in its comprehensive presentation of published information on the scientific and technological man-power situation in Great Britain since the Second World War in all its varied aspects. It is an admirable reference work, and British as well as American readers should be grateful for the thoroughness with which the information has been collected and the clarity of its presentation.

a consistent direction of magnetization up to 4° away from the magnetizing field direction. This natural anisotropy precludes the use of separate specimens for non-pressure and pressure experiments.

This factor, together with the grain-size factor, may have contributed to the experimental results which led Stott and Stacey to suggest that the effect of pressure on a rock acquiring a thermoremanent moment was completely reversible.

It is hoped to publish in the near future a fuller description of the experiments and results of this investigation, which has been carried out with the supervision and encouragement of Prof. J. M. Bruckshaw.

METEOROLOGY

Autumn Temperatures in the Red Sea Hills

DURING the autumn vacation, we made geomorphological and biological surveys in the Red Sea hills and coastal plain north of Port Sudan. Details of these will be published later. While trekking among uncharted jebels in the area 36.50° E., 21.00° N., high surface temperatures were recorded, especially on wind-blown sand. For example, on September 24, 1960, at 1300h. local time, when the air temperature varied between 40.5 and 43.5° C. (105 – 110° F.) the surface sand temperature was 83.5° C. (182.5° F.) as measured with an electrical resistance thermometer employing thermistors¹. The only animal to be seen was a solitary grasshopper. Four hours later, when the temperature had fallen to 32.0° C. (90.0° F.), the sand temperature had dropped 45.5° C. to 38.0° C. (100.5° F.) and some ants were crawling over it.

These results give some idea not only of the enormous temperature fluctuations that occur in desert regions^{2,3} but also of the high ground temperatures that are by no means unusual in the Sudan even quite late in the year. They compare with 84° C. (183° F.) recorded on the Loango Coast close to the equator, 78° C. (172° F.) on a sand dune in the Sahara⁴, a black bulb temperature and sand surface temperature of 58° C. (136° F.) near Cairo⁵. Very much higher temperatures were obtained in fine wind-blown sand, which must have high insulating properties, than on mixed or coarse sands, gravel or rock surfaces.

RADIATION CHEMISTRY

Kinetics of Radiation-induced Chemical Reactions

THE development of linear accelerators which can produce electron pulses a few μ sec. long with a peak current of several hundred m.amp. and an energy of several MeV. has made possible the study of chemical reactions by techniques similar to those used in flash photolysis. A single pulse from this type of machine will deliver a dose of the order of several thousand rads to a few ml. of liquid and should in many cases produce a chemical change large enough to be easily detectable by optical absorption with a time resolution as low as 0.1μ sec. Experiments of this kind, in which the production of the benzyl radical from benzyl compounds in organic solutions was investigated, have already been described by McCarthy and MacLachlan¹. I am doing some similar work on various aqueous solutions, and this communication briefly describes my apparatus and some of the preliminary results obtained with it.

Irradiations are carried out at the Linear Accelerator Facility in the Scientific Apparatus Department, Associated Electrical Industries, Ltd., Manchester, which has available a machine producing 2μ sec. pulses of 4-MeV. electrons². The irradiation cell consists of a thin-walled 'Pyrex' tube 20 mm. diameter and 50 mm. long, closed with quartz end-windows. The electron beam enters through the side of this tube, and a beam of light from a high-pressure mercury lamp passes along its axis. The optical system is arranged to focus the transmitted light on to the entrance slit of a monochromator and then on to a photocell. The photocell output passes through an amplifier with a rise time of about 0.1μ sec. and is applied to the vertical deflexion plates of a cathode-ray oscilloscope the horizontal sweep of which is arranged to start a few μ sec. before the electron pulse. In this way traces are obtained showing the time variation in optical absorption of the liquid in the irradiation cell at any chosen wave-length. With the monochromator entrance slit closed a spurious signal is obtained and shows as 'noise' on the oscilloscope screen. This noise lasts for 2μ sec., and is caused by electrical interference produced at the same time as the pulse. Its amplitude is equivalent to a few per cent of the full signal obtained from the light source, and this limits the change in light intensity which can be detected during the pulse to a few per cent. This relatively low level of interference has been achieved by suitable electrical shielding and also by locating the monochromator outside the irradiation area to eliminate gamma-ray effects on the photocell and amplifier. Light is transmitted to the monochromator via an optical system of high aperture with a path-length of about 10 m. Traces obtained with the light source off and the monochromator slit open show an emission of light from the solution caused by the Čerenkov effect. The amplitude of this emission is fairly constant for 2μ sec., and the rise and fall times are a few tenths μ sec. The optical system was designed to reduce the quantity of this light reaching the photocell to a minimum, and in practice the amount received is of the order of 10 per cent of the light from the lamp. The true absorption of a solution during the pulse is found by comparing traces made with the lamp on and off. The effects of Čerenkov light and electrical interference become

negligible a few tenths $\mu\text{sec.}$ after the pulse, and from this time onward it is possible to detect changes in light intensity of about 0.1 per cent. The lamp output stays constant to better than this for periods of several hundred $\mu\text{sec.}$, and changes in its output only become a limiting factor over longer intervals. Fig. 1 illustrates the performance of the apparatus at high sweep speed and high sensitivity. It was taken at 3100 Å. with once-distilled water containing dissolved air and shows an absorption after the pulse which decays with a short time constant, followed by a longer one. During the pulse the spot was deflected off the screen by the signal from the Čerenkov light. The amplitude of this deflexion was smaller with the lamp on, thus showing the presence of absorption during the pulse.

Fig. 1. Optical transmission of water at 3100 Å. ($\Delta\lambda$ 100 Å.) after a 2- $\mu\text{sec.}$ electron pulse

With many solutions, permanent changes in optical absorption are produced by radiation because of the formation of stable products. I have examined the rate at which these changes occur in 5×10^{-3} molar ceric sulphate (in normal sulphuric acid) and also in three different strengths of ferrous ammonium sulphate (in 0.8 normal sulphuric acid containing 10^{-3} molar sodium chloride). Ceric sulphate absorbs light at 3350 Å. and is reduced to the non-absorbing cerous form by radiation. After a single electron-pulse the optical transmission at this wave-length was found to increase with a half-time of approximately 100 $\mu\text{sec.}$ towards a new steady value. Ferrous ammonium sulphate, on the other hand, is transparent in the ultra-violet and is oxidized by radiation to the ferric form which has a broad absorption band with a maximum at 3100 Å. The optical transmission at 3150 Å., after a single electron pulse, was found to decrease towards a new steady value at a rate dependent on the initial concentration of ferrous ion. Fig. 2 shows a trace obtained with a 10^{-3} molar solution. The small dot in the top left-hand corner is the transmission immediately before the pulse and the steady decrease to a nearly constant value of about 85 per cent at 5 msec. is attributed to the production of ferric ion. The sharp transient just after the pulse was also found in sulphuric acid and is

Fig. 2. Optical transmission of ferrous ammonium sulphate solution at 3150 Å. ($\Delta\lambda$ 100 Å.) after a 2- $\mu\text{sec.}$ electron pulse. 10^{-3} molar ferrous solution, 10^{-3} molar sodium chloride, 0.8 normal sulphuric acid

Fig. 3. Rate of appearance of ferric ion in ferrous ammonium sulphate solution after a 2- $\mu\text{sec.}$ electron pulse. D , Optical density at 3150 Å.; D_{∞} , final steady value of density

thus not likely to be directly concerned with the ferrous-ferric reaction. The optical density D of the solution at any time after the pulse should be proportional to the amount of ferric ion present at that time and can be calculated from curves of this type. D approaches exponentially towards a final steady value D_{∞} and in Fig. 3 $D_{\infty} - D$ is plotted as a function of time for three different concentrations of ferrous ion. The slight variation in D_{∞} for the three curves is probably due to the variation of dose among pulses. The half-times ($T_{1/2}$) are inversely proportional to the concentration, and the values obtained indicate that the probability of oxidation of a ferrous ion by a radical is of the order of 10^{-5} per collision. The exponential build-up of ferric ion shown here is perhaps unexpected in view of the complicated mechanism usually postulated for this reaction³. However, my results do not at present exclude components with much longer half-times.

These experiments are being continued, and the kinetics of a variety of radiation-induced chemical reactions will be studied in detail. I wish to thank Associated Electrical Industries and the staff of their Irradiation Facility and also the staff of the Biochemistry Department of the Christie Hospital and Holt Radium Institute for their co-operation in this work.

Reversible Behaviour of the Ultra-violet Irradiated Deoxyribonucleic Acid and its Apurinic Acid

THE present communication reports changes produced by ultra-violet irradiation in thymidylic acid (A), deoxycytidylic acid (B), apurinic acid (C), deoxyribonucleic acid (D) and a 1:1 mixture of A and B, and also the reversibility of these changes in C and D. The conditions of the irradiation are described in a previous paper¹. Apurinic acid was prepared according to the method of Tamm, Hoder

Table 1

Optical density decrease (min.)	A	B	A + B	C	D	2 × D
0-5	0.034	0.071	0.058	0.235	0.097	0.194
5-10	0.024	0.035	0.023	0.079	0.049	0.098
10-15	0.008	0.019	0.011	0.050	0.022	0.044
15-20	0.008	0.006	0.017	0.024	0.014	0.028
Total decrease	0.083	0.131	0.109	0.388	0.182	0.364

and Chargaff². The concentration of the solutions was such that at pH 7 (phosphate buffer) the optical density readings at the maxima were 1.000 ± 2 per cent. The irradiation time was 20 min. for each solution, and the decrease of optical density at 260 m μ was recorded at 5 min. intervals, as shown in Table 1.

These results indicate that the decrease in optical density of the mixture of the two nucleotides (thymidylic and deoxycytidylic acids) is approximately equal to half the sum of the two nucleotides irradiated individually ($\frac{1}{2}$ thymidylic acid + $\frac{1}{2}$ deoxycytidylic acid). However, when these two acids together exist in polymeric form, that is, apurinic acid, the decrease in optical density is more than three times that of the monomeric mixture, apurinic acid > 3 (thymidylic plus deoxycytidylic acids). I suggest that this discrepancy may be due to the unique photochemical behaviour of thymine

Fig. 1. Irradiation and reconstitution of apurinic acid. ○, Heated before irradiation (standard); ●, before irradiation (standard); ×, heated (6 hr.) after irradiation; △, standing (8 hr.) after irradiation; □, 20 min. irradiation

Fig. 2. Irradiation and reconstitution of deoxyribonucleic acid. ○, Heated before irradiation (standard); ●, before irradiation (standard); ×, heated (135 min.) after irradiation; △, standing (180 min.) after irradiation; □, 20 min. irradiation

derivatives³. Thus, I have pointed out that in polymeric nucleic acid, an unstable and reversible intermediate, 6-hydroxyhydrothymine derivative, could be formed and thus given an apparent decrease in optical density at 260 m μ . In the monomeric form (that is, thymidylic acid), the unstable intermediate would revert to the starting material during irradiation, while the slow decrease of optical density at 260 m μ would result only from degradation of this intermediate. If the above assumption is correct, the decrease of optical density of the polymer is therefore entirely owing to the irradiation effect on the two pyrimidine bases. Since purine bases are unaffected under these irradiation conditions⁴, the decrease of optical density for deoxyribonucleic acid, containing about 50 per cent purines, should be half that for apurinic acid. Therefore, if the observed decrease for deoxyribonucleic acid is doubled it should equal that of apurinic acid, which is a purine-free pyrimidine nucleotide polymer. The experimental data support this hypothesis⁵.

The reversibility of irradiated deoxyribonucleic acid and apurinic acid as indicated by ultra-violet spectra was observed by treatment with heat (70°), acid (pH ~ 2) or acid and heat and also by standing at room temperature. The spontaneous reconstitution is probably due to the reverse isomerization of irradiated deoxycytidylic acid units to the original⁶. The acid or heat reconstitution probably results from

CHEMISTRY

Acidic Dissociation Constants of Alcoholic Hydroxyls of Hydroxycarboxylic Acids: Tartaric Acid

dehydration of 6-hydroxyhydrothymidylidic acid units². The increase in optical density in the spontaneous reconstitution of deoxyribonucleic acid reached 0.005 as its maximum value on standing about 3 hr. For heat reconstitution, the value reached 0.092. When compared with the standard curve (heat before irradiation), the portion that is reconstituted is about 50 per cent. In the case of apurinic acid spontaneous reconstitution reached 0.118 in 8 hr. and heat reconstitution reached 0.240 (ref. 7). This is about 60 per cent reconstitution. In acid or acid and heat reconstitution the values were somewhat lower and the absorption maximum shifted to 262 m μ in both cases.

The irradiation conditions that I used were based on our findings in cytosine derivatives. In deoxyribonucleic acid, the cytosine derivative is deoxycytidylidic acid and on irradiation the spontaneously reversible step for the concentration used was completed in about 20 min. This irradiation time was chosen as a standard because it was observed that at the end of 20 min. irradiation time the ultra-violet spectrum started to deviate from the isosbestic point—the criterion for the first reversible step⁴. The total energy input, or number of Einsteins absorbed in solution, was 1.88×10^{-5} Ein./c.c. in a 20 min. period⁸.

Experiments are being continued in the hope that future work will shed some light on the biological aspects of the problem.

R. Beukers, J. Ijlststra and W. Berends⁹ have just published their findings on the ultra-violet irradiation of deoxyribonucleic acid. These findings were based on their previous observations¹⁰ on the irradiation of thymine in the frozen state. I would like to report that the irradiation of thymine and 1,3-dimethylthymine in the frozen state resulted in the formation of dimers. These dimers, determined by elementary analyses, molecular weight, ultra-violet spectra and infra-red spectra, were stable in acid, base and heat. However, in solution they would revert to the original compound when irradiated with 2537 Å. light, but are stable with 3600 Å. or light of longer wave-length. The identification of these dimeric products is being pursued in this Laboratory.

I am grateful to M. Mouyos for technical assistance.

The hydroxycarboxylic acids form very stable complexes with metal ions. In alkaline solution, both the carboxylic and the alcoholic hydroxyl groups take part in complex formation. For the calculation of stability constants of complexes it is necessary to know the acidic dissociation constants of both groups. Since the alcoholic hydroxyls are very weakly acidic and the molecule contains relatively easily dissociable group(s) also, it is not possible to determine the dissociation constants by the usual methods. For mandelic acid the value of the dissociation constant of alcoholic hydroxyl can be calculated from the change of absorbancy at 244 m μ produced by sodium hydroxide¹. However, in general the hydroxycarboxylic acids do not absorb even in far ultra-violet. The acidic dissociation constants of optically active substances may be estimated from the change of rotatory power produced by alkali hydroxide. The present communication deals with tartaric acid.

The rotatory power of tartaric acid first increases with increasing pH and reaches a limiting value about pH 7 (ref. 2). This increase can be attributed to the gradual ionization of the carboxylic groups. Above pH 13 the rotatory power decreases on further increasing the concentration of alkali. Fig. 1 shows the change of the optical rotatory power as a function of pH at Na₂P. We used the pH values determined by Schwarzenbach and Sulzberger³ instead of the concentrations of sodium or potassium hydroxide. It can be seen that in solutions containing sodium hydroxide, the direction of rotation changes at pH 15.76 (7.95 M/litre sodium hydroxide). The rotatory power also decreases in solutions which contain potassium hydroxide, but the direction of rotation does not change. However, at shorter wave-lengths the optical rotatory dispersion curves were determined between 280 and 583.9 m μ —the change of direction of rotation also takes place in the presence of potassium hydroxide. For example, at 300 m μ the rotation is zero in 9.2 M potassium hydroxide (pH 16.9) or in 4.9 M sodium hydroxide (pH 15.1).

Fig. 1. Rotatory power of tartaric acid as fraction of pH. 1, solutions alkalinized by KOH; 2, solutions alkalinized by NaOH.

The main reason for the decrease of rotatory power produced by increase of concentration of alkali is the gradual ionization of alcoholic hydroxyls. The differences accompanying the use of potassium hydroxide and sodium hydroxide for alkalization can be attributed to (i) secondary equilibria, and (ii) the different deformability of sodium and potassium ions. These latter effects were not taken into consideration in making the calculation. The acidic dissociation constants were estimated by Stearn and Wheland's method⁴ modified by us. The acidic dissociation constants were defined by the following expressions:

$$K_3 = \frac{[TH^{3-}][H^+]}{[TH_2^{2-}]}; K_4 = \frac{[T^{4-}][H^+]}{[TH^{3-}]}$$

Using these expressions, we find that the dissociation constants determined in solution treated with potassium hydroxide are $K_3 = 1.13 \times 10^{-14}$ and $K_4 = 2.54 \times 10^{-16}$; for solutions treated with sodium hydroxide, $K_3 = 1.46 \times 10^{-14}$ and $K_4 = 3.23 \times 10^{-16}$.

Details of the experimental work and the method of calculation will be published in *Acta Chim. Hung.*

Theoretical Basis for Kinetic Effects in Gas-Solid Chromatography

LATERAL diffusion in the gas phase as well as sorption-desorption kinetics may both influence the plate height of gas-solid chromatography. While the complicated nature and alignment of adsorbing surfaces in a column cannot be fully described mathematically, a model is presented here which allows for the fundamental diffusion and reaction processes of gas-solid chromatography. The theory is written in a general form which can be readily extended to more complex phenomena. The adsorption isotherm is assumed linear, a condition recently made practical by highly sensitive detectors.

The fundamental equation for non-equilibrium (kinetic) effects in chromatography is¹⁻³:

$$s_i = (v_i - \bar{u}) \partial m_i^* / \partial z \quad (1)$$

where s_i is the rate of accumulation due to kinetic effects of solute in the i th form, v_i is the downstream velocity in the i th form, $\bar{u}$ is the average zone velocity, m_i^* is the equilibrium concentration expressed in the appropriate units, and z is the distance. If $i = 1$ represents the gas (fluid) phase, then we may write²:

$$s_1 = m_1^* D_1 \nabla^2 \epsilon_1 \quad (2)$$

where D_1 is the diffusion coefficient of solute in the gas and ϵ_1 is the equilibrium departure term for the gas. The surface, $i = 2$, accumulates solute on a unit area at the rate³, $s_2 = -k_{21} m_2^* [\epsilon_2 - (\epsilon_2)_{\text{interface}}]$,

where k_{21} is the first-order rate constant for desorption from the surface. If the sorption-desorption kinetics are very rapid, the term in square brackets equals zero, and the equality $\epsilon_2 = (\epsilon_2)_{\text{interface}}$, representing interfacial equilibrium, is a boundary condition³ on ϵ_1 . In this well-known case, diffusion, only, controls the non-equilibrium. In the general case, however, the above equation for s_2 becomes a boundary condition on ϵ_1 . Using equation (1) in which $v_2 = 0$ (because the surface is stationary), this condition becomes:

$$-Rv \partial \ln c / \partial z = -k_{21} [\epsilon_2 - (\epsilon_2)_{\text{interface}}] \quad (3)$$

where v is the average gas velocity, R is the ratio $\bar{u}/v$, and c is the total amount of solute in a unit volume of the chromatogram. The latter may be represented by $c = m_1^* A_1 + m_2^* S_2$, where m_1^* is the equilibrium concentration of solute in the gas, A_1 is the fractional volume of gas, m_2^* is the equilibrium amount of solute per unit area of surface, and S_2 the surface area in a unit volume. The value of R in terms of these quantities is $R = c_1^* / (c_1^* + c_2^*) = m_1^* A_1 / (m_1^* A_1 + m_2^* S_2)$.

If more than one surface is involved (such as with mixed adsorbents or adsorption at a gas-liquid interface), additional surface elements, S_i , must be introduced and treated in an equivalent way. Complications caused by non-uniform surfaces, etc., have been discussed³ in a manner readily applicable to the present case.

The elimination of s_1 between equations (1) and (2) yields the following general differential equation from which ϵ_1 is to be obtained:

$$\nabla^2 \epsilon_1 = \frac{(1-R)v_1}{D_1} \frac{\partial \ln c}{\partial z} \quad (4)$$

A special case is considered here in which parabolic flow occurring between flat plates a distance $2d_1$ apart represents the interstitial flow. The future improvement of this model to represent more accurately the support lattice should permit a significant advance in the theoretical calculation of chromatographic parameters.

Equation (4) is integrated using $v_1 = (3v/2)(1 - x^2/d_1^2)$, where x is the distance from the centre of the channel. Using equation (3) in addition to type 1 and type 5 boundary conditions from reference 3, ϵ_1 is found to be:

$$\epsilon_1 = v \frac{\partial \ln c}{\partial z} \left[-\frac{R(1-R)}{k_{21}} - \frac{x^4}{8D_1 d_1^3} + \frac{x^3}{2D_1} \left(\frac{3}{2} - R \right) - \frac{d_1^3}{120D_1} (40R^2 - 108R + 75) \right] \quad (5)$$

This expression is identical to the one representing ϵ_1 when equilibrium is found at the interface, except that the term containing k_{21} does not appear in the latter. The contribution of the preceding non-equilibrium to the plate height is found in the usual way as:

$$H_0 = \frac{2R(1-R)v}{k_{21}} + \frac{2}{3} \left(R^2 - \frac{12}{5} R + \frac{51}{35} \right) v \frac{d_1^3}{D_1} \quad (6)$$

Each term in this expression has been obtained individually assuming only one process to be rate controlling. The general conditions under which rate effects are additive are, however, not entirely obvious. The fact that they are not always additive has been shown using a specific model for partition chromatography³.

While equation (6) is expected to hold at most velocities, it probably fails at higher velocities. This is the result of the interaction of lateral diffusion in the gas phase with eddy diffusion^{3,4}. The latter involves shuttling molecules back and forth from rapid to slow streamlines, an effect that acts essentially to increase the lateral diffusion coefficient, D_1 . This additional lateral diffusion increases in proportion to flow velocity, and is thus negligible at low velocities.

Equation (6), along with necessary extensions to the present model, should be useful in suggesting ways of changing channel size, temperature, surface area, and other surface properties in a manner that is beneficial to the separability of component zones.

Dipole Moment Data and Hyperconjugation

It is being increasingly recognized¹ that the evidence for hyperconjugation from dipole moment data needs to be re-interpreted. Since the electronegativity of an sp or sp^2 carbon differs from that of an sp^3 carbon, the primary moments of the $C(sp)-C(sp^3)$ and $C(sp^2)-C(sp^3)$ bonds are not zero, and the dipole moments of molecules such as toluene, methylacetylene, etc., may arise solely from this effect.

Recently I have published a method for the calculation of bond moments based on the principle of electronegativity equalization², and I have now applied it to many molecules, including toluene, propylene, and butene-1. In these molecules, the atomic and homopolar dipoles cancel each other and the total moments should be given by the resultant of the vectorial sum of the primary bond moments.

From the data by Pritchard and Skinner³, the electronegativities of sp^3 carbon and sp^2 carbon are 2.63 and 2.88, respectively. Using the screening-constants given by Kohlrusch⁴, we can calculate² the value of the charge transferred in a $C(sp^2)-C(sp^3)$ bond: $q = 0.049$ e.u. Table 1 shows that the calculated primary moments of toluene, propylene, and butene-1, given by the product eqR_0 (column 4), agree extremely well with the experimental values for the dipole moments.

Table 1

Molecule	q (e.u.)	R_0 (Å.)	eqR_0 (D.)	μ_{exp} (D.)
$CH_3-C_2H_5$	0.049	1.52	0.357	0.36 ± 0.02
$CH_3-CH=CH_2$	0.049	1.53	0.359	0.35 ± 0.01
$CH_3-CH_2-CH=CH_2$	0.049	1.54	0.362	$0.38 - 0.30$

Bond distances from "Tables of Interatomic Distances", Special Publication No. 11, Chemical Society (London, 1955).

Dipole moments from Marriott, A. A., and Buckley, F., "Table of Dielectric Constants and Dipole Moments of Substances in the Gaseous State", Nat. Bur. Stand. Circ. No. 537 (Washington, D.C., 1953).

These results can be valid only if the opposed $C(sp^2)-H$ and $C(sp^3)-H$ bond moments are equal. Now, the calculated $C(sp^2)-H$ bond moment in ethylene is 0.40 D., and the calculated $C(sp^3)-H$

bond moment in methane is 0.21 D., but the positive charge in the sp^2 carbon of the molecules under consideration (due to charge transfer to the sp^3 carbon) increases the $C(sp^2)-H$ bond moment considerably; an iterative calculation shows that the two types of $C-H$ bond moments cannot differ by more than 0.05 D.

It seems that the dipole moment evidence for hyperconjugation is not valid, although, since the bond moment is a ground-state property, hyperconjugation may exist in excited states and accordingly be important for the interpretation of the spectra and reactivity of molecules.

A detailed account of this work is to be submitted elsewhere.

Reaction of Aromatic Compounds with a Chlorinated Coal and Aluminium Chloride

VAN KREVELEN *et al.*¹ have reported on the coupling of pitch molecules by chloromethylation and subsequent condensation under the influence of a Friedel-Crafts catalyst, while Iyengar, Banerjee and Banerjee² have claimed the alkylation of coals with benzyl chloride and aluminium chloride. But in these laboratories a similar type of reaction between a chlorinated low-rank coal (containing about 50 per cent of hydrolysable chlorine) and several aromatic compounds, in the presence of aluminium chloride, has given inconclusive results which suggest that alkylation may not have occurred during the reaction with benzyl chloride.

A chlorinated low-rank coal (Ellington High Main 81.0 per cent carbon, 5.1 per cent hydrogen, dry ash-free, N.C.B. Rank Code No. 802), prepared as previously described³, was treated with an aromatic compound (Table 1) under suitable conditions. The dry chlorinated coal (7 gm.) was stirred with 100 ml. carbon tetrachloride (nitrobenzene was used as a solvent in the case of aniline) and 0.5-1.0 gm. of anhydrous aluminium chloride. A blue or green colour developed at this stage, suggesting initial formation of a complex with aluminium chloride. No hydrogen chloride was evolved. The aromatic compound (aniline, toluene, chlorobenzene, dimethyl aniline or dimethylbenzylamine) was then added (2-10 gm.) and the mixture refluxed for about 7 hr. After cooling and filtering, the product was washed with carbon tetrachloride and then dried at 100°C. *in vacuo*.

The results in Tables 1-2 show that, while the changes in elementary composition correspond with the expected reaction, the results do not definitely confirm the alkylation, since there was no corresponding release of hydrogen chloride. The increase in ash content suggests the presence of aluminium compounds in the products. It is doubtful if the results quoted by Iyengar, Banerjee and Banerjee², which do not include ash or chlorine contents,

BIOCHEMISTRY

Biological Dehydroxylation

THE hydroxylation of aromatic compounds in the animal body to form phenols is a well-established biochemical reaction (see review¹) and has been known for nearly a hundred years. It was in 1867 that Schultzen and Naunyn² first showed that benzene was converted to phenol in man and the dog. The reverse reaction, namely, dehydroxylation, is not well known. The first suggestion that such a reaction occurred *in vivo* was published in 1955 when Booth, Murray, DeEds and Jones³ noted an enhancement of the *m*-hydroxyphenylacetic acid output in the urine of rabbits that had been dosed with 3,4-dihydroxyphenylacetic acid (homoprotocatechuic acid) or with the flavonoids, rutin and quercetin. It was suggested that the *m*-hydroxyphenylacetic acid arose by loss of the *para*-hydroxyl group of 3,4-dihydroxyphenylacetic acid. The excretion of increased amounts of *m*-hydroxyphenyl acids has since been observed after the administration of 3,4-dihydroxycinnamic acid (caffeic acid) to man, the rabbit and the rat^{4,5} and after 3,4-dihydroxyphenylalanine (dopa) to the rabbit and the rat⁴. The ingestion of

coffee leads to the excretion of increased amounts of *m*-hydroxyhippuric acid in human urine⁶, and this has been ascribed by Booth *et al.*⁴ to the breakdown of chlorogenic acid, which is the quinic acid ester of caffeic acid, and which occurs in coffee beans to the extent of 5 per cent on a dry weight basis. According to Armstrong *et al.*^{6,7}, *m*-hydroxybenzoic, -phenylacetic, -phenylpropionic and probably -phenyllactic acids occur in human urine, but the origin of these *meta*-acids is obscure. However, these acids could arise during metabolism by dehydroxylation of 3,4-dihydroxyphenyl acids (catechol acids). It is thus possible that dehydroxylation is a reaction of considerable metabolic significance.

It should be mentioned also that biological dehydroxylation has been observed in the quinoline series, for 4-hydroxyquinoline-2-carboxylic acid (kynurenic acid) is partly excreted as quinoline-2-carboxylic acid (quinaldic acid) in man and the rat⁸, and 4,8-dihydroxyquinoline-2-carboxylic acid (xanthurenic acid) is excreted as 8-hydroxyquinoline-2-carboxylic acid in the rat⁹, but 4,8-dihydroxyquinoline is not dehydroxylated⁸. However, the hydroxyl group in the 4 position of quinoline is not strictly phenolic, and the mechanism of its dehydroxylation may not be the same as the removal of the phenolic group in the catechol acids.

In order to put the dehydroxylation of the catechol acids on a sound basis we have synthesized [carboxy-¹⁴C] 3,4-dihydroxyphenylacetic acid and administered this compound by mouth to rabbits. The various metabolites of this acid were then determined by isotope dilution and paper chromatographic techniques after acid hydrolysis of the urine. The results are shown in Table 1.

Table 1 shows that in 44 hr. after dosing with the homoprotocatechuic acid labelled with carbon-14 about 85 per cent of the carbon-14 is excreted in the urine, and this can be accounted for as four compounds. The main excretory product is the original acid. However, both *m*- and *p*-hydroxyphenylacetic acids are labelled and so is 4-hydroxy-3-methoxyphenylacetic acid (homovanillic acid). The last acid

Table 1. METABOLITES OF [¹⁴O]3,4-DIHYDROXYPHENYLACETIC ACID (DOSE, 100 NGM./KGM.)

	Percentage of dose* excreted in 44 hr. determined by isotope dilution

Sum of metabolites	84
Radioactivity of urine after 44 hr.	85.5
Radioactivity of urine after 8-9 days	100.3

* Mean value of three animals

is a known metabolite of homoprotocatechuic acid, of dopa⁴, and of 3,4-dihydroxyphenylethylamine (3-hydroxytyramine or dopamine)¹⁰. Its isomer, 3-hydroxy-4-methoxyphenylacetic acid (homo-*iso*-vanillic acid), was looked for in our experiments but it was not found.

Now the isotope dilutions in our experiments were carried out on ether extracts of the acid-hydrolysed urines, and it might be argued that the *m*-hydroxyphenylacetic acid was an artefact. However, the *m*-acid was found in unhydrolysed urines by paper chromatography in non-acidic solvents and by isotope dilution. In fact, the amount found in unhydrolysed urines was no different from that found in acid-hydrolysed urines, and it was concluded that *m*-hydroxyphenylacetic acid was a true urinary metabolite of homoprotocatechuic acid.

The formation of *p*-hydroxyphenylacetic acid is interesting because it shows for the first time that the *m*-hydroxyl group of a catechol acid can also be lost *in vivo*. A mechanism for the dehydroxylation of catechol acids has been suggested by one of us¹¹. It is suggested that homoprotocatechuic acid is hydrogenated *in vivo* to 3,4-dihydro-3,4-dihydroxyphenylacetic acid, which could then lose water to yield *m*- or *p*-hydroxyphenylacetic acid or both:

where $R = \text{CH}_2\text{COOH}$. The nature of the R group is important for it would influence how much *m*- and *p*-dehydroxylation occurred. When $R = \text{CH}_2\text{COOH}$, more *p*-dehydroxylation than *m*- is to be expected and this is in accord with the figures in Table 1, where the ratio *m*-acid/*p*-acid is 10, which means that there is ten times as much *para*-dehydroxylation of homoprotocatechuic acid as *meta*- in the rabbit.

Dehydroxylation could also be a metabolic reaction of the catechol amines, adrenaline and noradrenaline. *p*-Dehydroxylation of adrenaline would give the known sympathomimetic agent, phenylephrine (or *meta*-synephrine) base and *m*-dehydroxylation, synephrine base. These two amines could be normal metabolites of the body.

This investigation was supported in part by a research fellowship (to R. R. S.), No. EF-8238, from the National Institute of Allergy and Infectious Diseases, United States Public Health Service, and another (J. G. W.) participated during the tenure of a World Health Organization fellowship.

Note added, August 19. Dr. Sidney Udenfriend (National Heart Institute, Bethesda, Md.) has informed us that he has found synephrine in human urine, and an account of this finding is being prepared for publication. He has also directed our

attention to a communication by himself and his co-workers (see Sjoerdsma *et al.*, *Science*, 130, 225; 1959) on the finding of *m*-tyramine (*m*-hydroxyphenylethylamine) in the urine of humans dosed with the monoamine oxidase inhibitor, 1-phenyl-2-hydrazinopropane (JB-516 or 'Catron'). It is possible that *m*-tyramine is a product of the dehydroxylation of dopamine *in vivo*.

Ultra-Violet Photography of Fluorescent Spots on Chromatograms of Biological Extracts

THE use of ultra-violet light to detect and photograph chromatographed compounds absorbing in the region of 254 mμ is well known¹. In the course of investigating a number of unknown compounds found on chromatograms of plasma extracts, a simple technique was developed for photographing spots which fluoresce in ultra-violet light at 365 mμ. This consists of interposing a Kodak 2A gelatin filter, which absorbs radiant energy below 405 mμ, between the chromatogram and the contact paper ('Kodabromide F5'). The filter is enclosed for protection between 1/16 in. glass plates, bound with tape at the edges. The chromatogram is exposed for approximately 30 sec. to ultra-violet light from a 365-mμ source ('Mineralight' handlamp, Ultraviolet Products, Inc., San Gabriel, Calif.) at a distance of 1 ft. The photograph is then developed in the usual way.

To illustrate the application of the method, Figs. 1a and b show respectively photographs taken at 254 mμ without a filter (absorbing compounds), and at 365 mμ with the filter (fluorescing compounds), of a chromatogram of plasma extracts from three normal subjects and three patients with uraemia. In Fig. 1a it can be seen that the plasma concentration of the ultra-violet-absorbing substances X and Y increases with increasing levels of blood urea nitrogen. In Fig. 1b the increased amounts of the fluorescent substance X in the uraemic patients' plasma, compared with that of the normal subjects, is clearly demonstrated. Further work on the identification of both compounds is at present being undertaken.

The technique described dispenses with the need for a camera, and is now used routinely in this laboratory to supplement the information obtained

Fig. 1. Ultra-violet photographs of a descending chromatogram in *n*-butanol/water (86:14), taken at 254 $m\mu$ (a) and at 360 $m\mu$ with filter (b). N, Plasma extract from normal subjects; U, plasma extract from patients with uraemia; X, Y, unknown compounds. Figures in brackets refer to levels of blood urea nitrogen

from 254- $m\mu$ photographs. It is particularly useful for substances such as 5-hydroxyanthranilic acid, which are not detected by the latter method. For compounds such as X, which fluoresce in ultra-violet light and also absorb, the fluorescent technique is the more sensitive. It should be applicable to all substances in which visible fluorescence is activated at wave-lengths below 405 $m\mu$, and thus provides a general extension of the method described by Smith and Markham³, in which a cellulose nitrate filter cutting off wave-lengths below 320 $m\mu$ is used.

This work was aided by a grant from the U.S. Public Health Service A-254(C7).

Oxidative Activity of a Particulate Fraction from *Rumex Virus Tumour Tissue*

ALTHOUGH the capacity of cytoplasmic particles from plant tissues to oxidize Krebs-cycle intermediates has been clearly demonstrated¹, only one investigation to date has been reported on the oxidative reactions of particulate fractions from plant tissue cultures². Such investigations are of particular interest and importance in that they permit an elucidation of the biochemical differences between normal (callus) and neoplastic plant tissues and between tissue cultures and the parent plant parts. This work is concerned with the oxidative activity of a particulate fraction from virus tumour tissue of Black's original *R₁* strain from *Rumex acetosa* L.

The tissue was grown on medium No. 24 of Burkholder and Nickell³ under the conditions previously described⁴. Approximately 15 gm. of tissue, 4-6 weeks old, was ground in a mortar and pestle with 30 ml. of buffer containing potassium dihydrogen

phosphate, 0.1 *M*; sucrose, 0.5 *M*; dipotassium salt of ethylenediamine tetraacetic acid, 0.01 *M*; pH 7.3. A small quantity of quartz sand was added to aid in grinding. The macerate was strained through cheese-cloth and centrifuged at 500*g* for 10 min. The resultant supernatant was centrifuged at 20,000*g* for 20 min. and the pellet finally obtained was suspended in 3.0 ml. of buffer containing potassium dihydrogen phosphate, 0.02 *M*; sucrose, 0.4 *M* and magnesium chloride, 0.005 *M*, pH 7.2.

All the above operations were carried out at 0-4° C. Manometric measurements were conducted at 30° C. using standard Warburg apparatus. Nitrogen content of the particulate suspensions was determined on 1.0-ml. samples of suspensions which had been diluted 1:10 with distilled water. The samples were digested by a micro-Kjeldahl method and neeslerized. Nitrogen was determined colorimetrically in a Klett-Summerson photoelectric colorimeter equipped with a 490- $m\mu$ filter.

All reagents used were of the highest quality available commercially.

The particulate suspension was yellow in colour, and microscopic examination with an oil-immersion objective showed that it consisted of oval particles which stained with janus green B. These particles were very similar in appearance to particles commonly referred to as mitochondria.

The particulate suspension catalysed the oxidation of citrate, α -ketoglutarate, succinate, fumarate and malate (Table 1). The rate of pyruvate oxidation was very low, but the addition of catalytic amounts of malate resulted in a considerable increase in pyruvate oxidation (Table 2). The use of malate as a 'sparker' in pyruvate oxidation has been previously reported⁵. Of the other Krebs-cycle acids utilized as substrates, succinate was oxidized most rapidly while the rate of fumarate oxidation was repeatedly the lowest obtained. These findings could account for the reported accumulation of fumarate in older tumour tissues⁶.

A cytochrome oxidase system is present in *Rumex* tumour tissue⁶ although the rate of oxidation of all but two of the substrates utilized, citrate and malate, was not significantly enhanced by the addition of cytochrome *c*. The failure of added cytochrome *c* to

* Oxygen uptake in presence of malate (0.001 *M*) showed no measurable increase over endogenous rate.

enhance oxidation has been interpreted as indicating that the mitochondrial complex has been isolated in reasonably intact form, and that sufficient cytochrome *c* is bound to the particles⁷. It is possible that in cases where added cytochrome *c* failed to enhance the rate of oxidation of substrate other factors may be limiting⁸.

Evidence is presented to demonstrate that *Rumex* virus tumour tissue cultivated *in vitro* contains particles which possess the capacity characteristic of plant mitochondria to oxidize Krebs-cycle acids.

The able assistance of Mrs. Eugenie M. Stacey is gratefully acknowledged. This work was supported by a grant (C-4052) from the Public Health Service, National Cancer Institute.

Enzyme Repression as the Control Mechanism in the Synthesis of Induced β -Galactosidase

It is known that the mechanism controlling the level (synthesis) of the constitutive enzymes in cells is enzyme repression¹. An early example for enzyme repression was the inhibition of the synthesis of constitutive β -galactosidase by lactose or galactose². In the present investigation I have examined the regulation of the synthesis of induced β -galactosidase.

The strain *Escherichia coli* ML 30 and the medium M-9 (ref. 3) which contains either 2 mgm./ml. maltose—twice recrystallized from 80 per cent ethanol—or glycerol as sole source of carbon were used in this work. The inducer, isopropyl-thio- β -D-galactoside⁴ or lactose, was added to the exponentially growing culture, containing 30 μ gm./ml. bacterial dry weight, at 37° C. on a rotary shaker. At intervals, during the first one and a half division after the addition of inducer, samples were taken for galactosidase and dry-weight assay. For the enzyme assay, 0.5-ml. aliquots of the culture were pipetted into tubes containing 0.5 ml. chloramphenicol solution (50 μ gm./ml.) in 0.01 M sodium phosphate (pH 7). After toluene treatment at 37° C., 4 ml. of a solution of 2.5×10^{-3} M *o*-nitrophenyl- β -D-galactoside in 0.01 M sodium phosphate were added and the tubes incubated for a measured time, until the desired intensity of colour had developed. The reaction was stopped by the addition of 5 ml. of 0.4 M sodium carbonate. After centrifuging the cells, the optical density was measured at 420 m μ . One unit of enzyme is the amount which, under these conditions, hydrolyses 1 μ mole *o*-nitrophenyl- β -D-galactoside per min. The galactosidase activity, *Z*, in units galactosidase per ml. is plotted against dry-weight of bacteria, *X* in μ gm. per ml. The rate of induction is defined as the differential rate of synthesis, $p = \Delta Z / \Delta X$ (ref. 5). Cell density was determined by the aid

Fig. 1. Effect of lactose and its metabolites (glucose + galactose) on the synthesis of β -galactosidase induced by isopropyl-thio- β -D-galactoside. The exponentially growing cells, on maltose as carbon source, was induced with 10^{-3} M isopropyl-thio- β -D-galactoside (A) or with 10^{-3} M lactose (B). At the points indicated by an arrow, 10^{-3} M lactose (C) or 5×10^{-4} M glucose + 5×10^{-4} M galactose (D) was added respectively to the induced cells.

of a Pulfrich nephelometer. Standard curves were used to convert the readings obtained to dry-weight of bacteria per ml.

As shown in Fig. 1, the rate of synthesis of β -galactosidase induced by isopropyl-thio- β -D-galactoside is greater ($P = 6.6$) than in the case of lactose of the same concentration ($P = 2.0$) if the cells were grown on maltose as carbon source. The addition of lactose to cells induced by isopropyl-thio- β -D-galactoside—although lactose is an inducer in itself—inhibits the synthesis of enzyme. From the kinetics of the inhibition, it is not the lactose itself which causes inhibition but its metabolic products, namely, glucose and galactose. This inhibitory effect is very similar to that described previously concerning the inhibition of constitutive β -galactosidase synthesis by enzyme repression².

If the result shown in Fig. 1 may be generalized, that is, in the case of a metabolizable inducer the rate of synthesis of the induced enzyme is being regulated not only by the structure and concentration of the inducer but also by its metabolites, then it may be assumed that the same inducer will show a different inductive activity in cells grown with different carbon sources.

As seen in Fig. 2, if glycerol is used as source of carbon, the inductive activity of lactose in small concentrations is nearly the same as that of isopropyl-thio- β -D-galactoside. If an increasing concentration of lactose is used, then the enzyme induced by it produces great amounts of hexose. The metabolism of the cell grown on glycerol is not able to utilize this excess of hexose, and in consequence it will inhibit the synthesis of the enzyme. This inhibition will be suppressed only when the excess of hexose is metabolized by the cell.

From a theoretical point of view it is very important that isopropyl-thio- β -D-galactoside is a non-metabol-

Fig. 2. Synthesis of induced β -galactosidase in cells grown on glycerol as carbon source. At the point indicated by an arrow, the exponentially growing cells were induced with 10^{-4} M isopropylthio- β -D-galactoside (A), or 2×10^{-4} M lactose (B), or 10^{-4} M lactose (C).

izable inducer, that is, no metabolite is produced by the induced enzyme that would enter the cell metabolism. Consequently, experiments carried out with such inducers will give no answer to the question whether the mechanism of the induction or its regulation is influenced or not by the metabolites of the inducer.

These investigations show that the rate and level of synthesis of the induced enzyme is determined by the ratio of the concentration of the inducer and of its metabolites, glucose and galactose, causing enzyme repression. Further investigations in this direction are in progress.

I thank Dr. J. Monod for the supply of the strain of *Escherichia coli* used in this work.

A Method for the Direct Detection of Proteolytic Enzymes after Electrophoresis in Agar Gel

SEVERAL methods have been developed for the detection of different enzymatic reactions in agar gel¹. The present communication describes a method for the direct detection of proteolytic enzymes following electrophoresis in agar gel.

The principle of the method is the following: after the electrophoretic separation of the enzyme

preparation, the agar plate is immersed in a bath containing a protein which is susceptible to degradation by the proteolytic enzyme. After incubation the plate is fixed, dried and coloured in the normal way². The sites on the plate possessing a proteolytic activity toward the chosen substrate are revealed as weakly or non-coloured zones against an evenly coloured background. This coloured background is due to the protein substrate which diffuses into the agar gel during the incubation. In the zone where the proteolytic enzyme is situated all, or a portion of, the substrate is degraded. The coloration in this zone is non-existent or weak because the products of the degradation are not fixed by the acid fixator nor coloured by amido black.

The experimental conditions (buffer, pH, ionic strength, etc.) used for the preliminary electrophoretic separation may differ from those employed for the detection of the proteolytic enzyme, as these two operations are completely independent. For optimum results with each enzyme preparation and corresponding substrate, it is necessary to adjust the reaction conditions, that is, the pH, the temperature and time of incubation, the substrate concentration and the quantity of enzyme employed.

Fig. 1. Agar electrophoresis. A, Proteolytic activity of a purified non-crystallized trypsin preparation ('Difco'); B, proteolytic activity of a twice-crystallized trypsin preparation (Nutritional Biochemical Corp.); bottom, photometric scanning of upper images: ---, A; ... , B.

The following examples illustrate two of the different types of application of the method.

The proteolytic activity of preparations of trypsin have been studied in the following manner: freshly prepared trypsin solution (100 μ gm. per analysis) were subjected to electrophoresis according to the technique of Grabar and Williams³ for 60 min. at a potential difference of 6–7 V./cm. in agar gel of 1 per cent containing sodium veronal buffer (pH 8.2, I/2 0.025). After electrophoresis the plates were immersed in a 0.5 per cent solution of casein in veronal buffer (pH 8.2, I/2 0.05) and incubated with occasional stirring for 45 min. at 25° C. They were then fixed for 2 hr. in a 50 per cent ethanol solution containing 3 per cent acetic acid, dried under filter paper and coloured by amido black⁴. The results obtained with two commercial preparations of trypsin are shown in Fig. 1. The heterogeneity of these preparations is obvious.

The proteolytic activity of an aqueous extract of rabbit spleen has also been studied by carrying out the electrophoresis at pH 8.2 and then incubating the plate in a solution of human serum albumin at pH 3.5 (the technical details of the experiment will be given elsewhere⁵). A parallel electrophoresis of the spleen extract was done and stained for protein in the usual way³. Fig. 2 shows that despite the heterogeneity of the spleen extract its proteolytic activity is localized in one well-defined zone, thus confirming the results of Lapresle and Webb⁶.

Fig. 2. Agar electrophoresis. A, Electrophoretic pattern of the proteins in an aqueous extract of rabbit spleen; B, proteolytic activity (P.A.) in the same extract, R, starting place

These two examples illustrate one advantage of this method. It permits one to determine if the heterogeneity of an enzyme preparation is due to the existence of several constituents possessing a proteolytic activity (Fig. 1) or to the presence of non-enzymatically active protein impurities (Fig. 2).

Neurohormonal Properties of Royal Jelly

ROYAL jelly has significance in polymorphic development of bees. Bee larvae fed on an overabundance of royal jelly develop into queens; those given food differing quantitatively and qualitatively become worker bees¹. Royal jelly has other interesting properties, for evidence is available of its therapeutic value in transplantable mouse leukaemia² and of the presence of an antibiotic³. These effects might be termed anti-growth properties. It is remarkable that royal jelly is stated to contain acetylcholine⁴ in an amount calculated to be about six times that found in the brain of insects⁴. Nothing is known about the origin of acetylcholine in royal jelly or indeed whether this substance, obtainable from bees other than those used by Henschler⁴, contains acetylcholine. The occurrence of a neurohormone in royal jelly is of considerable interest for it suggests that acetylcholine may have a function different from that associated with nervous transmission.

Partition chromatography and the frog rectus abdominis muscle were used to identify acetylcholine. Royal jelly was heated to boiling point in a small volume of distilled water, pH 3.9, and when the extract was cool, trichloroacetic acid was added to give a final concentration of 1 per cent. The extract was centrifuged at 4,000 r.p.m. for 5 min., the supernatant decanted and shaken with an equal volume of ether for four successive extractions. The resulting clear liquid was evaporated to a small volume *in vacuo* and spotted on Whatman No. 1 filter paper. For reference, standard solutions of acetylcholine were used with trichloroacetate, bromide or chloride associated anions. Chromatograms were run in wet butanol as the solvent, and choline esters were detected by the use of Dragendorff's reagent, which reacts to give a pink spot. The results show that extracts of royal jelly gave one spot with an R_F of 0.45 identical to that found with a solution of acetylcholine trichloroacetate. By use of the frog rectus abdominis muscle it was determined that 1 gm. of royal jelly contained an active substance equivalent in activity to 683 ± 64 μ gm. of acetylcholine bromide. The active substance was readily hydrolysed by bovine purified erythrocyte or cockroach acetylcholinesterase and destroyed by alkali and heating; stability was found at pH 3.9. Atropine reduced contraction of the frog muscle. On the basis of this evidence it is suggested royal jelly contains acetylcholine, thus confirming the report of Henschler⁴ for the royal jelly of European bees. It was determined that acetylcholine was not destroyed in royal jelly held in storage for about two years. The pH of royal jelly, 3.9–4.1, appears to be about optimal for the preservation of acetylcholine.

The hypopharyngeal glands of nurse worker bees are said to produce royal jelly¹. These glands and the post-cerebral glands were used as sources for choline acetylase. The synthesis medium contained optimum amounts of coenzyme A, transacetylase, acetylphosphate, choline salts, and phosphate buffer (pH 6.9). Glands dissected from bee heads were frozen immediately in 0.9 per cent potassium chloride and homogenized just before use. No synthesis of acetylcholine was found with gland extracts although brain tissue synthesized up to 50 mgm. acetylcholine per gm. of brain in 1 hr. Furthermore it was determined by use of a standard manometric technique, with 0.01 M acetylcholine as substrate, that glands did not contain acetylcholinesterase. It is concluded

that, although a hydrolysing esterase was absent, no evidence has been obtained for the presence of choline acetylase in gland tissue to account for the acetylcholine of royal jelly. Extra-cellular enzymic synthesis of acetylcholine could occur in the lumen of glands, but it is doubtful whether this would happen at royal jelly pH, for optimal choline acetylase activity occurs at pH 7.0–7.5 with acetate as the acetyl donor⁶.

Goldschmidt and Burkert⁷ report the occurrence of acetylcholine in honey. This fact dispels evidence of an especial property of the secretion of hypopharyngeal glands, but suggests that acetylcholine may be a necessary inclusion in both honey and royal jelly, for these substances are the natural food of bees. Disregarding the possibility that acetylcholine appears in royal jelly or honey during muscular activity of the pharynx necessary for the expulsion of these substances from worker bees, it could be that acetylcholine has ecto-hormonal properties. Acetylcholine has no apparent effect when injected into insects in high amounts, but the possibility exists that it has a muscarinic action on the gut of bee larvae, and in this way promotes rapid ingestion and movement of food. Choline as a hydrolysis product would provide a source of methyl groups for the process of transmethylation, which may be a factor in growth. In any event it would appear that acetylcholine of royal jelly and honey may have another purpose in insects different from that thought to be associated with the neurohormone in nervous tissue.

Effect of Fluoride on the Biogenesis of Thyroid Hormones

THE biogenesis of thyroid hormones occurs in several successive stages. Accumulation of iodine in the thyroid may be considered as the first of these, while the second is represented by the binding of 'active iodine' on the tyrosine radical, 3-moniodotyrosine being formed in the process. It would seem that a further enzymatic system¹ is responsible for the production of 3:5-diiodotyrosine, and a fourth phase in this biogenesis consists in the synthesis of iodinated thyronines into thyroxine, 3:5:3'-triiodothyronine, 3:3':5'-triiodothyronine and 3:3'-diiodothyronine. In addition to these biosynthetic enzyme systems intervening in the thyroid, it is necessary to mention also the deiodinating enzyme, acting selectively on iodinated tyrosines and the proteolytic enzymes which liberate amino-acids from the thyroglobulin.

Table 1. PERCENTAGE OF IODINATED AMINO-ACIDS AND IODIDE IN PANCREATIC HYDROLYSATES OF THYROGLOBULIN IN THE RAT ASSESSED CHEMICALLY (IODINE-127)

	Control (n = 4)	Fluorized (n = 7)
Start	9.9	11.2
3:5-Diiodotyrosine	47.6	46.5
3-Moniodotyrosine	23.2	23.5
Iodide	5.9	5.7
Thyroxine	8.7	8.9
3:5:3'-Triiodothyronine	4.3	3.6
Total iodine in the thyroid gland	6.73 μ gm	6.62 μ gm.

The present experiment bears on the effects of fluoride on the biogenesis of thyroid hormones in rats (females, weight 180–230 gm.). The animals received a daily dose of 2.2 μ gm. of iodine in their basic diet² or 0.2 μ gm. of iodine in a carbohydrate diet³ in addition to 750 μ gm. of fluoride given by means of a gastric tube in 1.0 ml. of water. Two months following the intraperitoneal application of 25 μ c. of iodine-131 without carrier, the rats were killed at various time-intervals by bleeding under ether anaesthesia. The thyroids were homogenized and hydrolysed by means of pancreatine at 38° C. for 24 hr. 0.03 ml. of the hydrolysate was transferred directly to Whatman No. 1 chromatographic paper and developed in the *n*-butanol/dioxane/ammonia system (4:1:5) at 35° C. (ref. 4). The chromatograms were then analysed on an automatic radiopaper chromatographic recorder (Frieske-Hoepfner). The percentage representation of iodinated amino-acids was assessed by chemical methods. This same procedure was also used for the assay of the protein-bound and total iodine-levels in serum and in urine⁵.

The quantity of ingested fluoride had no effect either on body-weight, weight of thyroid, total composition of iodinated amino-acids or amount of iodide present in the thyroid (Table 1); it was also without effect on the iodine excreted in the urine and on the protein-bound and total iodine-levels in the rats receiving 2.2 μ gm. of iodine daily. At the daily dose-rate of 0.2 μ gm. of iodine, the protein-bound iodine-level in fluorized animals (*n* = 12) was lower than in the controls (*n* = 7), receiving the same diet (*P* < 0.05). In both groups, however, investigation with iodine-131 revealed a reduced rate of biogenesis of thyroxine and 3:5:3'-triiodothyronine within 12 hr. following administration of iodine-131. Fig. 1 shows a characteristic autoradiochromatogram of thyroglobulin hydrolysates of rats with a daily iodine intake of 2.2 μ gm. The animals were killed 64 min. after the administration of iodine-131. The statistical evaluation of differences in rats receiving a daily intake of 0.2 μ gm. of iodine is given in Table 2. Fluorized rats showed a significantly decreased amount of thyroxine (*P* < 0.01) and of 3:5:3'-triiodothyronine (*P* < 0.05) as against the controls. At a later date, after the application of iodine-131, the amount of thyroxine and 3:5:3'-triiodothyronine was the same in both the groups without regard to the diet.

Table 2. THYROXINE AND 3:5:3'-TRIIODOTHYRONINE RATIOS IN CONTROLS AND FLUORIZED RATS WITH DAILY INTAKE OF 0.2 μ GM. OF IODINE, 8 HR. 32 MIN. FOLLOWING APPLICATION OF 25 μ C. OF IODINE-131

	Control (n = 2)	Fluorized (n = 6)
Thyroxine	21.31 $\pm$ 2.75*	8.00 $\pm$ 3.20
	<i>t</i> = 5.24	<i>P</i> < 0.01
3:5:3'-Triiodothyronine	9.37 $\pm$ 3.16	4.43 $\pm$ 1.69
	<i>t</i> = 3.04	<i>P</i> < 0.05

* The values were obtained planimetrically and are given in sq. cm.

Fig. 1. Chromatograms of hydrolysed thyroglobulin in control and in fluorized state with daily iodine intake of 2.2 μ gm., 64 min. following administration of 25 μ c. of iodine-131. 3:5:3'- T_4 = 3:5:3'-triiodothyronine; T_4 = thyroxine; I^- = iodide; MIT = 3-moniodothyronine; DIT = 3,5-diiodothyronine

This finding is considered as confirmation of the fact that a special enzymatic system, which it is possible to inhibit by means of fluoride, is responsible for the synthesis of thyroxine and 3:5:3'-triiodothyronine.

BIOPHYSICS

A Water-insoluble Trypsin Derivative and its Use as a Trypsin Column

THE conversion of enzymes into water-insoluble products possessing specific catalytic activity is of interest since such 'water-insoluble enzymes' may readily be removed from the reaction mixture, and can be used for the preparation of columns with enzymic activity. If stable, they may be employed repeatedly to induce specific chemical changes in relatively large amounts of substrate. Adsorption techniques were applied to combine enzymes with insoluble carriers¹. These procedures led, however, to partial denaturation and resulted in preparations from which the reversibly adsorbed enzyme was removed while in contact with substrate. In order to strengthen the linkage between enzyme and carrier their attachment by chemical covalent bonds seemed preferable. Such links should obviously be carried out by functional groups non-essential for enzymic activity. Furthermore, the attachment of the enzyme to the carrier by flexible polymeric side-chains

would ensure free movement of the catalyst molecules in the reaction mixture.

Various attempts to attach antigens and antibodies by chemical bonds to water-insoluble high molecular weight compounds have been reported². The immunologically active columns obtained were used in the purification of the corresponding antibodies and antigens, respectively. So far as we are aware, however, only one paper deals with the chemical binding of enzymes to water-insoluble polymers³. Polyaminostyrene was used as carrier, and enzymes such as pepsin and carboxypeptidase were coupled with the polymer through azo bonds. The chemical properties as well as the enzymic activity of the final products were poorly characterized.

In the following we describe the preparation of a water-insoluble trypsin making use of the ideas mentioned above. A polytyrosyl trypsin containing tyrosyl peptide side-chains was prepared by initiating the polymerization of N-carboxy-L-tyrosine anhydride with trypsin. The trypsin derivative thus obtained was water-soluble and retained full enzymic activity. On coupling with a diazotized copolymer of *p*-aminophenylalanine and leucine it yielded the required water-insoluble trypsin. The latter served for the preparation of an active trypsin column.

Crystalline trypsin (75 mgm.) was dissolved in phosphate buffer, pH 7.2, ionic strength 0.25 (8 ml.), and the solution was mixed with N-carboxy-L-tyrosine anhydride⁴ (80 mgm.) in dioxane (2 ml.). The mixture was kept at 2° C. for 24 hr. with magnetic stirring. Afterwards it was dialysed for five days against a large volume of 0.0025 *N* hydrochloric acid and was then lyophilized. The polytyrosyl trypsin obtained was free of monomeric tyrosine and of low molecular weight tyrosine peptides. A comparison of the ultra-violet absorption of polytyrosyl trypsin at 293.5 m μ in 0.1 *N* sodium hydroxide with that of trypsin revealed that the tyrosine content of the enzyme had increased from 2.8 per cent to 9.0 per cent.

The copolymer of *p*-amino-DL-phenylalanine and L-leucine was prepared by copolymerization of α ,N-carboxy-*p*-amino-N-benzoyloxycarbonyl-DL-phenylalanine anhydride⁵ (3.5 gm.) and N-carboxy-L-leucine anhydride⁶ (1.5 gm.) in dioxane (100 ml.) using triethylamine (0.1 ml.) as initiator. The product formed after standing for three days at room temperature was precipitated with water, dried and the benzoyloxycarbonyl groups were removed with anhydrous hydrogen bromide in glacial acetic acid. Hydrolysis with 6 *N* hydrochloric acid for 24 hr. yielded *p*-aminophenylalanine and leucine in a molar ratio of 1:5. The copolymer was diazotized with nitrous acid and the diazonium salt formed precipitated at pH 7.5 with a concentrated sodium acetate solution. Coupling with polytyrosyl trypsin was effected in phosphate buffer, pH 7.2, ionic strength 0.25, at 2° C. with magnetic stirring. The reaction mixture was kept in the cold for 20 hr. and the light brown water-insoluble trypsin was separated by centrifugation and washed with 10 per cent sodium acetate solution, followed by 0.0025 *N* hydrochloric acid until no tryptic activity could be detected in the washings. The water-insoluble preparation was shown to contain 21 per cent protein as estimated from the amount of valine determined chromatographically⁶ after acid hydrolysis.

The rate of hydrolysis of benzoyl-L-arginine methyl ester (4 mgm. per ml.) at pH 7.8 and 25° C., by

water-insoluble trypsin (1 mgm. per ml.), was equal to that by 0.045 mgm. per ml. crystalline trypsin. Since 1 mgm. water-insoluble trypsin contains 0.21 mgm. bound protein, the catalytic activity of the latter towards benzoyl-L-arginine methyl ester amounts approximately to a fifth of that of the free enzyme. The enzymic activity of water-insoluble trypsin remained practically unaltered when kept under 0.0025 *N* hydrochloric acid at 2° C. for several months. The remarkable stability of the water-insoluble trypsin is most likely due to the blocking of the ϵ -amino lysine groups of the enzyme on one hand, and to the fixation of the enzyme molecules to the water-insoluble copolymer on the other. The former leads to a decrease in the number of enzyme peptide bonds susceptible to tryptic digestion, while the latter inhibits interaction between trypsin molecules, thus diminishing autodigestion. Complete inactivation of water-insoluble trypsin could be effected by heating to 100° C. for 15 min. at pH 7.5. Addition of an excess of soybean or pancreatic trypsin inhibitor caused only partial inhibition of the enzymic activity.

A trypsin column of 0.8 cm. diameter and 5.0 cm. height was prepared by mixing water-insoluble trypsin (20 mgm.) with an inert polyvinyl resin ('Geon, 428', B.F. Goodrich Co.) (2.0 gm.) in 0.0025 *N* hydrochloric acid (20 ml.) and by pouring the mixture into a glass tube. Prior to use the column was washed with the suitable buffer. The effect of rate of flow of substrate on the degree of hydrolysis was tested in the case of L-arginine methyl ester. When a solution containing 7.0 mgm. substrate per ml. phthalate buffer of pH 6.0 and ionic strength 0.19 was passed through the column at 25° C. at different flow-rates (0.125 ml.-1.0 ml. per min.) the percentage of ester hydrolysed was found to be inversely proportional to the rate of flow. The column had retained full enzymic activity, even after the hydrolysis of as much as 4.0 gm. of L-arginine methyl ester during a period of two weeks.

On passing through the column a solution of poly-L-lysine hydrobromide (10 mgm. per ml. phosphate buffer, pH 7.4, ionic strength 0.13) at a rate of 1 ml. per hr., the effluent was found to contain dilysine, trylsine, tetralysine and traces of lysine⁷. Protamine and insulin oxidized by performic acid could be digested under similar conditions to products identical to those formed by normal tryptic digestion as detected by paper chromatography.

To test the action of the water-insoluble enzyme on a native protein, water-insoluble trypsin (1 mgm.) was mixed with a solution of 0.68 per cent rabbit myosin in 0.5 *M* potassium chloride, 0.03 *M* phosphate, pH 7.0 (5 ml.), and the reaction mixture was incubated at 22° C. After given time-intervals, 1-ml. aliquots were withdrawn, the water-insoluble trypsin was removed by centrifugation and the ultracentrifuge pattern of the supernatant was determined in a Spinco model-B ultra-centrifuge at 56,100 r.p.m. The pattern obtained after a digestion period of 200 min. showed clearly the presence of light and heavy meromyosin, and was similar to that formed by tryptic digestion of the myosin solution with 0.04 mgm. crystalline trypsin for 10 min.⁸

The trypsin column described here may be of particular use in the degradation of peptides and proteins for amino-acid sequence analysis. Since the various lysyl and arginyl peptide bonds of proteins and peptides may differ in their susceptibility towards

trypsin, it is possible that preferential hydrolysis might be achieved by varying the rate of flow of the substrate through the trypsin column. Finally, it is possible that the principle used for attaching the enzyme with the aid of linear polymeric chains to a water-insoluble carrier might be used for the preparation of other water-insoluble proteins with biological activity. In such cases it will be of primary importance to determine the functional groups which are non-essential for the activity, and to find the suitable chemical reactions for forming the desired biologically active water-insoluble products.

This investigation was supported by grant A-3083 of the National Institutes of Health, U.S. Public Health Service, and grant AF 61(062)-391 of the U.S. Air Force.

PHYSIOLOGY

Phosphorylation as a Factor in promoting the Crabtree Effect in the Amytal Ascites Sarcoma of White Mice

CRABTREE¹ has demonstrated an inhibition of oxygen consumption in several different malignant tissues following the addition of glucose. Many attempts have since been made, especially during recent years, to explain the mechanism of this phenomenon. Certain workers^{2,3} regard adenine nucleotides, others^{4,5} inorganic phosphorus, as responsible for the production of the Crabtree effect and postulate a competition between the oxidative and glycolytic systems for one of these substances. Acs *et al.*⁶ have suggested that a location of enzyme systems unique for the cells involved also plays some part in producing the inhibitory effect.

The hypothesis of a direct competition for adenosine diphosphate seems to be disproved by the experimental observation that the inhibitors of glycolysis do not counteract the Crabtree effect, although they completely stop the glycolytic phosphorylation of adenosine diphosphate. The significance of the role of inorganic phosphorus, on the other hand, seems to be substantiated by the experiments of Brin and McKee⁴, who succeeded in partially arresting the Crabtree effect by raising the concentration of inorganic phosphorus to 55 mmoles/l.

Data are very scanty as regards changes in the level of inorganic phosphorus during the incubation of ascites cells with glucose, and even the available reports refer to cases observed in phosphate-buffered media⁷.

Fig. 1. Percentage changes in the inorganic phosphorus content of ascites cells in the course of incubation without substrate, with glucose (200 mgm. per cent), with fructose (200 mgm. per cent) and sodium succinate (0.02 M) regarding initial value as 100 per cent

We have studied changes in the inorganic phosphorus content of amytal ascites sarcoma cells occurring in the presence of different substrates without phosphate buffer. Incubation on endogenous substrate resulted in a significant increase of inorganic phosphorus; regarding the initial value as 100 per cent, it went up to 187 per cent within 1 hr., while the level of inorganic phosphorus decreased to 97 per cent in a medium containing 200 mgm. per cent of glucose. Fructose in a similar concentration is likewise capable of preventing the release of inorganic phosphorus, while both sodium succinate and sodium fumarate fail to prevent any effect (Fig. 1). This change in the level of inorganic phosphorus is not affected by the presence of either sodium fluoride or monoiodoacetic acid. Unlike glucose or fructose, fructose-1,6-diphosphate is unable to prevent the accumulation of inorganic phosphorus; this cannot be ascribed to a possible impermeability to phosphorylated sugars since similar results have been observed in homogenized systems as well. A typical change in inorganic phosphorus occurs if ascites cells are first incubated for an hour without

Fig. 2. Effect of glucose on changes in inorganic phosphorus contents of ascites cells. Glucose was added to cells after their incubation for an hour on endogenous substrate

substrate and glucose is added thereafter: inorganic phosphorus increases rapidly in the first phase, and drops to the initial level 10 min. after the addition of glucose (Fig. 2).

All these observations substantiate the significance of phosphorylation as a factor responsible for the Crabtree effect. Phosphorylation and not complete decomposition of the sugars is necessary for the production of the effect, since—apart from glucose, fructose and mannose which undergo phosphorylation and metabolism—2-deoxy-D-glucose, too, is capable of provoking the Crabtree effect⁷, although 2-deoxy-D-glucose undergoes phosphorylation without suffering complete breakdown. The role of phosphorylation is further emphasized by the fact that galactose, which gains access to the cells but undergoes no phosphorylation, fails to elicit the Crabtree effect⁷. Nor is it reduced by glucosone which, while being bound to the hexokinase of the Krebs-2 ascites cells, is phosphorylated only to a very moderate extent⁸.

New Evidence for a Cholinergic Process in Sympathetic Transmission

RECENTLY a cholinergic mechanism has been proposed in sympathetic transmission¹⁻³. This suggestion was based on the following pieces of evidence. Sympathetic nerves contain cholinergic fibres⁴. Acetylcholine can exert a sympathomimetic effect acting at sites beyond the sympathetic ganglion cell, and this action depends on the presence of a store of catecholamine in the peripheral tissue⁵. Larger doses of acetylcholine can block the response to stimulation of postganglionic sympathetic fibres⁶. It was visualized that acetylcholine liberated from the endings of the cholinergic sympathetic fibres would impinge on a store of noradrenaline in the vicinity of the effector cells to bring about a final adrenergic response.

MacIntosh, Birks and Sastry⁷ have shown that the drug hemicholinium inhibits the synthesis of acetylcholine in brain tissue, and that this effect of hemicholinium produces failure at sites where acetylcholine is a neurohormone. Hemicholinium injection into animals caused death by respiratory paralysis, and other effects similar to those of tetanus and botulinum toxins⁸. The addition of hemicholinium to the fluid perfusing the cat's superior cervical ganglion led to failure of transmission and simultaneously the rate at which acetylcholine was released decreased⁹. Hemicholinium produced block at the neuromuscular junction and at parasympathetic nerve endings^{5,7-9}. The action of hemicholinium in inhibiting acetylcholine synthesis could be reversed

Fig. 1. Contractions of the guinea pig vas deferens in response to stimulation of the hypogastric nerve with 2-msec. pulses at 20/sec. for 10-sec. periods at 2-min. intervals. Each point is the mean of two-four experiments. After hemicholinium (20 μ gm./ml.) the responses gradually decreased. The failure of transmission persisted after the bath was washed out at the 100th min. Choline (100 μ gm./ml.) restored the response to nerve stimulation.

by choline⁴. This finding could explain the effect of choline in restoring the response to nerve stimulation when hemicholinium had produced a failure of transmission⁵⁻⁸.

We have investigated the effect of hemicholinium on the response to stimulation of a sympathetic nerve in order to test the proposal of Burn and Rand that a cholinergic process is involved in sympathetic transmission.

We chose for this investigation the isolated vas deferens of the guinea pig with the postganglion sympathetic hypogastric nerve attached. (This preparation was developed by Dr. S. Hukovič, working in the Department of Pharmacology, Oxford.) The vas deferens was suspended in an organ bath and the nerve stimulated with 2-msec. pulses at supramaximal strength for periods of 10 sec. every 2 min. The amplitude of the contraction of the vas deferens in response to nerve stimulation depended on the frequency of stimulation. With frequencies ranging from 7 to 20/sec., the response to successive periods of stimulation remained constant over long periods of time. A dose of tolazoline which specifically blocked the response to noradrenaline abolished the response to nerve stimulation. A dose of atropine which specifically blocked acetylcholine did not affect the response to nerve stimulation. Thus the hypogastric nerve to the vas deferens answers to the requirements of a sympathetic innervation.

When hemicholinium was added to the bath to make a concentration of 20 μ gm./ml., the responses of the vas deferens to hypogastric stimulation gradually decreased and were finally abolished (Fig. 1). The rate at which the responses declined increased with increasing frequencies of stimulation. Previous observations that failure induced by hemicholinium depended on the frequency of stimulation have been reported for transmission in the superior cervical ganglion⁵, and the neuromuscular junction⁹.

Wilson and Long⁸ have stated that hemicholinium is less active in blocking the response to nerve stimulation in sympathetically innervated structures than at parasympathetic nerve endings or at the

myoneural junction. Their experiments were made on organs *in situ*, whereas our observations have been made on an isolated organ. In order to make a comparison between a sympathetically innervated structure and the myoneural junction, we have examined the isolated diaphragm innervated by the phrenic nerve taken from the guinea pig. In this preparation a higher concentration of hemicholinium (200 μ gm./ml.) was required to produce a failure of transmission than was the case with the vas deferens. However, it is difficult to make comparisons because we observed again in this preparation that the rate at which failure was produced increased with increasing rates of stimulation. A further comparison of the action of hemicholinium on the response to nerve stimulation has been made in which we used a parasympathetically innervated structure. For this we used isolated rabbit atria with the vagus nerves attached¹⁰. Stimulation at 25 pulses/sec. applied to the vagi for periods of 1 min. duration at 4-min. intervals produced constant responses. After the addition of hemicholinium to the bath in a concentration of 40 μ gm./ml., we observed a gradually developing decrease in the response to vagal stimulation, and the response was almost abolished by the fifth period of stimulation.

When the responses of the vas deferens or the diaphragm to stimulation of the appropriate nerve had been completely blocked by hemicholinium, they could be restored by the addition of choline (0.1-1.0 mgm./ml.) to the bath.

In our experiments we have shown that hemicholinium produced a failure of transmission at two sites in which it is not disputed that acetylcholine is a transmitter, namely, in the innervation of the diaphragm by the phrenic nerve, and in the innervation of the atria by the vagus. The effect of hemicholinium in producing a failure of transmission in the sympathetic innervation of the vas deferens has two features in common with its actions at cholinergic sites; the failure depends on the frequency of stimulation, and it is reversed by choline. Thus there is additional evidence for the hypothesis of Burn and Rand that there is a cholinergic process operating at sympathetic nerve endings.

We are indebted to Dr. J. P. Long of the Department of Pharmacology, State University of Iowa, Iowa City, U.S.A., for a generous gift of hemicholinium. This work was done while one of us (M. J. R.) held a fellowship of the Life Insurance Medical Research Fund of Australia and New Zealand.

Histochemical Demonstration of the Mode of Action of the Alkaloid in Mussel Poisoning

It is generally accepted that the heat-resistant alkaloid which may be extracted from the digestive gland or liver of shellfish in coastal areas where poisoning of humans has occurred is responsible for the clinical picture in these cases. The same poison has been found in the dinoflagellate *Gonyaulax catenella*¹ on which the bivalves feed at certain times of the year, and the plankton has, therefore, been held responsible for the production of the toxin.

The exact mode of action and the nature of the poison are as yet unknown². It is described as an alkaloid with muscarine-like actions³, and is a potent neurotoxin, but, apart from the central and peripheral neurotoxic actions, Sapeika⁴ has also described a direct depressant action of the toxin on the myocardium and its conducting tissues.

In the present investigation the small amount of mussel extract (2 c.c.) which was used was kindly supplied to us by Dr. N. Sapeika. The extract was prepared from uncooked black mussels according to Daek's⁴ method.

On testing the extract, it was found that 0.6 mgm. injected intraperitoneally caused the death of rats weighing 70 gm. in a few minutes.

The extract contained 225 mgm. of the alkaloid per ml. Various dilutions of this extract were tested on 20- μ thick sections of cold, formalin-fixed rat brain and intercostal muscle. The acetylcholinesterase was demonstrated according to Gomori's⁵ modification of the Koelle method. The sections were pre-incubated in toxin plus buffer for 1 hr. before being transferred to the same concentration of the toxin in the substrate mixture. Control sections were pre-incubated in buffer alone. The degree of inhibition obtained and the concentrations used are listed in Table 1. The caudate nucleus was used to assess acetylcholinesterase inhibition.

Table 1. INHIBITORY EFFECT OF MUSSEL EXTRACT ON RAT BRAIN AND INTERCOSTAL MUSCLE

Concentration	mgm./ml.	Percentage inhibition
Rat brain		
0.1 ml. toxin/ml. substrate	22.5	100
0.07 " " "	15.75	100
0.05 " " "	11.25	100
0.04 " " "	9	100
Motor endplates		
0.04 ml. toxin/ml. substrate	9	± 10
0.027 " " "	5.075	0
0.02 " " "	4.5	0
0.018 " " "	3.6	0

In the concentrations used only slight inhibition was observed in the very strong motor end-plate acetylcholinesterase activity; but, due to the small amount available, this could unfortunately not be tested in a higher concentration-range. However, total inhibition of acetylcholinesterase was produced in the caudate nucleus in the entire concentration-range of the toxin studied. At the same time, marked inhibition was also observed in the supra-optic neurones.

No inhibition of pseudocholinesterase could be seen in the capillary walls or myelinated areas⁶.

From the above observations, it appears that the alkaloid has a very marked specific acetylcholinesterase inhibitory effect similar to some of the

organo-phosphorus compounds. In view of this, it is suggested that future cases of poisoning be treated with one of the oximes such as pyridinealdoxime methiodide⁷.

We are indebted to Dr. N. Sapeika for supplying us with the toxin and to Dr. R. Smit for advice.

This work was supported by a grant from the South African Council for Scientific and Industrial Research.

Nature of the Leucocytosis-inducing Factor in Plasma

It is now well known that fever¹ and leucocytosis², brought about by typhoid vaccine, are the result of the formation of at least two separate factors and not due to the direct action of vaccine (endotoxin) on the fever centre or on the bone marrow. Fukuda and Matsumoto³ have recently demonstrated that the two factors act quite independently of each other and that in adrenalectomized animals, in particular, in spite of the normal occurrence of fever response due to the formation of the endogenous fever factor, leucocytosis fails to occur, and the leucocytosis-inducing factor cannot be detected by the use of passive transfer technique. The formation of the leucocytosis-inducing factor was found to depend solely on the presence of glyccorticoids. Moreover, the formation of this factor after the injection of vaccine could be inhibited by insulin administration, and conversely enhanced in an alloxan-diabetic state⁴. It was the object of the present work to examine whether or not this leucocytosis-inducing factor which is detectable in the circulating blood is identical with the 'leucocytosis-promoting factor' of Menkin⁵ which was isolated from sterile exudates.

Typhoid-paratyphoid vaccine for clinical use (0.1 ml./kgm.) was first administered intravenously to a rabbit weighing about 2 kgm. At the time when a pronounced leucocytosis occurred (usually 8 hr. after), the animal was bled from the well-arterized ear vein (25 ml. in 10 min.) and serum was obtained. This serum was found to be capable of inducing a prompt rise in leucocyte counts (pseudoeosinophilia) when given intravenously to a test rabbit (5 ml./kgm.). The promptness of the occurrence of leucocytosis without appreciable fever and preceding leucopenia is very characteristic and strongly suggests that this reaction differs greatly from the leucocytic response brought about by the vaccine itself or eventual pyrogenic contamination. The effectiveness of the leucocytosis-inducing factor did not diminish during dialysis through 'Cellophane' tubing against running tap water. Its activity was not reduced by heating at 57° C. for 30 min., but was completely lost at 100° C. within 30 min. The leucocytosis-inducing factor, like Menkin's leucocytosis-

Fig. 1. Effective protein fraction of factor serum and turpentine exudate

promoting factor, is thus non-dialysable and thermostable.

Next, protein fractions were prepared from the effective serum by the ordinary fractionation with ammonium sulphate and examined for their activity in inducing leucocytosis.

Each fraction, which had been dialysed and equilibrated with a physiological saline solution, was injected intravenously into test animals in an amount equivalent to 10 ml. of serum. As illustrated in Fig. 1, only a γ -globulin fraction precipitable by 35 per cent saturation of ammonium sulphate was found to be effective in producing the characteristic leucocytosis. This finding seemed to us very striking, for it has been reported that Menkin's leucocytosis-promoting factor is found in a pseudoglobulin fraction of the exudates⁶, being distributed between α_1 - and α_2 -globulin⁷.

For the sake of comparison, turpentine pleuritic exudate from rabbits which would contain Menkin's leucocytosis-promoting factor was also fractionated by the same method. The results of intravenous administration of each of the fractions corresponding to 5 ml. of the exudate (pH 7.4) are also given in Fig. 1. It will be seen that the activity is associated with the α - and β -globulin fractions, which are precipitable by 50 per cent saturation of ammonium sulphate. The pleuritic exudate from adrenalectomized animals was found to be also effective. The formation of Menkin's leucocytosis-promoting factor, therefore, does not appear to depend on the presence of glucocorticoids, forming a sharp contrast with the case of the leucocytosis-inducing factor.

It may therefore be concluded that there exist two distinct factors both responsible for the production of leucocytosis. One will be formed in the cir-

culating blood in response to typhoid vaccine or other pyrogenic large molecular substances, whereas the other is formed in inflammatory exudates by the injured cells, even in the absence of the adrenal. Although Menkin has expressed the opinion that the latter factor (leucocytosis-promoting factor) may enter the circulating blood stream and then comes to be responsible for the leucocytosis frequently associated with inflammatory processes, there is no likelihood that the leucocytosis-promoting factor enters the circulation in large quantities, except under conditions of stress such as epinephrine administration.

Details of the experiments concerning these problems will be published elsewhere.

Importance of Insulin and of the Adrenal Cortex in determining the Toxicity in Baboons (*Papio ursinus*) of Human Anterior Pituitary

GROWTH hormone administered to normal, diabetic or hypophysectomized dogs produces severe toxic reactions which may terminate fatally¹. Human anterior pituitary preparations may also precipitate severe toxic reactions in spontaneous human diabetes and mild reactions even in non-diabetics^{2,3}. Similarly, saline suspensions of acetone-dried, human anterior pituitary lead to fatal reactions in insulin-deprived, depancreatized baboons⁴. Cortisone prevents the adverse reactions of growth hormone in hypophysectomized dogs⁵, but not in diabetic baboons⁶.

During the course of our investigations into the endocrine control of the metabolic disorder induced by complete pancreatectomy in the baboon, we had occasion to administer human anterior pituitary to 2 normal and 3 adrenalectomized baboons, and to 15 baboons either with the hypophysis or the adrenal removed in addition to the pancreas. Unlike the normal dog, the normal baboon fails to develop any gross clinical reactions if treated with ten times the amount of human anterior pituitary necessary to produce death in the insulin-deprived, depancreatized baboon. In the presence of an intact pancreas, human anterior pituitary is well tolerated by adrenalectomized baboons maintained with doca and/or hydrocortisone and by hypophysectomized baboons. Indeed, unlike the dog, human anterior pituitary greatly improves the physical state of the hypophysectomized baboon. Furthermore, although human anterior pituitary induces an intensely fatty liver in the diabetic baboon, provided sufficient insulin is administered, the animal remains well. Doubly operated, adrenalectomized-depancreatized baboons receiving doca but no insulin are unaffected by

human anterior pituitary. However, if the latter baboons, in addition to doca, also receive hydrocortisone, then severe toxic reactions manifest themselves within 10–12 hr. and these may prove fatal if human anterior pituitary is continued. Hypophysectomized-depancreatized baboons deprived of insulin may die rapidly after the injection of human anterior pituitary.

From these several experiments, it would appear that the toxic effects of human anterior pituitary depend primarily on an insufficiency of insulin and on the presence of at least some 11-oxy corticosteroids akin to cortisone or hydrocortisone. The fact that toxic reactions develop in hypophysectomized-depancreatized baboons deprived of insulin but receiving human anterior pituitary would indicate that the adrenal cortex of the hypophysectomized-depancreatized baboon continues to secrete 11-oxy corticosteroids, albeit in reduced amounts, for several months at least after hypophysectomy.

We wish to express our appreciation to Dr. J. Friedman, Department of Forensic Medicine, University of the Witwatersrand, and to Dr. M. Prates, director of Pathological Services of Mozambique, for making available the human pituitaries.

Phosphate and Salt Uptake by Bakers' Yeast

UPTAKE of phosphate by *Saccharomyces cerevisiae* has three components as indicated by first-order kinetic analysis of uptake under steady-state conditions as a function of phosphate concentration. Two of these components, having Michaelis-Menten constants $K_m = 10^{-5}$ and 10^{-3} , respectively, are evident on a plot of rate of uptake m against $m/$ phosphate concentration¹ (Fig. 1). Action of glycolytic and respiration inhibitors, including anaerobiosis—illustrated by the action of iodoacetate (Fig. 1)—indicates that both these components are coupled to oxidative phosphorylation associated with the action of glyceraldehyde-3-phosphate dehydrogenase. The component reaction with $K_m = 10^{-5}$ is found to be rate-limited by formation of adenosine triphosphate, which acts as a competitive inhibitor in the oxidative phosphorylation, and the component with $K_m = 10^{-3}$ by the action of hexokinase, which becomes rate-limiting for utilization of adenosine triphosphate. The coupling of phosphate uptake with glycolysis, but not its components, was recognized by Strickland² and Goodman and Rothstein³. Rothstein⁴, in particular, has related the uptake to glycolytic activity at a membrane surface.

Fig. 1. Hofstee graph for aerobic accumulation of phosphate at concentration of 10^{-4} to 10^{-6} M by bakers' yeast in the presence of 0.3 M glucose at pH 4.0

Fig. 2. Effect of 0.1 M *p*-phenylenediamine on aerobic phosphate accumulation by bakers' yeast from a 2×10^{-6} M solution in the presence of 10^{-4} M glucose

A third component of phosphate uptake having $K_m = 10^{-6}$ is observed with great consumption of oxygen when phosphate and glucose concentrations are low. It is responsive to respiration inhibitors (Fig. 2), increasing, for example, in the presence of *p*-phenylenediamine by increase of site with constant rate of turnover, and is found to be coupled to oxidative phosphorylation associated with oxidation of cytochrome *b*. The contribution of this component to uptake with phosphate concentrations greater than 10^{-5} M in the presence of glucose (>0.01 M) is negligible. The conclusion is that in bakers' yeast the activity of the respiratory chain is coupled to only a minor extent to phosphate uptake at an external membrane surface.

That these observations are general for salt accumulation is indicated by rubidium uptake by bakers' yeast under aerobic and anaerobic conditions (Fig. 3). Anaerobiosis increases the concentration of sites without affecting rate of turnover.

Barley roots, in contrast to bakers' yeast, take up phosphate only under aerobic conditions. The sites of uptake in barley roots are associated with oxidative phosphorylation in the respiratory chain⁵. The mitochondria seem to be effective at a limiting membrane and simply might be embedded in that membrane. In bakers' yeast the respiratory chain, whatever its particulate nature, appears to be functioning inside the limiting membrane and acts in phosphate uptake chiefly as an oxidant for reduced diphosphopyridine nucleotide. Under anaerobic conditions the oxidation is chiefly accomplished by the action of alcohol dehydrogenase. Barley roots also form ethanol⁶, but the triose phosphate dehydrogenase action utilizing oxidized diphosphopyridine nucleotide is internal to the cells and thus not anaerobically functional.

Fig. 3. Accumulation of rubidium ions by baker's yeast from 10^{-8} M solution at pH 4.0 under aerobic and anaerobic conditions

The yeast cells used in this work were grown in pure culture, to eliminate a common and very troublesome bacterial contaminant, on beef extract peptone medium containing 0.15 M sodium chloride and with 0.3 M glucose as a substrate. The oxygen consumption was 2.3×10^{-8} mole oxygen/mgm. dry weight. Cells were washed once with 0.15 M sodium chloride and introduced at zero time into a salt solution containing phosphorus-32 or rubidium-85. Uptake was terminated by centrifuging (10 sec.) and washing.

HÆMATOLOGY

An Albumin Gradient Method for separating the Different White Cells of Blood, applied to the Concentration of Circulating Tumour Cells

THE albumin sedimentation method of Vallee *et al.*¹ has been applied to the problem of isolating tumour cells from the circulating blood². This method and its modifications involve the collection of the cells at an interface. When a variety of cells together with platelets are packed at an interface they are apt to sink or float as a unit. Such artefacts may seriously interfere with separation in a centrifugal field³. Moreover, we have found the cells to show morphological changes after prolonged centrifugation in contact with a foreign solution. It is therefore desirable to use a gradient method⁴.

The present method avoids interfaces, dispenses with the necessity for making up solutions of accurately known specific gravity, and exposes the cells for the shortest possible time to the minimum possible

concentration of foreign substances. The cells are suspended throughout in their own plasma.

16 ml. of venous blood is taken with a siliconed syringe into a siliconed vessel containing 4 ml. of 6 per cent dextran in saline ('Dextraven') with 40 mgm. of ethylenediamine tetraacetic acid dipotassium salt. A silicone rubber bung is inserted, and the contents mixed. The tube is stood for about $\frac{1}{2}$ hr. until the red cells have sedimented. The supernatant plasma containing the white cells is removed and centrifuged at 1,000 r.p.m. for 10 min. The procedure so far is that of Alexander and Spriggs⁵ except for the use of ethylenediamine tetraacetate instead of heparin in order to prevent platelet clumping. The deposit is resuspended in 0.5 ml. of its own plasma, and is referred to as the 'leucocyte suspension'. The supernatant plasma, which was poured off, is centrifuged again at 3,000 r.p.m. for 5 min. before being used in subsequent stages of the separation.

Bovine albumin solution is prepared as described by Roberts *et al.*⁶. We have used Armour's bovine plasma albumin (fraction V). The final concentration is immaterial provided that the solution has a higher density than the red cells; it should have a specific gravity 1.100 or above.

About 0.5 ml. of the albumin solution is placed in the bottom of a siliconed tube of 6 mm. bore, and an equal volume of the plasma is layered on top. Using a sealed-off Pasteur pipette (with an angle at the end) as a stirrer, the interface is broken, and the fluids are mixed by passing the stirrer up and down with gradually increasing amplitude, but avoiding the top and bottom of the column. A visible gradation in the colour of the column is used as a guide to the correct degree of mixing; the operation takes not more than 30 sec.

The white cell suspension is layered on to the column, and the tube is centrifuged for 15 min. at 3,000 r.p.m. By this time several layers have formed, as shown in Fig. 1.

The topmost layer consists of platelets with monocytes and some lymphocytes. This layer is often double, the upper part consisting almost entirely of platelets and the lower containing the mononuclear cells. Turk cells and any megakaryocytes which have retained their cytoplasm are also present in this layer.

The plasma between layers A and B is often clear, but it may contain cells, particularly lymphocytes and myelocytes if present.

Layer B consists of the polymorphonuclear leucocytes. The basophils are commonest near the top and the eosinophils near the bottom, but they do not segregate from the neutrophils. Bare megakaryocyte nuclei are usually found in layer B.

Layer C consists of red cells. This layer may be translucent, owing to the high refractive index of the medium; the red cells are not in fact hemolysed.

To find tumour cells, the whole of layer A together with all the fluid above it is pipetted off, diluted with plasma, and centrifuged until the cells are deposited. The deposit is then spread on slides, air-dried and stained with May-Grünwald and Giemsa. We have found that if a drop of the deposit from an

Fig. 1

Fig. 2

effusion containing tumour cells is added to a 16-ml. sample of blood and processed by the above method, the tumour cells can be recovered from above the platelet layer, sometimes practically pure. They are also present in numbers in the platelet-monocyte layer (layer A), but very few sink below this.

Fig. 2 shows a film of layer A from a patient with reticulosarcoma whose direct blood film was normal. Besides monocytes and platelets, two reticulosarcoma cells are shown. The photograph demonstrates the good cell preservation and the absence of platelet agglutinates.

Fig. 3

Fig. 3 shows a film of the polymorphonuclear leucocyte layer (layer B); red cells are practically eliminated. This layer is not used in the examination for tumour cells; but the photograph shows that the same method would be useful for the preparation of polymorphonuclear leucocyte suspensions for other purposes.

Properties of a Further Variant of Hæmoglobin M

HÆMOGLOBIN M, discovered in 1948 by Horlein and Weber¹, is an abnormal hæmoglobin of rare occurrence, three variants of which have since been identified^{2,3}. In two members of a family of Leipzig, Germany—a child and his father, the former having been clinically studied, on account of congenital methæmoglobinæmia, by one of us⁴—we were able to demonstrate a new type of hæmoglobin M.

Absorption spectra of destomatized hæmolysates made from washed erythrocytes of the patient and a normal adult control are shown in Fig. 1. After conversion of the oxyhæmoglobin to methæmoglobin by means of potassium ferricyanide, an absorption band at about 600 m μ (contrary to methæmoglobin A) and an inflexion at 540 m μ (similar to methæmoglobin A) appeared in the spectrum of the patient's hæmolysate. No difference was observed in cyanmethæmoglobin spectra of both hæmolysates. Isolation of methæmoglobin M in a pure state from the patient's hæmolysate (= hæmoglobin A + M), using starch block electrophoresis at pH 7.0 according to Gerald and George⁵, was not entirely satisfactory. A brown front and a slower portion of grey-green colour appeared in the otherwise unseparated spot. On elution, the grey-green portion spectrophotometrically showed an intensified absorption band near 600 m μ and a more distinct inflexion at 540 m μ . However, an inflexion in the region 640–620 m μ indicated that separation from methæmoglobin A had not been complete. On the evidence that 20–25 per cent of the patient's hæmoglobin is of type M (see below), the spectrum of 'pure' methæmoglobin M was calculated from the data of the patient's and a normal adult's methæmoglobin spectra (Fig. 1): there is a rather prominent peak at 602 m μ and a second absorption band at 540 m μ , the inflexion around 630 m μ being practically straightened.

Reaction of potassium cyanide ($1.45 \times 10^{-3} M$) and methæmoglobin A + M ($1.35 \times 10^{-5} M$) proceeded in two phases when followed at 630 m μ , pH 6.8: a very rapid one, identical with the reaction of methæmoglobin A, and a slow one (Fig. 2). At

Fig. 1. Methæmoglobin absorption spectra of destomatized hæmolysates of the patient (A + M, ●) and a normal adult (A, ○). ▲, Cyanmethæmoglobin (identical for A and A + M); ... , 'pure' methæmoglobin M calculated from A + M and A, assuming that 25 per cent of hæmoglobin M are present in A + M. Hæmoglobin concentration: 92 mgm./100 ml. = $1.38 \times 10^{-5} M$, pH 6.8 (phosphate)

Fig. 2. Reaction of methaemoglobin A + M and potassium cyanide followed at 600 mμ and at 630 mμ

600 mμ only a slow reaction was demonstrable, its half-time being 27.5 sec. under the above conditions. From the data of Fig. 1 it is evident that at 630 mμ the combined reactions of both methaemoglobins and cyanide will be measured, whereas at 600 mμ—near the isosbestic point of methaemoglobin A and cyanmethaemoglobin—the reaction of methaemoglobin A is optically eliminated, leaving cyanide combination of methaemoglobin M open to analysis. By calculating the amount of methaemoglobin A which corresponds to the reduction in optical density at 630 mμ in the rapid first phase of cyanide combination, it was estimated that 79.5 per cent of methaemoglobin A and 20.5 per cent of methaemoglobin M should be present in the patient's erythrocytes. Reaction velocity of cyanide combination of methaemoglobin M at pH 6.8 was found to be less than 1/100, as compared with normal adult methaemoglobin under appropriate conditions (cyanide $4.33 \times 10^{-4} M$; methaemoglobin $1.41 \times 10^{-4} M$).

Oxidation of haemoglobin M-containing oxyhaemoglobin solutions with potassium ferricyanide at pH 6.8 also proceeded in two phases, a rather rapid one and a slow one, the reaction velocity of the latter corresponding to the oxidation velocity of oxyhaemoglobin A. Similarly, comparative spontaneous oxidation of oxyhaemoglobin in patient's and normal adult's haemolysates at room temperature, pH 6.8, showed distinctly more rapid oxidation (reaction velocities 1:23) of oxyhaemoglobin M. Evaluation of the experimental data confirmed that haemoglobin M-content of the patient's haemolysate was about 23 per cent, which is in good agreement with the finding reported above.

The spectral characteristics of the methaemoglobin M described here are distinct from those of haemoglobin M_B of Gerald and George² and haemoglobin M_M of Pisciotto *et al.*³. Absorption bands near 600 mμ and 540 mμ are comparable to the findings of Gerald and George² in haemoglobin M_B. In contrast, haemoglobin M_B reacts rapidly with cyanide whereas this haemoglobin M reacts slowly.

In view of the spectrophotometric and reaction characteristics, it seems justified to assume that the

type of haemoglobin M described here is essentially different from haemoglobin M_B, haemoglobin M_B, and haemoglobin M_M. Following the general practice, we propose to designate it 'HbM_L' after the place of its origin. Spectral properties suggest that this type of haemoglobin M might be the same as the one previously studied by Hörlein and Weber¹, and Heck and Wolf⁴. It is to be noted that in the latter a rapid spontaneous oxidation has been demonstrated by Kiese *et al.*⁵.

Difference between γ-Globulins fixed on the Platelets of Patients with Idiopathic Thrombocytopenic Purpura and of those suffering from Disseminated Lupus Erythematosus or a Panhaematocytopenia

THE direct antiglobulin consumption test using leucocytes or platelets¹ is based on the indirect antiglobulin consumption test^{2,3}. It has been found to give positive results with both leucocytes and platelets from about 90 per cent of patients with disseminated lupus erythematosus and 30 per cent of cases of idiopathic panhaematocytopenia, but with platelets only from approximately 65 per cent of cases of idiopathic thrombocytopenia⁴.

It will be seen from Table 1 that when two different batches of anti-human-globulin serum (or Coombs's serum) were used, different results were obtained. Consumption of the anti-human-globulin serum was measured by testing against red cells sensitized with incomplete anti-D serum. It was found that whereas anti-human-globulin serum No. 1 was absorbed by the platelets of all three groups of patients, anti-human-globulin serum No. 2 was absorbed by the platelets of those suffering from disseminated lupus erythematosus or panhaematocytopenia, but not of those with idiopathic thrombocytopenic purpura.

Table 1

No. of cases		Anti-human-globulin No. 1 incubated with		Anti-human-globulin No. 2 incubated with	
		Leucocytes	Platelets	Leucocytes	Platelets
4	Normal, negative controls	—	—	—	—
2	D.L.E.	+	+	+	+
5	Panhaematocytopenia	+	+	+	+
6	Idiopathic thrombocytopenic purpura	—	+	—	—

+, Anti-human-globulin consumption; —, no anti-human-globulin consumption. D.L.E., disseminated lupus erythematosus.

The results obtained using anti-human-globulin serum No. 1 showed that γ -globulin had been fixed on the platelets of all three groups of patients. Using anti-human-globulin serum No. 2 it was shown that the antigenic structure of the γ -globulin fixed on the platelets of patients with idiopathic thrombocytopenic purpura was different from that on the platelets of patients in the other two groups. If we assume that the γ -globulin attached to the platelets is an auto-antibody, then these results would seem to show that there are two varieties of anti-platelet auto-antibodies.

PATHOLOGY

An Oncolytic Virus recovered from Swiss Mice during Passage of an Ascites Tumour

THE recovery of a tumour-destroying virus from mouse ascites was recently reported by Bennette¹. It was serially transmissible and seemingly non-pathogenic in the absence of neoplastic cells. Filtrates of ascitic fluids and extracts of cells which harboured the contaminant were highly destructive for the Ehrlich carcinoma and also five other tumours.

An agent with strikingly similar properties has been under observation in our laboratories for the past two years. The effects of this agent were first observed by one of us (G. S. T.) in Swiss *W* mice following long-continued passage of the mouse ascites tumour described by Nelson² in 1956. A number of sub-lines, maintained by intraperitoneal injection, were lost after the sudden appearance of abnormal ascitic fluid and aggregates of the tumour cells. Bacteriological findings were negative and a virus was indicated by passage of the active agent through Coors filters (No. 3). Most of the following observations were based, however, on the use of abnormal fluids sedimented at low speed to remove the tumour cells.

In practice, 12–15 gm. weanlings from the random-bred specific pathogen-free colony of Swiss mice maintained at the Rockefeller Institute were used. They were injected intraperitoneally in groups of 5 with 0.1 ml. of normal tumour fluid diluted 1:5 and the same volume of cell-free fluid containing the contaminant. The mice were usually killed on the seventh day after injection. Those which received the virus in high concentration were either normal at autopsy or showed a slight reaction. Suppression of the neoplastic cells in the peritoneal cavity was essentially complete. In some cases a solid tumour arose at the site of injection in mice held for a longer time. Injection of the virus in low concentration, declining activity being retained up to a dilution of 10⁻⁵, usually resulted in an irregular tumour growth. It was characterized by watery ascitic fluid with a reduced cell content and the appearance of a white membrane composed of aggregated cells, fibrin and

debris. The membrane was generally attached to the liver but less regularly extended downwards into the folds of the intestinal tract, with resultant binding and distension. During life, this reaction was accompanied by abdominal swelling and either rectal soilage or plugging. Most of the mice were otherwise normal, but an occasional animal showed external or internal signs of jaundice, yellow ascitic fluid, and yellow or white foci of necrosis in the liver.

Our observations were limited to the one tumour. In the presence of uncontaminated ascitic fluid, the virus was passaged intraperitoneally more than fifty times with similar findings. It was active in mature mice as well as in weanlings, but had little or no suppressing effect on solid tumours produced by intramuscular injection. The virus was tested in three additional mouse strains and showed no evidence of host specificity. It was recoverable from the livers of injected mice and readily maintained by intraperitoneal passage of liver suspensions. In the absence of tumour cells, it produced no detectable reaction in weanlings but continued to multiply in the liver. Phase microscopy revealed dense circular inclusions in the cytoplasm of some tumour cells from abnormal fluids. Electron micrographs, made with the co-operation of Dr. Man-Chiang Niu, showed single or multiple cytoplasmic nests of circular or elliptical particles with maximum diameters of 50–70 millimicrons.

Bennette¹ stated that his virus was not pathogenic in the absence of tumour cells, but his observations were limited to weaned mice. Our virus was similarly inactive in weanlings, but was highly pathogenic for nurslings 1–2 days old. Intraperitoneal injection of contaminated cell-free fluid was attended by high mortality (78 per cent of 42 mice) between the fifth and the thirteenth day. Mice that survived through the ninth day were under-developed and stunted. Some of them showed oily coats, with or without rectal soilage, and yellow or white necrotic foci in the liver. External and internal signs of jaundice were occasionally noted. Oral administration of the virus resulted in similar findings. Liver suspensions from the infected nurslings suppressed growth of the ascites tumour on combined injection in weaned mice.

The oncolytic virus was also recovered from a few mice during a minor outbreak of intestinal disease which occurred during the early development of the specific pathogen-free colony. The rigid quarantine observed in the maintenance of this colony precluded introduction of the virus by accidental contamination with experimental wastes. Outward signs of the naturally acquired disease were limited to nurslings and were similar to those induced by injection. Oily coats and yellow foci in the liver were again observed. Several female breeders which were nursing infected young but were normal in appearance also showed focal involvement of the liver at autopsy. The virus was demonstrable on combined injection in weanlings.

When first observed, it was thought that the oncolytic agent might be a member of the hepatoencephalitis group of murine viruses. The recovery of murine hepatitis virus from the same ascites tumour after prolonged passage in Princeton mice was reported by one of us (J. B. N.)³ in 1959. This relation was soon ruled out, however, by distinct behavioural differences. The intestinal and hepatic manifestations in nurslings were strongly suggestive of those produced by the hepato-encephalomyelitis

virus described in 1953 by Stanley, Dorman and Ponsford^{4,5} in Australia. Oily coats and yellow foci in the liver were characteristic features. The neurotropic properties of their virus were brought out by serial passage. The cerebral behaviour of our virus has not been fully studied. It seems probable that the Australian, British and American viruses are interrelated and are widely distributed in mouse colonies as latent invaders. Direct comparison of the three agents is clearly indicated.

Griseofulvin and Colchicine: Lack of Carcinogenic Action

DURING the investigation of the toxicology of griseofulvin, it was shown¹ that the antibiotic when given parenterally is a mitotic poison, in some respects similar to colchicine. Clinical investigation^{2,3} showed that this did not represent an acute toxic hazard in clinical use. Nevertheless, interference with mitosis seems to us to imply a greater possibility of carcinogenic action on long-term administration than is the case with compounds devoid of this property. Colchicine has not yet been studied adequately from this point of view, and it was decided to include a group treated with this drug in a study of the long-term effects of griseofulvin.

Four groups of albino, Wistar rats were used. All were newly weaned at the commencement of the experiment. Group I received colchicine, 0.5 mgm./kgm., twice weekly for 42 weeks. The colchicine was initially given subcutaneously in saline, but because of local necrosis the vehicle was changed to arachis oil after four weeks. Group II received saline and arachis oil as controls to Group I. Group III received a finely ball-milled suspension of griseofulvin as a 10 per cent w/v dispersion in 0.5 per cent aqueous mixture of 'Dispersol LN' and 'Dispersol OG', at a level of 200 mgm./kgm., twice weekly by intraperitoneal injection for 98 weeks. Group IV received the suspending agents alone as a control to Group III. Each group comprised 10 male and 10 female animals.

Colchicine proved toxic in the initial stages, but griseofulvin was well tolerated until the seventy-fifth week of the experiment when mortality began to mount. At the end of 52 weeks dosing, eight animals treated with colchicine, but only two treated with griseofulvin, had died. At the end of 78 weeks experiment, nine animals of each group treated with the drugs had died. Five animals given colchicine and seven given griseofulvin survived until the experiment was terminated at the end of the ninety-third week.

All animals were examined after death for the presence of tumours and, unless postmortem autolysis was advanced, blocks of all the major organs were fixed for histological examination. The following tumours were encountered: Group I: colchicine treatment; one fibroadenoma of mammary gland; Group II: control to colchicine, four adenomata of thyroid; one leiomyosarcoma of the vagina and one sarcoma at injection site; Group III: griseofulvin treatment, one adenocarcinoma of cervix uteri; Group IV: control to griseofulvin, one interstitial cell tumour of the testis.

In the animals treated with either griseofulvin or colchicine, the nuclei of the liver and stomach mucosa of some appeared rather more variable in size than is normally the case. Other pathological changes were found equally in control and treated groups.

Although the numbers in these experiments are relatively small, it is clear that neither griseofulvin nor colchicine is a potent carcinogen, and indeed these experiments give no evidence of carcinogenic action of any sort of either compound.

The Hedgehog as a Source of Human Ringworm

THE dermatophyte *Trichophyton mentagrophytes* has been isolated from a variety of animals, but although Georg¹ lists 18 wild and domestic mammals living in different geographical areas which are known to be spontaneous carriers of this pathogen, the hedgehog does not appear to have been included in any survey.

During March 1960 an adult female patient attended the mycological diagnostic clinic attached to this Department, complaining of ringworm, which she stated to have been contracted from a pet hedgehog. On examination, several raised itchy lesions were found, from which a pathogenic fungus was isolated. This was readily assigned to the genus *Trichophyton*, but less readily placed in a definite species. During the same month a similar isolate was obtained from a lesion on the wrist of an adult male, who had recently returned from a country holiday.

A series of 26 living and dead hedgehogs, collected in this area, were examined for the presence of a pathogenic fungus. Isolates of *Trichophyton*, similar in macroscopic and microscopic characters, were recovered from 7 (27 per cent) of the animals. Positive cultures were obtained from the quills of 4 and from the hair on the ventral body wall, the head or the ears of a further three. A hedgehog isolate (H1) was sent to Dr. Lucille Georg, Communicable Diseases Centre, Georgia, United States, who kindly identified it as *Trichophyton mentagrophytes*.

Mycelial fragments taken from the H1 strain were applied to an area of scarified skin on a guinea pig

and on a human volunteer. Rapidly spreading itching lesions were produced in both from which were recovered isolates identical with the H1 strain.

Hedgehogs were first introduced into the Dunedin district in 1885¹. Several further liberations were made in both islands of New Zealand, and these mammals have become very numerous in several areas. Their contact with man and his domestic animals may be greater than is generally realized, and there seems to be good evidence that the dermatophyte strains which they carry are transmissible to man. They appear to constitute a hitherto unrecognized source of human infections.

BIOLOGY

A Pacific Salmon (*Oncorhynchus gorbusha*) in Scottish Waters

On July 16, 1960, in a salmon bagnet at Altens fishing station on the sea-coast near Aberdeen, a fish was caught which was recognized as unusual. It was sent to the Freshwater Fisheries Laboratory at Pitlochry and then to the British Museum (Natural History), where it was identified as *Oncorhynchus gorbusha* (Walbaum)^{1,2}, the pink or humpback salmon, a species the natural distribution of which is along the Pacific coasts of North America and Asia from the Bering Straits to Peter the Great Bay and the Sacramento River.

This fish was 20½ in. in overall length with a standard length of about 450 mm., a depth of 135 mm., a width of 67.5 mm., and a weight of 4 lb. 2 oz. It is at once recognizable as distinct from either *Salmo salar* or *S. trutta* by the deeper body, more pointed snout and the presence of coarse oval black spots on the caudal fin; it differs from these and *S. gairdneri* (the rainbow trout) in the higher number of rays in the anal fin (A 17 as against 9–12, rarely 13 in *Salmo*) and of gill-rakers (26 on the whole of the first arch as against 24 or fewer in *Salmo*).

The scales, which are more numerous than in other species of *Oncorhynchus*—we counted approximately 170–174 in the lateral line—agree very well in structure with those of *O. gorbusha* figured by Gilbert³ and Davidson⁴, showing one winter band only and the inner circuli not crowded as in the typical freshwater parr-life of *Salmo*. The humpback's life-history is well known^{1,5-7}. It spawns in autumn (August–September in the River Amur). The eggs hatch in December, and the fry make their way to the sea as soon as they can swim, from April until June, at a length of 3.2–3.6 cm. They feed at first in water still brackish from the influence of the rivers (a phase consonant with the appearance of the first summer's growth of the scale) and then, at a length of 4–12 cm., move off to the open sea. Sexual maturity occurs at the end of the second year of life and no older fish have been caught in the spawning runs. Neither has any yearling fish been caught in fresh

waters. Marking experiments indicate a high percentage of returns to the natal stream, but some straying may occur if suitable rivers enter the sea in the neighbourhood of the natal stream⁴.

The Aberdeen fish, a male with enlarged testes, had the typical form and colouring of a 'clean' fish, with spots on the caudal fin only and none on the back, and without the kype and hump that develop at the spawning period. It is in the British Museum (Natural History).

We understand that, since 1956, the Russians have transferred very large numbers of Pacific salmon eggs, chiefly pink salmon, from Sakhalin Island north of Japan to the rivers of the Kola Peninsula. Up to the middle of September, they have had records of the return of some 75,000 fish to the rivers of the Kola Peninsula. There have also been reports of recaptures on the Norwegian coast, chiefly in the north, but extending as far south as Bergen, and in Iceland. Several thousand Pacific salmon have been caught on the Norwegian coast, though in Iceland the catches have been much smaller; probably less than fifty having been caught. It is, therefore, reasonable to assume that the pink salmon caught at Altens originated from one of the rivers of the Kola Peninsula.

We are grateful to Mr. G. G. J. Smart, of Messrs. Jos. Johnston and Sons, Ltd., of Montrose, for sending this fish caught in his firm's nets, to Mr. F. T. K. Pentelov (Ministry of Agriculture, Fisheries and Food) for helping to interpret the scales, and to Prof. G. V. Nikolsky and Dr. L. Rosseland for the information about catches in the U.S.S.R. and Norway respectively.

Interspecific Hybrids of *Tilapia*

WHITEHEAD's claim¹ to describe hybrids between *Tilapia nigra* and *T. zillii* in two waters in which both species had been introduced could be accepted only if supported by unequivocal evidence. His only evidence that *T. zillii* was one of the parents of the problematical fishes is that this was the only species other than *T. nigra* known to be introduced. We know enough of stocking accidents to place no reliance on this, especially when, as in this case, all the evidence points in another direction.

We have had the opportunity of studying Whitehead's fuller report, which he sent to one of us for criticism. From this we see that his statement¹ that "in most anatomical characters the hybrids resembled *T. nigra*" is true, but it would be better to say that these were characters of the section of the genus including *T. nigra* but not *T. zillii*. The divergences

from *T. nigra* are not in the direction of *T. zillii*. The body- and fin-colours¹ are in fact reminiscent of *T. leucosticta*, a mouth-brooding species which is an inhabitant of Lake Albert, the source of the East African stocks of *T. zillii*, and is known² to have been distributed with the latter in many East African waters from ponds at Kisumu. The toothed lower pharyngeal bone of the 'hybrid' is figured in Whitehead's full report, and he notes its resemblance to that figured for *T. leucosticta*³. The gill-rakers on the lower part of the anterior arch are 8-12 in *T. zillii*, 15-20 in *T. nigra*, 18-22 in the 'hybrids', 19-24 in *T. leucosticta*. The dorsal spines are 14-16 in *T. zillii*, 17-19 in *T. nigra*, 18-18 in the 'hybrids' and in *T. leucosticta*³.

Whitehead's claim to have effected the cross *T. zillii* × *T. nigra* in a pond rests on the presence there after six weeks of a female carrying eggs in the mouth, and this is not adequate evidence.

We suggest that many of the supposed hybrids were *T. leucosticta*—individuals inadvertently introduced with *T. zillii* or their progeny. It would be less surprising if some hybridization should occur between these and *T. nigra*, and some of the problematical fishes need re-examination with this possibility in mind, as Mr. Whitehead now agrees in correspondence with us.

Since we wrote the above, we have examined one of the 'hybrids' from Tebere ponds and find it indistinguishable from *T. leucosticta*.

Aquarium Behaviour and Breeding of *Hymenochirus*

*Hymenochirus*¹ is a genus of West African clawed aquatic toads which are considered to be closely related to *Xenopus*. In fact its members were originally described as belonging to the genus *Xenopus*².

Two years ago we were by chance able to obtain 15 young specimens of *Hymenochirus boettgeri* (Torn.) from a German importer of pet fishes, who had offered "afrikanische Kleinfrosche". As it turned out that nothing is known about the biology of this toad and that, so far as we can find, neither the breeding habits nor even the larvae have hitherto been described, we decided to study the aquarium behaviour of the toads instead of using them for tissue preparations.

Hymenochirus is a true aquatic toad, and in spite of the fact that it moves, with jumps, much more easily on dry land than does *Xenopus* it has never been possible to find a toad on the terrestrial part of the aquarium. There are no external sex differences in the genital region but the females are usually identified through their broad body form. The toads are apparently exclusively carnivorous and feed willingly on *Tubifex* worms, *Daphnia* and various kinds of gnat larvae, but also on different kinds of 'dead' food such as raw fish meat. The prey is

Fig. 1. Tadpoles of *Hymenochirus boettgeri*. The upper specimen is newly hatched, the lower one is 14 days old

obviously discovered and caught mainly with the aid of sight.

A vibration sound, which recalls that of *Xenopus*, is produced by the *Hymenochirus* males. In this case, however, short croaking periods alternate with silent periods. Each croaking interval terminates with a sudden rise in the pitch of the voice.

The males are often seen clasping females as well as other males in the typical *Xenopus* manner. Two attempts were made to induce spermiation and ovulation with luteinizing gonadotrophin, but without success. However, a sunny position of the aquarium has recently been sufficient to induce the spawning act, which has taken place during the night hours in a slightly alkaline water at 23-24° C.

Copulation is performed in a very peculiar manner. It occurs at the surface, usually in connexion with an inhalation of air, and starts with the female turning upside down with the male still clinging to her back. Her genital tract is now kept slightly protruding above the surface of the water and 2-10 eggs are deposited. After this process the couple return to the bottom. The surfacing is repeated about every second minute until the ovaries are apparently exhausted after about fifty times.

The eggs float on the surface but they do not stick together. They are about 0.9 mm. in diameter, with jelly about 1.5 mm. The larvae hatch after 2 days at a length of 3.2-3.5 mm. and are already pronouncedly pigmented at this stage. On the fourth day they start feeding on small aquatic animals, and much to our astonishment they took exclusively to a carnivorous diet during the whole larval period. Consequently the tadpoles of *Hymenochirus* are quite unlike those of *Xenopus* in this respect; they are unlike them in several other respects also. The filtering apparatus and the tentacles are omitted, they do not rest in the water in the typical oblique position, and the whole appearance is very fish-like.

It is clear that a study of the larval and adult biology of *Hymenochirus boettgeri* discloses a number of interesting differences between this species and *Xenopus laevis*. The adaptational and taxonomical significances of these diversities between the two genera of African pipid toads are under consideration.

Akinetoplastic Strain of *Trypanosoma evansi* produced by 'Prothidium'

SINCE Werbitzki's¹ observations that organic dyes having Ehrlich's orthoquinoid constitution caused disappearance of the kinetoplast in trypanosomes, several workers have, from time to time, reported the occurrence of both spontaneous and chemically induced strains of akinetoplastic *T. evansi*. Hoare² has fully discussed the early literature on the subject. Recently, Muhlpsfordt³ has published his observations on the effect of trypaflavin on the kinetoplast of various trypanosomes, and has shown that repeated administration of trypaflavin caused the complete disappearance of kinetoplast in *T. evansi* in 81 days. With other trypanosomes such as *T. equiperdum*, *T. brucei* and *T. gambiense* it took 54, 121 and 122 days, respectively, for the complete disappearance of this organelle.

Hoare and Bennett⁴ in 1938 showed that both spontaneous and induced akinetoplastic strains of *T. evansi* behaved like the normal ones, and that the absence of kinetoplast did not in any way alter the vital functions of the trypanosomes.

We have observed: (1) the quick disappearance of the kinetoplast from the otherwise normal strain of *T. evansi* as a result of treatment with a phenanthridinium compound 'Prothidium'; and (2) some apparent change in the functional activity of the akinetoplastic 'Prothidium'-treated strain.

The chemical composition of 'Prothidium' (Boots) is 2-amino-7-(2-amino-6-methyl-4-pyrimidylamino)-9-amino-phenyl-phenanthridine : 10 : 1-dimetho-bromide. 0.5 ml. of a freshly made 0.015 per cent solution of this drug was given subcutaneously to white rats weighing 100–125 gm. and showing a fair number of trypanosomes in the peripheral circulation. Three sets of experiments were carried out with two rats in each set. The ratio of kinetoplastic to akinetoplastic trypanosomes was estimated by counting a hundred trypanosomes in a stained smear made from one of the rats in each series. The akinetoplastic 'Prothidium'-treated strain is now being maintained in this laboratory and its functional behaviour so far observed (up to its 8th passage in rats) is reported as follows.

From Table 1 it will be seen that there was complete disappearance of the kinetoplast 44–60 hr. after treatment with the drug.

Table 1. PERCENTAGE OF KINETOPLASTIC (K) AND AKINETOPLASTIC (AK) TRYPANOSOMES AT DIFFERENT HOURS

	18 hr.	44 hr.	60 hr.
Series I	K.28 : AK 72	All akinetoplastic	
Series II	K.42 : AK 58	K.17 : AK 83	
Series III	K.34 : AK 66	K.20 : AK 80	All akinetoplastic trypanosomes disappeared*

* There was a relapse after 30 days when only AK forms were seen.

The akinetoplastic strain thus obtained was found to breed true when passaged through rats. Table 2 shows an alteration in the functional activity of the akinetoplastic 'Prothidium'-treated strain as compared to the normal.

From Table 2 it is apparent that the akinetoplastic trypanosomes multiply less rapidly than the normal strain, and this leads to longer survival after infection. Ultimately, however, the host succumbs to infection with the same clinical and pathological picture as seen in rats infected with a normal strain of *T. evansi*. This

Table 2. PREPATENT AND SURVIVAL PERIODS OF RATS INFECTED WITH NORMAL AND 'PROTHIDIUM'-TREATED STRAIN OF *T. evansi*

	Normal strain	'Prothidium'-treated strain
Incubation period in days in six rats	2, 2, 2, 2, 3, 3	5, 5, 6, 9, 12, 12
Survival time in days after first appearance of trypanosomes	3, 3, 3, 4, 3, 4	3, 5, 8, 9, 12, 12

akinetoplastic strain is now in its 8th passage, and the results are awaited with regard to its course of infection in larger animals (dog and horse).

Studies on Phycobilin Formation with Mutants of *Cyanidium caldarium*

VARIOUSLY pigmented mutants of *Cyanidium caldarium*, an organism classified in succession as a blue-green, green, and red alga by Hirose¹ and which Allen² regards as an anomalously pigmented chlorophyte, appear to be excellent experimental materials for study of the synthesis of phycocyanin.

Pigment analysis of light-grown wild-type *C. caldarium* confirmed Allen's² report of the presence of chlorophyll *a*, carotenoid, and phycocyanin in this organism. In addition, allophycocyanin was found to be present. Absorption spectra of the extracted pigments are shown in Fig. 1. Dark-grown wild-type cells, unlike those reported by Allen², have been found to yield measurable amounts of chlorophyll *a* as well as carotenoid. As in the work reported by Allen² no phycobilins have been found in dark-grown wild-type cells. Mutant forms were obtained by exposure of wild-type or mutant cells to ultraviolet light. Absorption spectra of whole-cell suspensions of the wild and mutant types are shown in Fig. 2. Solutions of individual pigments were obtained as follows: (a) Cells were broken by grinding with polishing alumina or by means of a 10 kc./s. Raytheon sonic oscillator. (b) The chlorophyll and carotenoid pigments were then extracted in methanol and petroleum ether and separated on a sugar column developed with petroleum ether and *n*-propanol after the method described by Strain³. (c) The water-soluble phycobilins were separated on a calcium phosphate column⁴ developed with 0.06 *M* sodium phosphate. Absorption spectra of extracted pigments and whole-cell suspensions were determined with a Cary recording spectrophotometer, model No. 11. The opal glass procedure of Shibata *et al.*⁵ was used for the determination of absorption spectra of suspensions of intact cells. The organisms were grown at room temperature or at 43°C. on a medium similar to that used by Allen², to which 1 per cent glucose was added.

Four general types of variant forms have been found.

(1) *Dark-greening mutants*. Cultures of wild-type cells grown in darkness are yellow; carotenoid and traces of chlorophyll are detectable spectrophotometrically.

Fig. 1. Absorption spectra of pigments of wild-type *Cyanoindium caldarium*. (Chlorophyll *a* and carotenoid in petroleum ether; phycobilins in water.) —, Chlorophyll *a*; ---, phycocyanin; . . ., allophycocyanin; — · —, carotenoid

metrically. The 'dark-greening mutants', as represented by mutant III-D-2 (Fig. 2), are, however, visually green when grown in the dark. Cells of this mutant contain both chlorophyll *a* and carotenoid pigments, and like the dark-greening S-1 and S-5 *C. caldarium* mutants described by Allen³, phycocyanin is also formed. The level of all pigments in the dark-grown, dark-greening mutant is lower than in light-grown wild-type cultures; however, light-grown cultures of the dark-greening mutants consistently accumulate more of each pigment than similarly grown wild-type cells.

(2) *Phycobilin-less mutants*. Light-grown cultures of this variant form, represented by mutant III-C (Fig. 2), accumulate chlorophyll *a* and carotenoid pigments but no measurable phycobilins. The absorption band seen at 615 mμ in spectra of whole-cell suspensions of this mutant appears to be that of a minor band of chlorophyll *a*. Absorption spectra of fractions obtained by calcium phosphate chromatography of aqueous extracts of ground III-C mutant cells appear to confirm the absence of phycobilins in this mutant.

(3) *A chlorophyll-less mutant*. The obligately heterotrophic mutant, GGB (Fig. 2), produces phycobilins and carotenoid pigments when grown in light, but no chlorophyll has been found. Ultra-violet irradiation of this mutant has yielded the following variant cell type.

(4) *A chlorophyll-less, phycobilin-less mutant*. Light-grown cultures of mutant GGB-Y (Fig. 2) accumulate

no chlorophyll or phycobilin pigments. Carotenoids are found to be present in these cells.

Studies of the action spectrum for the formation of phycocyanin in the chlorophyll-less mutant (GGB) have shown that cultures exposed to 30,000 foot-candle min. of either 450 or 600 mμ light form this pigment; whereas a similar exposure to light of 550, 660 or 700 mμ results in no measurable formation of phycocyanin. The effects of light of other wave-lengths have not yet been investigated. The effectiveness of 600 mμ light in formation of phycocyanin in *C. caldarium* is in agreement with the recent work of Hattori and Fujita⁶, in which it was noted that the effective part of the spectrum relative to phycocyanin and allophycocyanin formation in *Tolypothrix tenuis* lies somewhere between 550 and 700 mμ. It was, however, further noted by Hattori and Fujita⁶ that blue light, ranging in wave-length from 400 to 550 mμ, was ineffective in inducing the formation of phycocyanin and allophycocyanin in *T. tenuis*. The screening effect of the chlorophyll in cells of *T. tenuis* might account for the difference in the

Fig. 2. Absorption spectra of cell suspensions of *Cyanoindium caldarium* using the opal glass technique of Shibata (ref. 5). Cell types: —, wild; ---, III-D-2; . . ., III-C; ---, GGB; — · —, GGB-Y. Wild and III-D-2 spectra are at half-strength

observations that phycocyanin is formed in light of 450 m μ by the chlorophyll-less *C. caldarium* mutant GGB, but not by *T. tenuis*.

Hattori and Fujita⁴ suggested, on the basis of the ineffectiveness of blue light for phycobilin formation, that the substance acting in the formation of phycocyanin and allophycocyanin could be neither chlorophyll nor carotenoids in *T. tenuis*. The existence of the phycobilin-producing chlorophyll-less *C. caldarium* mutant described here as well as the data on the action spectra provide evidence that phycocyanin and allophycocyanin are not derived from chlorophyll.

Further work on the action spectra for phycobilin formation in wild-type and mutant *C. caldarium* cells is in progress. The limited data from the present work are not inconsistent with the possibility that one or more haem proteins might serve as photo-receptors (and perhaps as precursors) in the biosynthesis of phycobilins.

We wish to extend our thanks to Dr. Mary Belle Allen, who supplied the original culture of *Cyanidium caldarium* used in this work, and for the support provided in part by grants from the National Science Foundation and the United States Public Health Service, Institute of Arthritis and Metabolic Diseases (A-1010), and in part by the Dr. Wallace C. and Clara A. Abbott Memorial Fund of the University of Chicago.

Biochemical Classification of Yeasts

IN a discussion of yeast taxonomy from a biochemical point of view, Barnett¹ made some valuable suggestions for its improvement. These emphasized: (1) the possibility that each group of yeasts may require its own particular set of biochemical tests; (2) that many of the biochemical tests now used in yeast taxonomy are of dubious value; (3) that our present understanding of the diverse biochemical processes carried out by these organisms is often very inadequate. The author accepted the view that taxonomy should embody a synthesis of results from various fields of inquiry, and that the progressive growth of knowledge necessarily renders any system of classification impermanent.

However, in a recent criticism of the methods employed by the Dutch school of yeast taxonomy^{2,3}, Barnett⁴ now suggests that an improved and stable classification of the yeast fungi could eventually be achieved by employing exclusively biochemical criteria. The diagnostic value of these criteria in the comparative study of yeasts is regarded as being self-sufficient, since "imprecise and subjective morphological observations are avoided and there is no need

to search for spores". It is not made clear whether this statement refers exclusively to the species-level, where, in the Dutch system, morphological distinctions are admittedly of less significance than physiological; but in any event it accords with the author's previous contention¹ that "the important thing about yeasts is their biochemical behaviour". This point of view, which appears to be common in contemporary biology, is not shared by us.

The proposal to classify yeasts by means of biochemical distinctions is evidently based on the belief that other biological criteria are, if not trivial, merely expressions of the physicochemical nature of the cell, in particular its constituent enzymes, proteins and nucleic acids, and are therefore redundant.

Barnett proposes tests which are designed to determine the enzyme content of any particular yeast in the hope that each test will reveal the presence or absence of a single enzyme. The diagnostic value of this type of investigation is indisputable since possible groupings could be envisaged from data which showed, let us say, that enzyme X occurs in only 25 per cent of the yeasts, or that of the 20 enzymes known to be regularly present in yeast A, 17 are common to yeast B, while only 8 are found in yeast C and 6 in yeast D. But here two questions can reasonably be asked: (1) Are such classifications supposed to reveal phylogenetic relationships, or are they primarily intended as artificial practical groupings? (2) Is a yeast cell to be regarded as nothing more than an assemblage of enzymes?

With respect to the first question, it is not clear what Barnett expects his new system of classification to reveal, apart from the presence or absence of specific enzymes and an improved understanding of the biochemical processes in which they participate. These *per se* constitute an admirable objective, though, with reference to classification, one to which the epithet 'stable' scarcely applies. The primary concern of any new microbial classification deserving of the name should be an attempt to demonstrate the natural relationships of the organisms involved. Otherwise it is mere cataloguing and devoid of intrinsic biological interest. In the absence of a fossil record of the yeast fungi, can one expect their natural relationships to be disclosed solely by a knowledge of the enzymes contained in their cells, even if this were extended to include studies of enzymatic organization and metabolic pathways? We think not. While biochemical processes are the basis of life, they are not synonymous with it, and to ignore life's outward manifestations, however subjective they may be, can only lead to an imperfect conception of the taxonomic whole: no one, in attempting to distinguish between a lion and a tiger, would ignore morphological criteria in favour of enzymatic. Although all schemes of microbial classification naturally embody a strong subjective element, certainly the truest and most satisfying picture will be derived from a synthesis and integration of all available knowledge. In the words of Pirie⁵, "many different types of information can be, and should be, woven into the classificatory scheme, and there is no obvious advantage in attaching overriding importance to any one type".

As for the yeasts—that motley assemblage of micro-organisms defying definition—are we really asked to consider them as nothing more than bags of enzymes? For those who have devoted consider-

able time to observing through the microscope the multitudinous and variegated forms which these organisms assume and the beauty and elegance of their structures, it is almost an affront to be told that such observations are to be avoided because of their imprecision and subjectivity. It is not irrelevant to stress that hitherto one of the basic driving forces of the natural scientist has been his aesthetic appreciation of and affection for his subject-matter; the extinction of this attitude is likely to do no good to science in particular or to culture in general. It is understandable that the spirit of disinterested inquiry should lead man behind the outward forms of life in his search for its physical and chemical basis, but to ignore wilfully, in this unremitting itch for abstraction, that which can be perceived directly and appreciated aesthetically can never be biologically sound. It is quite true, as Barnett points out, that the factors influencing sporulation in yeasts are ill-understood, and that when a yeast will not sporulate under laboratory conditions this is no proof that it is incapable of doing so. But from this it does not logically follow that one need not search for spores. Sporulation in the ascosporogenous yeasts is indicative of sexuality, reproduction, recombination and maintenance of the species, and is a manifestation of life and evolution. For our part, we shall continue to search for it.

Through years of patient observation under the leadership of Kluyver, the Dutch school of yeast taxonomy created order out of chaos, and in spite of methodological shortcomings and imperfect knowledge, it was a magnificent attempt. As it stands to-day, it is primarily a practical system which most probably permits only faint and vague glimpses of the true phylogenetic relationships of the yeasts; but because it is based on a sound biological approach including morphology, sporulation, alternation of generations, and physiology, we believe that in the course of time it is destined to be revised rather than superseded. It is likely that such a revision will eventually encompass some of the alternative views of yeast classification⁴⁻⁸, which, however, are themselves neither permanent nor stable, particularly since the evolutionary speculations which they contain are probably premature. But it is certain that besides dealing with the large number of new yeasts recently described, any taxonomic revision must include a more thoroughgoing genetic approach. Herein lie many fundamental problems: the possible elucidation of the species concept⁹, the possible pooling of hereditary characters by means other than sexual reproduction¹⁰, the determination of linkage groups and chromosome number, and the study of mutation and adaptation in their bearing on experimental evolution⁴. In addition to genetic data, more detailed knowledge is needed of the sexual process, of life-cycles, of comparative cytology, of morphological response to changing environmental conditions, of natural habitats and distribution⁷, and certainly of the biochemical activities of these organisms. Here, in particular, the recent findings of instability in certain fermentative characters^{11,12} may have significant taxonomic implications.

It may be expected that patient research in these various fields will gradually elucidate some of the natural relationships existing among the yeast fungi, although a complete picture of their evolutionary history is scarcely attainable. But even partial

taxonomic enlightenment will not be in vain, if it can induce a sense of wonder and humility at the vast diversity of life manifest even in this small group of micro-organisms.

BACTERIOLOGY

Knall-gas Reaction-linked Fixation of Labelled Carbon Dioxide in an Autotrophic *Streptomyces*

THE occurrence of a *Streptomyces* capable of growing autotrophically in the presence of a Knall-gas (oxy-hydrogen) mixture has previously been reported (*St. autotrophicus*, Takamiya and Tubaki¹). The present work was planned to investigate the autotrophic assimilation of labelled carbon dioxide in this organism.

An autotrophic growth of *Streptomyces autotrophicus* was obtained by inoculating an inorganic medium of the following composition with spores or small flakes of fresh growth taken from a culture of the organism grown on an inorganic agar slant. (Composition of the inorganic nutrient medium: 1.22 gm. potassium dihydrogen phosphate, 2.46 gm. crystalline magnesium sulphate, 1.32 gm. ammonium sulphate, 2.8 mgm. crystalline ferrous sulphate, 1 ml. Arnon's micronutrient solution A₁, and 0.84 gm. sodium bicarbonate in 1,000 ml. distilled water (pH 7.0).) The culturing was carried out at 27° C. in an air/hydrogen gas mixture (1:1). After 3-4 weeks, the surface of the culture medium was found to be covered with a snow-white growth of the organism, amounting to 5 mgm. dry weight per 100 cm.² liquid surface. For the purpose of comparison, heterotrophic culturing was also performed, using an organic medium containing peptone (1 per cent; pH 7.0) as the source of carbon and nitrogen. The culture was poured into a separation funnel to float the colonies to the surface of the liquid. The floating colonies were washed with distilled water and with 0.03 M phosphate buffer (pH 7.2), and desired amounts of the organism were collected by loopfuls into a reaction vessel.

The measurement of gas-uptake was performed with a Warburg manometer (27° C.) with hydrogen

Table 1. CARBON DIOXIDE FIXATION COUPLED WITH OXYHYDROGEN REACTION IN *Streptomyces autotrophicus*

Gas atmosphere	Time of reaction (min.)	Radioactivity incorporated (c.p.m./mgm. cell dry weight)			Carbon dioxide fixed (calculated) (μ mol./mgm. cell dry weight)	Hydrogen consumed (μ l./mgm. cell dry weight)
		Insoluble	Soluble	Total		
80 per cent hydrogen + 20 per cent oxygen	10	89	1,168	1,257	0.048	7
80 per cent hydrogen + 20 per cent oxygen	30	272	2,068	2,330	0.089	21
80 per cent hydrogen + 20 per cent oxygen	90	980	4,919	5,899	0.225	56
Air	90	8	138	146		

and nitrogen introduced in the reaction vessel after evacuation of the air. A preliminary investigation revealed a marked consumption of oxyhydrogen gas in the autotrophically grown cells, which was in accord with the equation of a Knall-gas reaction. In a typical experiment, 110 μ l. hydrogen and 66 μ l. oxygen, as determined by the manometric method of Schatz and Bovell², were consumed in 50 min. by 5-mgm. dry weight cells taken from a 90 day-old autotrophic culture (endogenous respiration: 8 μ l. oxygen-uptake). No Knall-gas reaction was detected with heterotrophically grown cells of the same organism.

An isotope experiment was performed to detect the capacity of the organism to fix inorganic carbon. Autotrophically grown cells (80 day-old) were floated on the surface of a 0.03 M phosphate buffer (pH 7.2) placed in the main chamber of a Warburg vessel. The gas atmosphere was a hydrogen/oxygen mixture (4:1) freed from contamination of carbon dioxide. In the course of manometric measurement of oxyhydrogen reaction at 27°C., the solution of labelled carbon ($\text{NaH}^{14}\text{CO}_3$, 4.5 μ moles; 1.18×10^6 c.p.m.) contained in the side-arm of the vessel was introduced into the main chamber. The reaction was stopped by adding 0.5 ml. of an acetic/hydrochloric acid mixture (4:1) after 10, 30 and 90 min. of reaction. Each sample of test organism was extracted and repeatedly washed with ethanol (final concentration, 80 per cent). The soluble fraction was separated from the insoluble cell material by centrifugation; the extract and the insoluble residue were dried in air on metal disks under an infra-red lamp. The results of the radioactivity measurements are presented in Table 1. It will be seen that bicarbonate carbon is readily incorporated by the organism when an oxyhydrogen mixture is present in the gas atmosphere. It must also be noted that the greater portion of the assimilated radiocarbon is discovered in the alcohol-soluble fraction. (Essentially the same results were obtained on stopping the reaction with boiling ethanol (final concentration, 80 per cent), instead of the acid mixture.) The efficiency of carbon assimilation as expressed by the ratio of incorporated carbon to consumed hydrogen and oxygen was as follows:

$$\text{H}_2 : \text{O}_2 : \text{CO}_2 = 10 : 5 : 1$$

In another set of experiments, autotrophically grown cells (120 day-old) were pre-incubated for 70 min. at 27°C. in an oxyhydrogen gas atmosphere (or air in control experiments) freed from carbon dioxide. The gas was then removed by evacuation and flushing with air or pure nitrogen: this procedure was repeated twice. After varied periods of such blank incubation, the organism was supplied with $\text{NaH}^{14}\text{CO}_3$ injected through a rubber stop-cock (fitted in this case instead of the side-arm of Warburg vessel), and further incubated for 10

min. to be tested for the amount of fixed carbon dioxide. All the experimental procedures after the introduction of acid mixture were the same as those described above. From the results presented in Table 2, it will be seen that the capacity for carbon dioxide fixation under the conditions of these experiments remains unabated for some time. Under aerobic conditions in the blank period, however, a significant decrease in fixation capacity occurs, so that after 3 min. in air, the fixation capacity of the test organism was as low as about 30 per cent that of the anaerobic control.

Table 2. CARBON DIOXIDE FIXATION IN *Streptomyces autotrophicus* PRE-INCUBATED WITH OXYHYDROGEN GAS MIXTURE

Pre-incubation (for 70 min.)	Condition of blank incubation after removal of hydrogen gas (min.)	Reaction with $^{14}\text{CO}_2$ (min.)	Total radioactivity incorporated (c.p.m./mgm. cell dry weight)
80 per cent hydrogen + 20 per cent oxygen	in air 0.5	10	513
	in air 3.0	10	319
	in air 10.0	10	219
	in N_2 3.0	10	935
	in $\text{H}_2 + \text{O}_2$ (that is, no gas exchange)	10	1,290
Air	in air (that is, no gas exchange)	10	143

It can be concluded from these results: (1) The autotrophically grown cells of *Streptomyces autotrophicus* are capable of fixing carbon dioxide; (2) The utilization by this organism of the energy derived from the oxyhydrogen reaction is also evident, the endogenous fixation of carbon dioxide in the absence of hydrogen gas being negligibly small. It is also to be noticed (3) that the inducing effect of the oxyhydrogen reaction on carbon dioxide assimilation is retained, for some time, in cells pre-treated with the gas mixture. The occurrence of a Knall-gas reaction-linked fixation of carbon dioxide has repeatedly been observed in the group of hydrogen bacteria²⁻⁶. However, this type of autotrophic carbon assimilation has not yet been reported in the class of actinomycetes. The sluggishness of the process in our test organism, which may also be the

Table 3. KNALL-GAS REACTION-LINKED FIXATION OF CARBON DIOXIDE IN HYDROGENOTROPHIC AUTOTROPHS

Organism	QH_2 (μ l./hr., mgm. cell dry weight)	QCO_2 (μ l./hr., mgm. cell dry weight)	Efficiency $\text{CO}_2 : \text{H}_2$
<i>Hydrogenomonas facilis</i> *	446	72	1 : 6.2
<i>Hydrogenomonas ruhlandii</i> †	204	34	1 : 7.8
<i>Streptomyces autotrophicus</i> ‡	37	3.4	1 : 10.9

‡ Isotopic experiments (present work, see Table 1).

cause of the slowness in its growth, is conspicuous, although the efficiency of the assimilatory process, as expressed by the carbon dioxide/hydrogen ratio, is not inferior. For the purpose of comparison, typical data in this connexion are summarized in Table 3 together with our own results. The slow rate found in the present case may partly originate from the circumstance that we had to use cells taken from old cultures, often several weeks old, in order to secure sufficient amounts of the organism for the test.

We wish to acknowledge here the continuous interest of Prof. H. Tamiya, University of Tokyo, during this work, which was supported in part by a research grant from the Ministry of Education.

Action of 6-Aminopenicillanic Acid on Gram-negative Bacteria

THERE is abundant evidence to support the theory that at least one way in which penicillin exerts its antibacterial effect is to prevent the synthesis, during cell division, of a rigid component of the cell wall. If this action takes place in normal culture medium, the result is lysis; if in a hypertonic environment, the cell changes into a spherical body or spheroplast¹. We have found that the parent amine, 6-aminopenicillanic acid², from which the natural penicillins may be considered to be derived by acylation, induces morphological changes similar to those produced by benzylpenicillin, 6-(α -phenoxypropionamido)penicillanic acid ('Broxil'), and phenoxymethylpenicillin (penicillin V).

In our experiments, 0.15 ml. of a 17-hr. culture of the organism, grown on a rotator at 37° C., was added to 10 ml. of the following medium, containing per litre: sodium chloride 5 gm., 'Lab. Lemco' (Oxoid) 5 gm., peptone 10 gm., sucrose 114 gm., crystalline magnesium sulphate 2.5 gm. The sodium salt of 6-aminopenicillanic acid was added to give the desired final concentration. Examination by interference microscopy after incubation for 4–5 hr. at 37° C. gave the results shown in Table 1.

Table 1. CONCENTRATIONS OF SODIUM BENZYL-PENICILLIN AND SODIUM 6-AMINOPENICILLANATE TO INDUCE SPHEROPLAST FORMATION IN CERTAIN GRAM-NEGATIVE BACTERIA

	Sodium benzylpenicillin (μ mole/ml)	Sodium 6-aminopenicillanate (μ mole/ml)
<i>E. coli</i> (formerly N.C.T.C. 5934)	0.167	0.68–1.7
<i>Cloaca cloacae</i> (N.C.T.C. 8155)	0.167	0.34
<i>E. coli</i> (K12)	1.67	3.4
<i>Ps. pyocyanea</i> (N.C.T.C. 7244)	0.42	0.84
<i>Serratia marcescens</i>	1.67	1.7–3.4
<i>Proteus vulgaris</i> (N.C.T.C. 7052)	1.67	1.7–3.4

It can be seen that sodium 6-aminopenicillanate in concentrations approximately twice those of sodium benzylpenicillin induced spheroplast formation. In lower concentrations, bizarre morphological variants were obtained. The spheroplasts underwent lysis on dilution of the medium with water.

Batchelor *et al.*³ report that 6-aminopenicillanic acid possesses definite antibacterial properties, but of a much lower order than benzylpenicillin. It would appear that the presence of the acyl side-chain on the primary amine is not essential for spheroplast formation. Quantitative differences may be due to factors involving access to the site of action.

We thank Drs. J. Farquharson and E. T. Knudsen, of Beecham Research Laboratories, for a generous gift of 6-aminopenicillanic acid and 6-(α -phenoxypropionamido)penicillanic acid.

VIROLOGY

Serological Detection of a Virus in Cherry Trees with a Leaf Roll Disease

LEAF roll virus disease of sweet cherry (*Prunus avium*)^{1,2} has been identified (by graft-transmission to indicator plants) in eight orchards in Kent and one in Worcestershire. Six of these outbreaks have been investigated further, and in each of them the same virus was isolated from infected trees. When buds or young leaves were macerated in 0.05 M phosphate buffer (pH 7.8) or 0.01 M sodium diethyl-dithiocarbamate solutions and rubbed on to the leaves of young herbaceous plants, chlorotic and necrotic spots, rings and lines developed on the leaves of tobacco (var. White Burley), while *Chenopodium amaranticolor* plants were stunted, with mottled and distorted leaves. The virus was also transmitted by sap inoculation from tobacco to *Prunus avium* and *P. pennsylvanica* seedlings, and from *Prunus avium* to *P. pennsylvanica*.

An antiserum was prepared by intravenous injections into a rabbit of virus preparations precipitated from the infective tobacco sap by ammonium sulphate.

Precipitation tests were made in a gel containing 0.7 per cent 'Ionagar' No. 2, 0.9 per cent sodium chloride and 0.02 per cent sodium azide. This medium was run into Petri dishes to a thickness of 3 mm., and holes cut in the gel with a small cork borer to receive diluted antiserum or antigen. Single precipitation lines formed between holes filled with antiserum and those with undiluted sap from *Chenopodium* plants infected with this virus. No precipitation lines formed with sap from healthy *Chenopodium* plants or from plants infected with *Arabis* mosaic and tomato black ring viruses.

Specific precipitation lines were formed when sap from buds or young leaves from infected cherry trees was used as the antigen; the sap was antigenic

when diluted 1:2 with water, phosphate buffer or sodium diethyl-dithiocarbamate and also when undiluted. No precipitation lines formed with similar preparations from trees infected with *Arabis* mosaic, raspberry ringspot, necrotic ringspot, little cherry, ring mottle and rusty mottle viruses.

There is no previous record of the transmission of a virus within or between species of *Prunus* by sap inoculation, and none has proved antigenic in cherry sap except necrotic ring spot and sour cherry yellows, which need to be purified and concentrated before they can be detected serologically².

A Lipid Component of Murray Valley Encephalitis Virus

FOLLOWING the early work of Taylor *et al.*¹, it is generally believed that the arthropod-borne viruses contain ribonucleic acid, protein and lipid. Recent work has shown that the ribonucleic acid fraction extracted by phenol from several viruses of this group is infective². In the intact virus the protein fraction probably protects this ribonucleic acid and may have other functions. The present report considers a lipid component of the virus of Murray Valley encephalitis virus, and shows that this virus is inactivated by phospholipase A.

Crude virus was prepared as a 20 per cent baby mouse brain extract and purified virus was prepared from such a suspension³. Standard infective ribonucleic acid was prepared by treating crude virus with phenol⁴. Virus and ribonucleic acid were titrated on the chorioallantoic membrane of chick embryos⁴. Phospholipase A, supplied to us by Miss H. Doery of the Commonwealth Serum Laboratories, had been purified from the venom of the black snake (*Pseudechis porphyriacus*) (Doery, H. M., and Pearson, S. E., to be published). To ensure that so far as possible the only functional enzyme in the preparation was phospholipase A, each sample was boiled for 10 min. in physiological saline (pH 6.0) before being used.

Equal volumes of undiluted virus and phospholipase diluted in physiological saline were mixed and held at 37° C. for 30 min. The remaining infective virus was titrated. Both crude and purified viruses were rapidly inactivated by 100 µgm./ml. of phospholipase A (Table 1). The inactivated virus preparations were then treated with phenol to liberate infective ribonucleic acid. The yield of ribonucleic acid was always higher than the titre of virus, a result which

indicated that phospholipase A acted on some component of the virus other than the ribonucleic acid.

Titration of the enzyme was attempted by using serial dilutions of enzyme in the above system, and defining the end-point as that concentration of enzyme which reduced the infectivity of undiluted virus by 2 logs. The end-point against crude virus was consistently at 0.05 µgm./ml. of enzyme. The end-point against purified virus varied from 2.0 to 0.1 µgm./ml. in 10 experiments: this wide variation was thought to be related to the varying lability of purified virus at 37° C., even in the absence of phospholipase A.

Standard infective ribonucleic acid prepared from crude virus was much less susceptible to phospholipase A than was virus, the end-point of the enzymic action against ribonucleic acid being at 100 µgm./ml. The high concentration suggested that the action was due to a contaminant and not to the phospholipase A. For example, the presence in the phospholipase preparation of 7 parts per million of a nuclease similar to pancreatic ribonuclease could explain the result⁴.

From the above results, it was concluded that Murray Valley encephalitis virus was inactivated by the cleavage of fatty acid(s) from phospholipid(s) contained in its structure. It was unlikely that infective ribonucleic acid contained lipid as a vital component.

Purified influenza virus is known to contain large amounts of phospholipid. Influenza virus strain WSE was purified from infected allantoic fluid⁵, and treated with phospholipase A (1,000 µgm./ml., 37° C., 30 min.) both with and without added normal baby mouse brain extract. Virus infectivity, as titrated in the allantoic cavity of chick embryos, was not reduced by this treatment. The failure of phospholipase A to inactivate influenza virus might mean either that intact phospholipid was not necessary for infectivity, or that the phospholipid was not accessible to the action of the enzyme.

Two interpretations of the results with Murray Valley encephalitis virus seem to be possible. The most direct hypothesis is that viral phospholipid has a specific function during infection of the chorioallantoic membrane. For example, it might assist in the absorption of virus to host cell, or might allow the virus particle to react with some intracellular system. A second possibility is that the phospholipid is not functional in this sense. It might be largely host cell lipid incorporated during intracellular growth or emergence of virus from the host cell; or it might be synthesized under the influence of the viral genome. In any event it will contribute to viral structure. On this view the alteration of phospholipid in a mature Murray Valley encephalitis virus particle might so distort the viral architecture as to render the particle non-infective.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, December 5

INSTITUTE OF METAL FINISHING (at the Café Royal, Regent Street, London, W.1), at 2.30 p.m.—Annual General Meeting, followed by Prof. J. W. Cuthbertson: "A Metallurgist's Thoughts on Electrodeposition" (Hothersall Memorial Lecture).

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. G. Buchdahl: "Model, Symbol and Fact".

UNIVERSITY COLLEGE (in the Physiology Theatre, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. W. Feldberg, F.R.S.: "Mediators of Allergic Reactions".*

UNIVERSITY OF LONDON (in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. John O. Corliss (University of Illinois): "Phylogeny and Evolution of the Ciliated Protozoa—Application to Systematics".* (Last of three lectures on "The Evolution of the Protozoa".)

Tuesday, December 6

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. D. O. Heinrich: "Study on Electro-Preseparator Performance in Relation to Particle Size Distribution, Level of Collection Efficiency, and Power Input".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. D. Gabor, F.R.S., Dr. W. P. L. Wilby and Dr. R. Woodcock: "A Universal Non-Linear Filter, Predictor and Simulator, which Optimizes Itself by a Learning Process".

RESEARCH DEFENCE SOCIETY (in the Physiology Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. J. H. Burn, F.R.S.: "Testing Drugs on Man" (Twenty-ninth Stephen Paget Memorial Lecture).

UNIVERSITY OF LONDON (at the Imperial College of Science and Technology, London, S.W.7), at 5.30 p.m.—Prof. H. Elliot: "Cosmic Rays and the Exploration of Space" (Inaugural Lecture).

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. D. G. Catcheside: "Functional Structure of Genes".* (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

ROYAL AERONAUTICAL SOCIETY, ASTRONAUTICS AND GUIDED FLIGHT SECTION (at 4 Hamilton Place, London, W.1), at 6 p.m.—Dr. G. H. S. Young: "Solid Propellant Rocket Motors".

OIL AND COLOUR CHEMISTS' ASSOCIATION (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Mr. G. Phillips and Mr. P. Walker: "Newer Methods of Testing Paint Film".

BRITAIN CHINA FRIENDSHIP ASSOCIATION, HAMPSHIRE BRANCH (at Hampstead Town Hall, Haverstock Hill, London, N.W.3), at 7.45 p.m.—Dr. Joseph Needham, F.R.S.: "China and the Development of World Science".

Wednesday, December 7

UNIVERSITY OF LONDON (at the Postgraduate Medical School of London, Ducane Road, London, W.12), at 2 p.m.—Dr. A. E. Kellie: "Steroid Assays".*

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5 p.m.—Mr. A. J. Miller: "A Queueing Model for Road Traffic Flow"; Mr. J. C. Tanner: "Delays on a Two-Lane Road".

INSTITUTE OF FUEL (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 5.30 p.m.—Mr. P. A. Alexander, Mr. R. S. Fielder, Mr. P. J. Jackson, Mr. R. Raask and Mr. T. B. Williams: "Acid Deposition in Oil-fired Boilers, Comparative Trials of Additives and Testing Techniques".*

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. M. B. Hubbard: "The Changing Energy Pattern in Europe and its Possible Effect on Product-Mix".

SIR THOMAS MIDDLETON MEMORIAL TRUST (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. J. D. Findlay: "Cattle and Climate" (Eighth Memorial Lecture).

BRITISH INSTITUTION OF RADIO ENGINEERS, RADAR GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. H. G. Hinesley: "Flight Evaluation of Airborne Electronic Equipment".

SOCIETY FOR ANALYTICAL CHEMISTRY (in the Main Chemistry Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Discussion Meeting on "The Flask Combustion Technique".

BRITISH PSYCHOLOGICAL SOCIETY, SOCIAL PSYCHOLOGY SECTION (in Room 411, Birkbeck College, Malet Street, London, W.C.1), at 8 p.m.—Prof. Fritz Heider: "On Person Perception".

Wednesday, December 7—Friday, December 9

SCIENTIFIC AND TECHNICAL GROUP OF THE ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (in the Lecture Theatre of the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2)—Conference on "The Ultimate Sensitivity in Photography—To-day and To-morrow".

Thursday, December 8

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Bryan Matthews, F.R.S., and Mr. T. C. D. Whitehead: "Tendon Reflexes in Free Fall"; Mr. Q. Bone: "The Organization of the Atrial Nervous System of *Amphioxus* (*Branchiostoma*)".

INSTITUTION OF ELECTRICAL ENGINEERS, UTILIZATION SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. J. Ravenscroft: "The Determination of the Electrical Characteristics of an Arc Furnace".

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. E. J. L. Lowbury: "Drug Resistance and the Response to Chemotherapy". (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Sir Selby Zuckerman, F.R.S.: "The Social Function of Science—1960" (Rickman Godlee Lecture).*

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 7 p.m.—Prof. M. Stacey, F.R.S.: "Aromatic Fluorine Compounds".

CHEMICAL SOCIETY (in the Lecture Theatre, The Royal Institution, Albemarle Street, London, W.1), at 7.30 p.m.—Prof. R. Huisgen: "1,3-Dipolar Cycloadditions" (Centenary Lecture).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Symposium on "Hookworm Diseases". Contributors: Dr. S. Stott, Dr. E. van Oye and Dr. Henry Foy.

Friday, December 9

ASSOCIATION OF APPLIED BIOLOGISTS (at the Royal Entomological Society, 41 Queen's Gate, London, S.W.7), at 10.15 a.m.—Paper Reading Meeting.

BRITISH PSYCHOLOGICAL SOCIETY, OCCUPATIONAL PSYCHOLOGY SECTION (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mr. John Spencer: "Thoughts about Automation".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. R. L. F. Boyd: "Rocket Astronomy".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

POSTGRADUATE STUDENT (recent graduate with a good degree in physics or physical chemistry) IN THE DEPARTMENT OF PHYSICS, to research under the supervision of Dr. J. G. Powles on some aspects of magnetic resonance—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (December 9).

RESEARCH ASSISTANT (graduate biochemist or biologist with training in chemistry) IN THE ZOOLOGY DEPARTMENT, to assist in research in tank culture or bivalve shellfish—The Registrar, The University, Southampton (December 10).

TUTORIAL STUDENT IN THE DEPARTMENT OF BIOCHEMISTRY—The Registrar, King's College (University of London), Strand, London, W.C.2 (December 12).

SCIENTIFIC OFFICER, Grade 1 (with an honours degree in physics, mathematics or electrical engineering, and preferably some postgraduate experience in ionospheric research) AT THE WEAPONS RESEARCH ESTABLISHMENT, Salisbury, near Adelaide, Australia, to engage in research and development work in the field of ionospheric physics—The Senior Representative (A.V.91/6), Department of Supply, Australia House, Strand, London, W.C.2 (December 15).

SCIENTIFIC OFFICER, Grade 1 (with an honours degree in physics, and preferably some research experience) AT THE WEAPONS RESEARCH ESTABLISHMENT, Salisbury, near Adelaide, Australia, for research and development in physics, mainly in the field of solid state and infra-red physics—The Senior Representative (A.V.89/6), Department of Supply, Australia House, Strand, London, W.C.2 (December 15).

FELLOW OR SENIOR FELLOW IN PHILOSOPHY within the Department of Social Philosophy, Institute of Advanced Studies, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, December 30).

SENIOR LECTURER/LECTURER IN SCIENTIFIC THOUGHT in the School of Philosophy, University of New South Wales, Kensington, N.S.W., Australia—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (Australia and London, December 30).

POST-DOCTORAL RESEARCH FELLOW IN PHYSICAL CHEMISTRY, to study properties of solids by mass spectrometry—The Registrar, The University, Edgbaston, Birmingham 15 (December 31).

READER-IN-CHARGE (with a special knowledge of the physical and dynamic aspects of the subject) OF METEOROLOGY at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, December 31).

CHAIR OF THEORETICAL PHYSICS at Birkbeck College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 5).

LECTURERS (2) IN CHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 6).

CHAIR OF CIVIL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (January 14).

JAMES WATT CHAIR OF ELECTRICAL ENGINEERING—The Secretary of University Court, The University, Glasgow (January 14).

POSTGRADUATE RESEARCH FELLOW IN THE DEPARTMENT OF BOTANY, for the study of micro-organisms involved in cellulose decomposition—Prof. C. J. Hickman, Department of Botany, University of Western Ontario, London, Ontario, Canada (February 28).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS IN CHEMISTRY, PHYSICS, METALLURGY, ENGINEERING, GEOLOGY, AGRICULTURAL SCIENCE and related subjects—The Registrar of the University of Wales, University Registry, Cathays Park, Cardiff (March 6).

ASSOCIATE PROFESSOR OF CLINICAL PSYCHOLOGY—Prof. F. Hilton Page, Head of the Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada.

DEMONSTRATOR/LECTURER (with a degree in physics or general science) IN THE DEPARTMENT OF PHYSICS, Middle East Technical University, Ankara—Room 139, Foreign Office, London, S.W.1.

PHYSICIST, CHEMICAL or MECHANICAL ENGINEER, Scientific/Senior Scientific Officer grade (with a first- or second-class honours degree in physics, chemical or mechanical engineering), at the Fire Research Station (D.S.I.R.), Elstree, Herts, to join a group studying the growth and spread of fire—Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.484/0A.

POSTDOCTORATE FELLOW (suitably qualified candidate interested in theoretical calculations of the hydrogen bond energy between water molecules and the energy of ice as a function of hydrogen orientation)—Dr. R. S. Campbell, Department of Chemistry, New York University, New York 53, N.Y., U.S.A.

SENIOR LECTURER (with an honours degree and suitable teaching and research experience, and preferably a higher degree and specialization in modern and atomic physics) IN PHYSICS—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Witham, Essex, London, E.17.

SENIOR LECTURER (with qualifications and experience to teach mathematics for the Diploma of Technology courses and for degree courses in engineering and science) IN MATHEMATICS—The Registrar, Bradford Institute of Technology, Bradford 7.

INTERNATIONAL CO-OPERATION IN RESEARCH

IN an address at the opening of the new Physics Building of the Imperial College of Science and Technology on October 20, Sir John Cockcroft referred to the growing complexity of equipment required for physical and chemical research, and consequent mounting of costs during the past three decades. The scale of expenditure on physics has doubled and redoubled, partly from the feed-back from technology, which is providing ever more powerful and discerning tools, and partly from the frequent combination of several different disciplines to attack new problems. Sir John instanced the combined British Universities liquid hydrogen bubble chamber project, and Prof. McGee's work on an electronic device to convert beams or radiation from stellar and other sources into electrical currents, from which was expected to come a 120-in. telescope as powerful in most respects as the 200-in. giant of Mount Palomar. With the use of modern tools, chemistry departments already have operating costs comparable in scale with those of the Cavendish Laboratory.

Sir John said Britain is inevitably left far behind by the Americans and Russians in the immensely expensive projects of space science and space travel, although Sir Harrie Massey is playing a leading part in the almost uncharted field of space research. Britain is still holding her own in most basic fields of science. Britain started with the advantage of a good flow of first-class young scientists from the universities. An increasing amount of support also came through the Research Grants Committee of the Department of Scientific and Industrial Research and the other Research Councils. During Prof. Blackett's tenure of the chair of the Research Grants Committee, funds for the support of basic science in the universities had increased five-fold, and are now more than double those for major items of equipment coming through the University Grants Committee.

Nevertheless, at a College of Science and Technology of which Sir John is vice-president, only some £500 per research worker is available from the University Grants Committee and College funds for all departmental supplies, though this is increased by about 80 per cent by contributions from outside bodies, including the United States Army; 20 per cent of this external support comes from the Department of Scientific and Industrial Research. Sir John thought that this pattern is characteristic of many university institutions, and while he suggested that diverse channels of support for science would always be a safeguard and assist its growth, he believes that in strengthening Britain's science and technology it is more important to strengthen them in the universities than anywhere else at the present time.

As regards the growing scale of science in the next five years or so, he emphasized that to take full advantage of the present great opportunities the universities in Britain need several computers one hundred times faster than those now available to them. These would cost one or two million pounds apiece, but, thanks to the so far unrequited initiative of British industry, could be available from home sources if there was no long delay. Radio astronomers also need increased support to maintain their outstanding position in this new field of science and, apart from the increasing demands of theoretical astronomy, there are the claims of space research. Sir John did not attempt to discuss how far we would be justified in entering this field for the sake of developments in future technologies, but pointed out that present technologies are still far from adequately supported. The great potentialities for scientific and technological development in the universities of Britain could be exploited much more fully and with great benefit to the country if we increased the funds available to them for research equipment, technicians and urgently needed laboratories by only 1 per cent of the total sum now spent on research and development.

In this address on the strengthening of science in Britain, Sir John Cockcroft thus far largely followed the argument of the latest report from the Advisory Council for Scientific Policy. Like the Advisory Council, he recognizes, too, that the general growth in the scale of equipment and the costliness of science is leading to some evolution of the organization of science. While, however, he noted that we have already found it necessary to build the largest accelerators in the National Institute for Nuclear Science, where ten universities are already experimenting with the first of the accelerators to be built, the future relation of such national institutes to the central Government has still to be worked out. The first National Institute has made a good start and can, Sir John believes, be taken as a pattern for other collaborative university activities, such as space research and astronomy, though, to facilitate collaboration, the difficulties of working away from a university base require easing, and universities must recognize research work carried out at the National Institute for higher degrees.

Sir John also referred to the desirability of powerful research tools in Government establishments, such as the 20-MV. research reactors at Harwell and the powerful computers of the Atomic Energy Authority, being available so far as possible to university research workers. Comparatively modest expenditure on travel and equipment for university workers could do much to make this possible, but he also thought that co-operation should include a greater

participation in university teaching by the staffs of Government establishments than is at present the practice. Moreover, if and when other Government technological establishments are being founded, there is much to be said for building them on the campus of a university (as is the case in Australia), provided that by then the embarrassing differences of salary-level have disappeared.

Sir John did not pursue that issue; nor did he follow up the implications of his comment that in many fields the cost of technological research is of the order of £7,000 per annum per research worker, and that the universities are making nothing like the contribution to the advancement of technology that they do to the advancement of science. He was content to point to the great opportunities and to stress the need for more inter-disciplinary projects. There are, indeed, in some Government establishments and in some Medical Research Council units, such as the Molecular Biology Research Unit at Cambridge, teams of mathematicians, engineers, physicists, physiologists and others, but more of this is needed in the universities in the future.

Perhaps the most important of Sir John's suggestions for the strengthening of science lie in the field of international co-operation. Referring to the building of the high-energy proton synchrotron at Geneva, in which Britain has joined forces with eleven other European nations, he said that a far better team had been collected than could have been obtained in Britain, and the combined technical resources of the member countries greatly exceeds those of any single country. As in the similar co-operative project to build the *Dragon* reactor at Winfrith Heath, British leadership has played a decisive part, and he believes that similar international co-operation is desirable for other large-scale projects such as a future radio telescope, which might cost ten times as much as that at Jodrell Bank, or for the large optical telescope for the southern hemisphere now being discussed.

Such international co-operation is the major theme of a report, to which Sir John Cockcroft referred, on increasing the effectiveness of Western science, prepared by a study group of the Science Committee of the North Atlantic Treaty Organization, and also sponsored by the Ford Foundation*. This report begins by stressing the importance of increasing the effectiveness of Western science, both from the point of view of security and from that of raising the standard of living in the Western countries, quite apart from the dominant part which science holds in our twentieth-century civilization and its challenge and inspiration to the spirit of men. Indeed, the report urges not simply a conscious effort to devote adequate resources to science, but also pleads for a greater unity, for much more interpenetration among the nations until national labels are no longer attached to fields of science. Incidentally, the report appears to accept 2 per cent as about the right proportion

of the gross national product to be devoted to research and development, and some 10 per cent of this, as in the United Kingdom and the United States, to fundamental research.

What the report notes of obstacles to the advance of science is largely common knowledge. Shortage of funds, of buildings, of qualified science teachers, of trained technicians and craftsmen, administrative difficulties, and the traditional structure of universities, are common experience in varying degrees in the Western world, but there are also artificial international obstacles to be removed such as restrictions on visas, inadequate budgets for international travel, customs or currency barriers to the acquisition or replacement of essential equipment, and sometimes restrictions on the tenure of permanent university posts to nationals of that country. Some of these barriers can obviously be removed by national action, as the report does not hesitate to indicate; and the temper favourable to the removal of barriers by national action may well be a pre-requisite to the international action on which the report lays its main stress.

Some of the suggestions are familiar, and the report merely adds its authority to proposals already advanced. Among these are the encouragement by international agencies, in close co-operation with national agencies, of the exchange and employment of scientists between nations. Again, it is suggested that the International Council of Scientific Unions, in collaboration with the International Federation for Documentation and the United Nations Educational, Scientific and Cultural Organization, should be asked to do everything possible to improve documentation. To this end certain specific suggestions are made, such as organization of collaboration between editors of the chief scientific periodicals to ensure uniformity in publication practices; affiliation of the principal documentation centres; evolution of a single international system of indexing; arrangements for providing authors' abstracts; encouragement of additional reviews of broad scientific fields but discouragement of the proliferation of scientific periodicals; and reduction of airmail tariffs for transmitting single copies of scientific publications to libraries and scientific associations. It is also suggested that international funds should be available to assist the technically less-developed nations, especially in the North Atlantic Treaty Organization, to promote science and engineering on the national level, on condition that such funds are used to mobilize national funds for this purpose.

More novel is the proposal to create an international clearing house to expedite the transfer of research equipment, the value of which has already been demonstrated by the Training Centre for Experimental Aerodynamics in Belgium. But the most significant proposal is probably that noted by Sir John Cockcroft—the founding of an International Institute of Science and Technology. Research and educational centres serving the needs of two or more countries are regarded as of particular importance at

* Increasing the Effectiveness of Western Science. (Fondation Universitaire, 11 rue d'Egmont, Bruxelles, 5.)

the present time, and the report instances oceanography, meteorology, the ecological effects of pesticides and pollution, and the science of materials and space science as fields in which such centres could well be distributed among different nations and preferably attached to universities. The recent report of the Advisory Council for Scientific Policy shows that, to some extent at any rate, the Advisory Council already recognizes the importance of international collaboration in such fields; but Sir John Cockcroft goes further, and puts the weight of his authority behind the alternative proposal that one or more such centres could form part of an International Centre of Science and Technology or an Atlantic or European University. He maintains that the only chance of such a project coming to fruition is for Britain to take the lead and build such an Atlantic Institute here, as part of the university expansion programme of Britain, but with powerful help from Western Europe.

The Advisory Council for Scientific Policy's last report is calculated to stimulate some fresh thinking about university co-operation, and apart from all considerations of international co-operation, collaboration between universities must clearly play an increasing part if we are to make the most effective use of our own natural resources for research. These possibilities must obviously be considered by the University Grants Committee, which should also note the suggestions advanced in the NATO report, and even examine them further in their British context without waiting for the consideration of the proposal by an appropriate study group which is recommended. Meanwhile, Sir John Cockcroft's address should help to focus attention at a high level on an aspect of scientific and technological development—no less than of university expansion—which has urgent claims for consideration by the Minister for Science, as well as by the Advisory Council for Scientific Policy and the University Grants Committee.

ROSSBY POSTHUMOUSLY HONOURED

The Atmosphere and the Sea in Motion
Scientific Contributions to the Rossby Memorial Volume. Edited by Bert Bolin. Pp. 509. (New York: The Rockefeller Institute Press; London: Oxford University Press, 1959.) 105s. net.

PROF. C.-G. ROSSBY, a 'life force' in meteorology and oceanography from the late 'thirties until his sudden and untimely death in 1957 at the age of fifty-eight, was to have been honoured by his colleagues and former students with a special volume of papers to commemorate his sixtieth birthday. Those papers, with some notable additions, have now been published, but as a memorial to him.

Rossby's last complete paper was a retrospect and prospect entitled "Aktuella Meteorologiska Problem",

given to the National Science Research Council of Sweden in 1956. This paper, translated, happily appears first in the present volume under the title "Current Problems in Meteorology". In its fifty pages, Rossby covers in masterly fashion all the major meteorological interests of his career, showing us the way his mind moved, and what he and some others sought to achieve in their approach to a science which has so resisted but now and again partially capitulated to the attack of great minds. No other paper of Rossby so exposes, to my mind, the man and the scientist—so much greater he seemed than the sum of his parts.

The other "additions" to the volume are two biographical sketches, one by Prof. Bergeron on the young Rossby, the other by Prof. Byers on Rossby the organizer; followed by a complete Rossby bibliography. Bergeron's study is particularly interesting, revealing to us the Rossby that very few knew except, as it were, by extrapolation—restless, receptive yet highly speculative, anxious to break new trails and become his own master. One sees in part why Rossby took longer than most of his stature to express himself as scientist.

The major part of the volume, the original papers, is arranged in five sections, under headings "The Sea in Motion", "Distribution of Matter in the Sea and Atmosphere", "Characteristic Features of Atmospheric Motion", and "Weather Forecasting". One cannot pass all the papers in review but a few are appropriately mentioned for their relation to some of Rossby's work.

In the early 'forties Rossby realized, by that physical intuition which was so strong in him, that the evolution of the large-scale flow-field of the atmosphere is not much affected, in the immediate sense, by its thermal field. (Ultimately, of course, practically all air motion derives from the thermal field.) As one contributor puts it, "Rossby . . . recognized at a very early date that this must be true and he felt no need for a mathematical proof of this principle". It was his great gift to meteorology that the evolution takes place very nearly under conservation of the absolute vertical vorticity of the air, and by this simplification he greatly encouraged the early introduction of numerical forecasting to practical meteorology. But intuition has to be followed by consolidation and there are two lengthy papers here in which the necessity of Rossby's principle is more or less demonstrated. It is shown that evolutions arising from the large-scale thermal field are generally self-immolating—a result related to recent experience that numerical forecasting, in which the thermal field is included at all stages, gives disappointingly little more success than the simpler Rossby model.

Rossby was always much concerned with the almost discontinuous properties of the atmosphere and oceans—fronts, jet streams and sharp shear lines are just three examples—so that it is very appropriate and highly welcome to find a notable contribution to the theory of fronts in this volume. A. Eliassen argues that the front "is not the asymptotic result of a gradual process (the large-scale horizontal deformation field operating on the field of isotherms) but a catastrophic development" in which wind shear and temperature contrast are formed simultaneously by means of a frictionally induced overturning of air transverse to the isotherms and the release of latent heat in the rising arm. The process is self-maintaining and reversible, and is a development of ideas put

forward earlier by Eliassen himself, and by J. S. Sawyer in the United Kingdom. The same mechanism seems likely to account for the eye of the tropical cyclone.

Finally, one should mention a stimulating essay by Bergeron on the history of ideas in weather analysis and forecasting, with hints on their further development. The author is admittedly depressed by much of the story, of promising lines forsaken and sterile paths pursued, and he finds a major ill in the want of meteorological knowledge of theoreticians (Helmholtz is his first example) and a too-poor mathematical training of 'weather men'. The subject, he says, needs a Maxwell-Hertz in one person and the nearest approximation to have appeared so far was V. and J. Bjerknes, father and son. He pleads for a Lagrangian rather than an Eulerian approach to weather analysis, instancing the success of the Bergen frontal school and of Rossby's Chicago school in this respect, but he recognizes that Lagrangian techniques have not yet been well developed. Perhaps the study of the evolution of the atmosphere will never become an exact science, though the limits of climatic variation suggest that, appropriately formulated, the problem should be soluble. Even in its present formulation there is ample scope for development and Bergeron helps to point the way.

This is a volume of which, one can be sure, Rossby would be proud, a fine example of the growth and stature of the sciences with which it deals and which Rossby spent himself in building. P. A. SHEPPARD

PLANT GEOGRAPHY

Introduction to Plant Geography and Some Related Sciences

By Prof. Nicholas Polunin. Pp. xix+640. (London: Longmans, Green and Co., Ltd., 1960.) 60s. net.

THIS volume is intended to provide "an introduction not only to Plant Geography in the wide sense, but also to much of Plant Ecology and Sociology, to the Plant Kingdom as a whole, and to Economic Botany". Such a task has obvious difficulties, and the subjects make a strange mixture for what is presumably meant to be essentially an introductory text-book on plant geography.

After a preliminary chapter, there follow several dealing with plant classification, physiological reactions, 'adaptations', life-forms, dispersal and migration, and fossil plants. Two chapters deal with foundations of modern distribution and with types and areas of natural distributions. There are then interpolated matters under the headings "Modification and Distribution of Crops (and Weeds)" and "Vital Importance to Mankind". There follow a summary account of environmental factors and an outline of main habitats, successions, and climaxes. Not until more than half-way through the book are the 'vegetational types' dealt with. These are subdivided into those of temperate and adjacent lands, of polar lands and high altitudes, of tropical and adjacent lands, of fresh and inland saline waters, and of seas. The book ends with two chapters entitled "Landscapes and Vegetation" and "Plant Adjustments and Applications", respectively. A great deal of space is occupied by material not immediately relevant to plant geography. As one consequence of this, many of the important phytogeographical subdivisions of the world are very inadequately con-

sidered. Another criticism concerns the sequence of the chapters. Thus, polar lands are dealt with between those with temperate and those with tropical climates.

On the other hand, it must be fairly stated that on the whole the descriptive statements are accurate so far as they go. Controversial matters, such as transoceanic dispersal, continental drift, and nunataks are outlined with the various points of view given without bias. The account of the vegetation of polar lands is a good résumé; but other areas, such as the Mediterranean region, are inadequately treated. The inclusion of a chapter on marine vegetation is commendable.

The fount and format are excellent, and there is a good index. A coloured map has the caption "Generalized Land Vegetation Map of the World" and was prepared by A. W. Küchler (1958) with northern forest and arctic limits by N. Polunin. This map is in parts difficult to interpret and appears to have little connexion with the text. There are 184 figures, the majority from photographs, and many of these are clear and relevant to the text. Bibliographical references are given at the ends of chapters, but these are mostly to books and not to original papers.

W. B. TURBELL

A TRILOGY OF VIROLOGY

The Viruses

Biochemical, Biological, and Biophysical Properties. Edited by F. M. Burnet and W. M. Stanley. Vol. 1: General Virology. Pp. xvii+609. 16.50 dollars; 118s. Vol. 2: Plant and Bacterial Viruses. Pp. xvi+408. 13 dollars. Vol. 3: Animal Viruses. Pp. xvii+428. 12 dollars. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1959.)

VIRUS research originated in pathology, and for more than half the nearly 70 years during which the existence of viruses has been recognized their study was an activity almost confined to pathologists, but the 34 articles that make up these three volumes carry few signs of this. The sub-title, "Biochemical, Biological and Biophysical Properties", makes it obvious that this would be no place to seek such mundane things as clinical descriptions or methods of controlling virus diseases, but it is unexpected that pathogenicity should be so neglected; no article is devoted specifically to it and fewer than 1 per cent of the nearly 1,500 pages even mention it. Yet pathogenicity is not only what makes viruses economically important, but is also the feature that usually first brings their existence to notice and that provides the means for their detection and assay in most kinds of work. If their biochemical and biological properties do not determine the many and varied ways in which viruses interfere with the normal functioning of host cells, what does? It is true that the ability to infect and multiply, rather than to cause disease, is the prime feature of a virus and the one with the greatest significance to biology in general; the emphasis given to this feature is therefore understandable, but it does not justify excluding other abilities rich in scientific interest and unsolved problems. Indeed, the replication of nucleic acid and its relation to protein synthesis already looms so large in virus research that such exclusions can only lead to the subject becoming increasingly unbalanced by attracting a still greater

proportion of workers to this currently fashionable line.

The major adverse criticisms to be brought against this trilogy stem from sins of omission, perhaps because the title and sub-title seem to promise too much. "The Viruses" suggests a completeness that is far from fulfilled, for most of the known viruses are not even mentioned. Markham's admirable survey of the properties of plant viruses is exceptional in dealing in some detail with as many as 10 viruses, but most articles are concerned only with tobacco mosaic virus, with T2-coliphage, or with one or other of three animal viruses. Wildman's article, for example, though called "The Process of Infection and Virus Synthesis with Tobacco Mosaic and Other Plant Viruses", in fact mentions only one other virus, and this in only two sentences, one in a footnote. Similarly, although Fraenkel-Conrat's article entitled "The Chemical Basis of the Infectivity of Tobacco Mosaic Virus and Other Plant Viruses" does contain a table showing the sizes and shapes of ten plant viruses, the text mentions only one other than tobacco mosaic virus, and this one gets less space than the two brief paragraphs devoted to animal viruses and bacteriophages.

"Chemical, Physical and Genetical Properties of a Few Viruses" would more accurately reflect the contents of the three volumes, but does not, any more than the existing title, show that nearly 300 pages of Volume 1 are not specifically concerned with viruses. These pages are no less valuable because of this. Indeed, Cohen's scholarly article of 189 pages, plus about 1,000 references, on "Structural and Chemical Architecture of Host Cells with Special Reference to the Synthesis of Polymers" will not only tell most virus workers much more than they previously knew about what goes on in cells, but will also do so for workers in many other subjects. Similarly, the excellent critical discussion of methods used to measure particle sizes that fills 80 of the 100-page article by Schachman and Williams, called "The Physical Properties of Infective Particles", applies to macro-molecules in general.

There is no space here to give the titles of all the articles, let alone comment on them. All that can be done is to list the contributors not already named to show that all are well qualified to write with authority. They are, in order of first appearance, F. M. Burnet, W. M. Stanley, C. E. Schwerdt, S. Gard, O. Maaløe, E. A. Evans, W. Schafer, G. H. Bergold, S. E. Luria, C. A. Knight, L. M. Black, A. Lwoff, A. Garen, L. M. Kozloff, G. S. Stent, C. Levinthal, F. Jacob, E. L. Wollman, F. W. Stahl, S. G. Anderson, A. Gottschalk, F. B. Bang, A. Isaacs, W. Schlesinger, F. L. Horsfall, F. Fenner, J. Cairns, T. Francis, H. B. Andervont, K. M. Smith. With such a galaxy of talent, although the articles are not all of the same quality, it need scarcely be said that in total they contain a wealth of information and that the volumes will be required equipment of laboratories where viruses are being studied. This is probably more than enough to justify the exercise, but it is impossible not to regret that, valuable as these collected articles are, they do not constitute the definitive work on viruses these authors might have produced.

Each volume has a subject and author index, and each article its own bibliography, some running to hundreds of titles. There are many illustrations and the whole production is excellent, as it ought to be at a total cost of 41.50 dollars.

F. C. BAWDEN

TRENDS IN METROLOGY

Acta Imeko 1958

Proceedings of the International Measurements Conference, Budapest, 24-30 November 1958. Vol. 1: Pp. 443. Vol. 2: Pp. 444. Vol. 3: Pp. 372. Vol. 4: Pp. 460. Vol. 5: Pp. 419. (Budapest: Hungarian Scientific Society for Measurement and Automation, 1959.) n.p.

THE published proceedings of the 1958 International Measurements Conference, the first to be organized by scientific societies in Hungary, Poland and the U.S.S.R., provide Western readers in particular with a convenient means of reviewing the present state and development of metrology and instrument technology in these and other countries of Eastern Europe. Seventy of the 127 papers originate from the organizing countries, and there are 37 from the German Democratic Republic with six from Czechoslovakia. In addition, there are two each from Austria, the German Federal Republic, Italy, the United Kingdom and Rumania, and one each from Belgium, Bulgaria, Denmark and the Netherlands. The official languages of the conference were Hungarian, Russian, German and English (or French). As summaries in English are provided with 121 of the papers printed in languages other than English or French, it is possible for readers of English to gain a reasonable first impression of the contents of practically all the papers without recourse to translation. At the end of each volume is reproduced, in each of the four official languages, a list of the titles and authors of the papers appearing therein. No discussions of papers are recorded.

The conference was organized into three main sections dealing with the following topics: (1) Contributions of general interest (10 papers); (2) (comprising 9 sub-sections) geometric quantities; mechanical quantities; optical measurements; temperature, flow and humidity; electric quantities; magnetic quantities; electric and electronic measuring techniques; chemistry, physical chemistry and structure analysis; measurement and application of the ionizing radiations (102 papers in all); (3) organization, economy, technology and education (15 papers). Among the contributions of general interest appearing in Volume 1, mention is made of those on the international organization of both scientific and legal metrology, on international standardization and on the progress towards adopting natural reference standards, for example, an atomic wave-length, an atomic frequency and a constant, such as the gyromagnetic ratio of the proton, as the means of practical definition of basic units of measurement. Other papers discuss the applications of electronics, radio and microwave methods, semiconductors and digital computers to the techniques of measurement and control.

Papers in the various sub-divisions of Section 2 appear in the latter part of Volume 1, and in Volumes 2, 3, 4 and part of Volume 5. The two contributions from the United Kingdom fall in this Section; one deals with problems of determination of particle size by scanning microscopy (W. T. Welford), and the other describes an X-ray diffractometer operating automatically through a punched-tape programme (W. A. Wooster). Among methods and apparatus for measuring geometric and mechanical quantities, attention may be directed to the highly developed applications of optical interferometric methods in the U.S.S.R. and to the novel Czechoslovakian system,

applicable to gear and angle measurements, which depends on the use of sinusoidal magnetic impressions recorded on tapes or bands as highly sensitive and accurate angle-measuring devices. A paper in Volume 3 on the calibration and examination of electronic and visual pyrometers in the U.S.S.R. refers to pyrometers which are available for measuring temperatures up to $10,000^{\circ}\text{C}$. to an accuracy of 0.1 per cent (0.05 per cent at the gold point, $1,063^{\circ}\text{C}$.). Another paper discusses the measurement of radiation energy with a platinum bolometer sensitive to 10^{-10} W . Indeed, a very large proportion of the papers in Volumes 3 and 4 describe special instruments and techniques developed for use in the various fields of measurement covered. The U.S.S.R. paper on reference measurements for the ionizing radiations (Volume 5) shows that standards and measurements in this important field are well controlled by the work of the national standards laboratory in Leningrad. Contributions to Section 3 in Volume 5 reveal the intense interest, especially in the U.S.S.R. and the associated countries, in the applications of automation to methods of production and the control of inspection.

It is difficult for a single reviewer to give in brief an adequate indication of the wide scope and interest of the papers appearing in these five volumes. There is no doubt that, on the whole, they will amply repay notice by all those interested in the present-day trends of metrology and instrument technology. Preparations are in hand to hold another conference of the same kind during 1961 (June 25–July 9).

H. BARRELL

FLUCTUATION NOISE IN RADIO CIRCUITS

Electrical Noise

Fundamentals and Physical Mechanism. By Dr. D. A. Bell. Pp. x+342. (London: D. Van Nostrand Company, Ltd.; Princeton, N.J.: D. Van Nostrand Company, Inc., 1960.) 50s.

TO the electrical engineer, the title "Electrical Noise" might convey the impression that this book deals with unwanted radiation causing interference with telecommunications. The author is not, however, concerned with this field; and his book deals comprehensively with the fluctuation-type noise which arises within the apparatus and components used in the generation and reception of radio signals. It summarizes the results of more than twenty years experimental and theoretical research on the random fluctuations of current which arise from various causes in electrical circuits over a very wide range of frequencies.

Following introductory sections on mathematical techniques and general noise theorems, there are chapters on noise in diodes, grid-controlled amplifying valves, and the more recently developed beam, maser and parametric amplifiers. Current noise, which is generated when a direct current passes through a semiconducting material, is then discussed in considerable detail; and it is shown that the satisfactory explanation of the origin of such noise is an important outstanding theoretical problem. Further chapters deal with the types of noise which arise in thin metal films, in rectifiers and transistors, and in ferromagnetic materials. A chapter on "Radiation Detectors" shows that the measurement of noise can

be applied to useful ends in, for example, radio astronomy, temperature measurement, and photo-electric detectors.

The book is to be welcomed as a specialist monograph presenting a detailed review of the current state of knowledge of a subject in which there has been a certain amount of confused thought and much controversy in the past. Although the author has on occasions appeared to be in conflict with his contemporary workers in parts of this controversy, this has not materially affected the scope or presentation in the book under review. A good selection of references is given at the end of each chapter; these will enable the serious student to explore any part of the field and examine the points of view of other advanced research workers. The book has a few short-comings in that the chapter sub-headings are inadequate in some cases, and some of the diagrams are by no means self-explanatory. Apart from such limitations, however, the book is welcomed as a very useful survey of knowledge in this rather complex field.

R. L. SMITH-ROSE

PLANT PATHOLOGY

Plant Pathology

An Advanced Treatise. Edited by J. G. Horsfall and A. E. Dimond. Vol. 3: *The Diseased Population, Epidemics and Control.* Pp. xiii+675. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1960.) 27 dollars.

AS the editors make clear in their prologue, this third and final volume of their comprehensive theoretical treatment of plant pathology covers the newer or younger aspects of the subject, and to that extent it is truly theoretical in places. After a stimulating discourse by S. D. Garrett on the various forms of inoculum and on inoculum potential, there are chapters dealing with the natural spread of inoculum in soil, seeds and planting material, by animal and insect (mainly virus), and by air and water, including take-off, flight and landing. Other chapters deal with the analysis of factors and processes involved in primary and secondary disease epidemics, the possibility and value of predicting epidemics, and the biological factors that affect or interfere with them. The rest of the volume is concerned with the basic principles of disease control by cultural practices, soil treatment, the use of fungicides, the breeding of resistant varieties and plant legislation. Plant legislation, concealed under the misnomer "Quarantines", includes a useful account of recent international efforts to ensure that essential regulations are uniform, justifiable and soundly based biologically. The intricacies of this subject are, however, largely a closed book to all but a few officials, and many readers would no doubt have welcomed a reasoned exposition of the basic principles and problems involved, especially by one so well qualified to prepare it.

The international nature of the treatise is well maintained, with six contributions from the United States, four from the United Kingdom and single ones from Germany, Denmark, France and South Africa. The treatise is intended for the creative worker and advanced student of plant pathology, but even he will not get wholly by without more than a nodding acquaintance with mathematics and chemistry. But those who can spare £25 for the three volumes will find that the fifty distinguished contributors have given them plenty to think about. W. C. MOORE

Advances in Space Science

Vol. 1. Pp. xii+412. (1959.) 12 dollars. Vol. 2. Pp. xiii+450. (1960.) 13 dollars. Edited by Frederick I. Ordway. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd.)

THE title of this series is misleading. It would be much more indicative of the contents if it were "Advances in Space Technology". The editor's view on 'space science' is revealed in the foreword where he states that "The principal objective of space science is to make it possible for man, and not merely instruments, one day to travel into space and to explore the planetary and satellite bodies of the solar system (and perhaps, in some undiscernible future, even the stars)".

The headings of the articles and the authors (most of whom are affiliated to American military or industrial laboratories) are as follows: Volume 1, "Interplanetary Rocket Trajectories" (D. F. Lawden), "Interplanetary Communications" (J. R. Pierce and C. C. Cutler), "Power Supplies for Orbital and Space Vehicles" (J. H. Huth), "Manned Space Cabin Systems" (E. B. Konecni), "Radiation and Man in Space" (H. J. Schaefer), "Nutrition in Space Flight" (R. G. Tischoer), "A Decimal Classification System for Astronautics" (H. H. Koelle); Volume 2, "Experimental Physics Using Space Vehicles" (C. P. Sonett), "Tracking Artificial Satellites and Space Vehicles" (K. G. Henize), "Materials in Space" (F. L. Bagby), "Plasma Propulsion Devices" (M. Camac), "Electrostatic Propulsion Systems for Space Vehicles" (E. Stuhlinger and R. N. Seitz), "Altitude Control of Satellites and Space Vehicles" (R. E. Roberson).

The articles, which are in general highly technical, are likely to be of interest mainly to professional engineers. They are not intended for, and would not be understood by, the general reader.

Author and subject indexes are supplied to each volume. The printing and production are of the customary high standard of the Academic Press.

D. R. BATES

Modern Aspects of Electrochemistry

No. 2. Edited by Dr. J. O'M. Bockris. (Modern Aspects Series of Chemistry.) Pp. ix+416. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1959.) 75s.

THIS book continues the survey of selected topics in electrochemistry begun in the first volume, published in 1954. There are five chapters, dealing with the present state of the theory of electrolytic solutions (by H. Falkenhagen and G. Kelbig), physical chemistry of ion exchange resins (by J. A. Kitchener), molten electrolytes (by H. Bloom and J. O'M. Bockris), the anodic behaviour of metals (by T. P. Hoar), and the semiconductor-electrolyte interface (by M. Green). Each chapter has a full bibliography; the literature references seem mostly to end about 1955.

The first chapter is a very informative and detailed review of a subject which continues to attract interest. It is really a small monograph, the theory being developed from the beginning with the Debye-Hückel treatment. The mathematics is often rather advanced. Activity coefficients, conduction, and

(rather briefly) viscosity are dealt with, and there are many tables. The chapter on ion-exchange resins is on the lines of a small book on the subject published fairly recently. The discussion of molten electrolytes deals with a subject of increasing importance; Russian work, as well as that of the authors, find places in it. There are several tables of results, and the treatment is well balanced between theory and experiment.

The chapter on anodic behaviour of metals includes topics of technical importance, such as anodic polishing, and also deals with subjects of theoretical interest. The phenomena are still far from completely understood. The final chapter, on the semiconductor-electrolyte interface, is almost entirely theoretical, with only a brief discussion of the germanium electrode; the subject was scarcely at such a stage as to warrant a review. The book as a whole is very well written, with a good balance in each individual chapter, and good editing has brought together a most interesting selection of material.

J. R. PARTINGTON

Proceedings of the International Symposium on Microchemistry

Held at Birmingham University, August 20th to 27th, 1958. (Organized by the Midlands Section and the Microchemistry Group of the Society for Analytical Chemistry.) Pp. xxvi+583. (London and New York: Pergamon Press, 1960.) 100s. net.

THIS volume consists of a collection of lectures delivered at the International Symposium of Microchemistry held at the University of Birmingham in 1958. Many of the contributors are world-renowned in their respective fields, and the individual papers present a wealth of authoritative practical and theoretical information. Some papers also deal with the unique problems associated with the teaching of micro-analytical methods.

I almost feel it invidious to single out individual authors or topics for consideration, but the wide field covered by this remarkable book can only be illustrated in this way. F. Feigl's lecture to the whole meeting is devoted to the pyrolytic treatment of materials prior to spot-test analyses; F. J. Welcher reviews theoretically the employment of selective organic reagents; H. Weiss describes the more recent 'ring oven' technique; G. F. Hodaman and M. Corner present informative papers on 'weighing accurately'; H. Lieb reviews forty years of quantitative organic micro-analysis, and many other experts give supporting papers of great practical value. The practical fields of ion exchange, chromatography, polarography, radiochemistry, spectrochemistry and complexonistry are dealt with by chemists of standing, and one welcomes the papers by A. A. Benedetti-Pichler, C. J. Van Nieuwenberg and R. Belcher on the history and teaching of microchemical methods.

This is a book which will find a place not only with the individual researcher but also in the libraries of every up-to-date industrial or academic research institution. It offers, in small compass, a comprehensive survey of recent advances in widely separated fields of microchemical application and contains the valued opinions and laboratory experiences of many eminent research workers.

D. T. LEWIS

ORIGIN AND NATURE OF LUNAR SURFACE FEATURES

By J. J. GILVARRY

Research Laboratories, Allis-Chalmers Manufacturing Company, Milwaukee, Wisconsin

THE dark and smooth appearance of the lunar maria has generally been viewed as sufficient evidence to identify their surfaces as lava flows. Interpretations on this basis, but differing in detail, have been given by Baldwin¹, Urey², and Kuiper³. Gold⁴ has argued strongly against the presence of lava, in view of the consequent difficulty in correlating temporal sequences of crater origin and the paucity of definite volcanic features. I⁵ have pointed out that the known presence of a dust layer over the entire surface of the Moon vitiates the reasoning for the presence of lava. The arguments for lava presuppose the absence of a lunar atmosphere or hydrosphere lasting any significant length of time. During the past few decades, however, it has become increasingly clear that the terrestrial atmosphere and hydrosphere were formed by exudation from the Earth's interior. The purpose of this article is to consider the possibility of an analogous process in the case of the Moon. It will be shown that the origin and nature of major surface features on the Moon can be explained in terms of effects of the former presence of a lunar hydrosphere.

Life-time of the Lunar Hydrosphere

By considering the cosmic and terrestrial abundances of the inert rare gases, Brown⁶ and Suess⁷ have demonstrated that any element which existed primarily as a gas at the time of the Earth's formation could not have been retained to a significant extent in its atmosphere. It follows that the present atmosphere and hydrosphere of the Earth are not residual from primordial antecedents, but are almost entirely of secondary origin. Rubey⁸ has adduced purely geological arguments leading to precisely the same conclusion; he presents compelling evidence that the terrestrial atmosphere and hydrosphere were formed by leakage from the underlying earth through its surface.

In view of the Moon's smaller mass, the conclusion follows *a fortiori* that it could have retained no residue of any primordial atmosphere or hydrosphere, since it necessarily was formed at essentially the same distance from the Sun, at approximately the same time, and under roughly the same conditions as the Earth. Accordingly, the question of the life-time of a lunar atmosphere or hydrosphere cannot be discussed without deciding the type of secondary atmosphere or hydrosphere formed by leakage of fluid through its surface, by a degassing process exactly analogous to that postulated for the Earth. To answer this question, a scaling law must be assumed. It will be hypothesized that the total masses of a constituent in the secondary atmosphere and hydrosphere for the Moon and Earth should be proportional to the corresponding masses of these bodies. Let Q_i represent the number of molecules

above unit area on the Moon's surface for the i th constituent in its atmosphere and hydrosphere, and let Q_i^* be the corresponding quantity for the Earth. If the difference in mean density between the Moon and Earth is ignored, this assumption yields:

$$Q_i/Q_i^* = R/R^* \quad (1)$$

where R is the radius of the Moon and R^* that of the Earth. As will appear, the order of magnitude of resultant life-times is not sensitive to the precise choice of scaling law.

In determining the value of Q_i for fluids on the Moon from equation 1, it clearly is necessary to consider in Q_i^* the total amounts on the Earth of any compound of atmospheric or hydrospheric provenance. In the case of hydrospheric water, for example, one must include the contribution from continental ice, and in the case of carbon dioxide, the fossil quantity locked in sediments. Values of Q_i have been determined for water, carbon dioxide, oxygen and nitrogen by equation 1 from data of Wildt⁹. The resulting Q_i for water corresponds to a surface density of 79 kgm./cm.² and exceeds by a large factor those for the other fluids, as a consequence of the large mass of water in the terrestrial oceans.

For simplicity, it will be assumed that the secondary lunar atmosphere and hydrosphere were formed by exudation from the interior in a time short compared with the corresponding life-time. The life-time L_i of the i th constituent of the lunar atmosphere and hydrosphere is then fixed by:

$$L_i = Q_i/j_i \quad (2)$$

where j_i is the thermal escape-rate of Jeans¹⁰ and Spitzer¹¹. Equation 2 applies to the atmosphere and hydrosphere combined, since it presupposes that loss of a constituent (water vapour, for example) from the atmosphere can be replenished by gain from the hydrosphere. Thus, the model presumes that the entire hydrosphere is gaseous; the fact that it is liquid lengthens the actual life-time over that computed. It is unnecessary to consider the correction factor B of Spitzer¹¹ or my A_i (ref. 12) in connexion with equation 2, since use of these parameters is obviated when a direct estimate of Q_i is available. I have determined the height of the escape layer above the Earth's surface from data obtained by observation of satellite orbits¹³. Theoretical relations¹⁴ have been used to scale the result for night conditions to yield an approximate height of 2,300 km. for the escape layer above the lunar surface. The mean temperature of the critical level for the Earth varies between 1,000 and 2,000 °K diurnally¹⁵. An upper limit of 3,000 °K. will be assumed for the escape layer of the Moon, which is about the value apparently required to explain the loss of atmospheric helium-4 from the Earth^{16,17}.

Fig. 1. Life-time L_t of various constituents of the primitive lunar atmosphere and hydrosphere, as a function of assumed temperature in the escape layer. The curves for oxygen and nitrogen are indistinguishable on the scale used.

The life-time L_t on the assumptions made is shown in Fig. 1 as a function of assumed temperature of the escape layer, for water, carbon dioxide, oxygen and nitrogen. One sees that the life-time of water is the longest by a large margin for any temperature above 1,000 °K. Moreover, this life-time is measured in milliards of years, and thus is comparable with the duration (of order 4.5×10^9 years) of the Moon's life-time. Corresponding to uncertainties in assumed initial conditions, the estimates shown can reasonably be increased or decreased by a factor $10^{1/2}$, giving an overall spread of a factor of 10 in the results. The conclusion remains unaffected, that the lunar hydrosphere lasted a period at least of the order of 10^9 years. Computations of the life-time of water on the Moon have been made previously^{4,10}; they yielded values insignificant on an astronomical scale because the possible existence of a lunar hydrosphere capable of continuously replenishing the atmosphere was ignored.

The maximum depth of the lunar hydrosphere can be estimated on the assumption that the time of its exudation from the interior was short compared with its life-time. If the surface of the Moon below the hydrosphere were smooth, the value of Q_i for water would indicate a maximum water depth of about 1 km. However, about half the visible surface of the Moon consists of highlands about 2 km. higher on the average than the lowlands, which, if true for the other face, would yield a mean water depth of roughly 2 km. Height estimates for the averted face are not possible, since only a few crude photographs are available¹⁴. In spite of this uncertainty, it is clear that sufficient water existed in the lunar hydrosphere to drown all the lowlands and to encroach significantly on the highlands, at one time.

On these considerations, a large part of the erosion evident for the lowland regions of the Moon must have taken place subaqueously; a significant amount may have been done by turbidity currents¹⁵. Because

of the relatively low surface gravity, small area available for watersheds, and thinness of the atmosphere (composed in later stages primarily of water vapour), erosion by flowing rivers and their tributaries should not have been very significant. Thus, dendritic drainage patterns should appear in the highlands but should not be prominent; Pickering¹⁶ has shown observationally that such actually seems to be the case.

Craters on Land

If it is indeed true that the Moon possessed an appreciable hydrosphere throughout a large fraction of its history, it follows that the level floors of the maria were formed by sediments deposited from the water in the course of its dissipation. Compaction of these sediments should yield a softer rock than that forming the highlands, and this circumstance should be reflected systematically in the mensuration of the corresponding craters, to some degree. Evidence of a systematic difference between craters formed in the highlands and the maria will be sought in an extension of Baldwin's correlation of diameter and depth to include the effect of crater formation in hard or soft rock. Baldwin's curve of diameter versus depth for the lunar craters of Class I (presumably the youngest) exhibits a continuous variation through the analogous curve for terrestrial meteoritic craters into the corresponding curve for explosion craters on the Earth. This correlation is one of the strongest arguments that the lunar craters were formed by explosion of meteorites on impact. It can be shown that such explosions necessarily occur close to the surface¹⁷.

It will be assumed that the relation between the diameter D and depth d of a crater can be written as the quadratic form:

$$D = a_1 d [1 + (d/a_2)] \quad (3)$$

with the set of coefficients a_1 and a_2 different in the cases of hard and soft rock. The coefficients a_1 for hard and soft rock were determined from the results of measurements of the dimensions of craters formed by explosion of chemical charges in basalt and sedimentary rock, respectively¹⁸. These experiments were carried out under closely controlled conditions, with the centre of mass of the charge at ground-level. The resulting least-square linear relations $D = a_1 d$ for the two cases are shown (dashed in part) in Fig. 2. As a check, data points for the craters formed by the nuclear explosions Jangle (S) and Jangle (U) in compacted desert alluvium are shown also¹⁸; the latter was an underground explosion but the scaled depth of burst was sufficiently small for it to approximate a surface explosion. One sees that agreement of the two points with the line for soft rock is excellent.

Of the craters in Baldwin's Class I, 80 have been classified in Class IH, occurring in the highlands, 84 in Class IS, occurring in the floors of the maria, and 30 as ambiguous on this score. With the value of a_1 fixed as above for hard and soft rock, the corresponding values of a_2 were determined by a least-squares fit to the data of Baldwin for the dimensions of the craters of Class IH and IS, respectively. The resulting curves are shown in Fig. 2. They become nearly identical for large diameter and depth, as is clearly necessary, since the larger craters

Fig. 2. Correlation of diameter versus depth for various classes of craters and the lunar maria. The solid curves correspond to fitted functions for craters on land and in water, for hard and soft rock. In general, points for only every tenth lunar crater in Classes IH and IS appear.

on the floor of a mare must extend into the harder rock below the sediments. The association of the lunar craters of Classes IH and IS with hard and soft rock, respectively, is inferential; one sees that the difference between the two curves computed on this assumption is too small in the region of large dimensions to be of diagnostic value.

However, a significant difference does appear for the two curves in question for the intermediate range of depth and diameter. To show that the difference is real, recourse will be made to the data for terrestrial meteoritic craters. Ten such craters for which dimensions are known with relative accuracy were classified in Class IH, formed in hard rock, and Class IS formed in soft rock. The basis of distinction between hard and soft rock is the shear strength, primarily; granite and dolomite are regarded as hard, and limestone and sandstone as soft. Schist and gneiss are considered soft, in view of their low shear strength along planes of foliation and banding, respectively. The craters of Class IH are Brent²⁰, Chubb²¹, Holleford²², Sall²³, and Dalgara²⁴; those of Class IS are Barringer (Arizona)¹, Le Clot²⁵, Merewether²⁶, Odessa¹ 1, and Odessa¹ 2. The dimensions of these craters are plotted in Fig. 2, as differentiated into the two classes.

The close correlation between the data points for terrestrial meteoritic craters of Classes IH and IS, and the corresponding curves constructed on the assumption that the lunar craters of Classes IH and

IS were formed in hard and soft rock, respectively, is obvious from the figure. Furthermore, one notes that no data on the dimensions of terrestrial meteoritic craters were used in the construction of the curves in question, as is not the case for Baldwin's curve. In spite of this fact, the curves yield a separation of the terrestrial meteorite craters into two classes, for hard and soft rock, correctly. When corresponding coefficients of correlation are obtained for each type of crater, one finds that the values from this work exceed, or at least are equal to, those obtained using Baldwin's equation, in all instances.

The considerations of this article suggest strongly (but are insufficient to prove) that the rocks of the mare floors are sedimentary in origin. On this basis, they should be softer than the rocks of the highlands, and not basalt from lava flows. This view is diametrically opposed to those generally current. That the maria are vast pits filled with dust, as asserted by Gold⁴, is rendered highly unlikely by observed dimensions of craters formed in clay and marine muck¹⁸. Least-square lines for craters in these materials, analogous to those for hard rock and soft rock, appear in Fig. 2; the order of decreasing shear strength corresponding to the curves is to the right. Since dust has negligible shear strength, the points for the lunar craters of Class IS with smallest dimensions should be displaced far to the right in Fig. 2 if Gold's hypothesis were correct. Hence, the dust on the Moon, the presence of which is revealed by analysis of eclipse and radio observations⁵, is superficial in distribution.

Craters in Water

Baldwin's correlation curve applies only to lunar craters of Class I, as do the curves discussed in the preceding section. The remaining craters have been classified by Baldwin in Classes II, III and IV, in order of increasing age on the basis of apparent degree of erosion. When the dimensions of these craters are plotted in a diagram of the type of Fig. 2 the points lie in a broad band above the curves for Class I, at distances correlated roughly with the ordinal numbers of the classes. The nine craters of Class IV for which the representative points are displaced farthest from the curves for Class I have been placed in a separate Class V in this work. These craters are Hörbiger, Grimaldi, Schickard, Hipparchus, Ptolemæus, Neper, Letronne, Hansteen and Encke. The locus of the corresponding representative points in Fig. 2 represents the upper bound of the band in which all the lunar craters lie.

Baldwin explained the upward progression of the representative points with ordinal class of the craters in a plot similar to Fig. 2 as purely an effect of some unknown erosive process, filling the bottom at the expense of the rim after crater formation. A similar explanation is inherent in Gold's arguments⁴, but suggested erosive agents²⁷ seem insufficient. It will be asserted that the basic cause is a progressive change of the circumstances in which the craters were formed initially, corresponding to the gradual loss of the Moon's hydrosphere. Specifically, the relative dimensions of a crater were fixed by the depth of the water in which the meteorite exploded to produce the crater. The craters of Class V are the oldest and were formed when the hydrosphere was at its maximum depth. The physical arguments of Gilvarry and Hill¹⁷ can be used to show that the

impinging meteorite must explode close to the surface of the water. It is not denied that erosion is of some consequence in modifying the relative dimensions of lunar craters, but the process is assigned a secondary role in this connexion; however, the correlation of age and eroded appearance of a crater is assumed valid.

Glasstone²² gives curves for the dimensions of craters formed by nuclear bombs in strata lying under water, with the seat of the explosion close to the water surface. The curves apply specifically to a water depth of 18 m. for a bottom of soft rock, but conversion factors for a bottom of hard rock are given. It has already been established that the maximum depth of the lunar hydrosphere was at least 1 km. and possibly 2 km. Inspection of Fig. 2 reveals that these figures represent the order of the depths for craters of Class V. Accordingly, the dimensionless parameter μ defined by:

$$\mu = \delta/d \quad (4)$$

in terms of the water depth δ must have had closely the value unity for these craters, on the assumption that they are among the oldest. Therefore, to relate the lunar craters of Class V with terrestrial explosion craters, it is reasonable to make the correlation with explosion craters for which $\mu = 1$. The dimensions of two craters satisfying this prescription, Glasstone (*H*) and Glasstone (*S*) for a bottom of hard and soft rock, respectively, have been obtained from Glasstone's data and plotted in Fig. 2.

Since the points in Fig. 2 for the lunar craters of Class V lie at an extreme displacement from the curves for Class I, it will be assumed that they were formed in hard rock, in agreement with the relative positions of the points for Glasstone (*H*) and Glasstone (*S*). Their dimensions were fitted by a relation of the form:

$$D = a_1 d [1 + (d/a_2)^n] \quad (5)$$

where a_1 was fixed by means of Glasstone (*H*), and the coefficient a_2 and exponent n were determined by a least-squares fit to the data. The corresponding curve is shown in Fig. 2 (labelled hard rock). One sees that the points for Glasstone (*H*) and Class V lie on one smooth curve, roughly parallel to those obtained for the craters of Class I. The curve is not changed appreciably by an alternative choice of the dimensions of Glasstone (*H*), if the parameter of equation 4 lies in the range $1/10 < \mu < 2$.

The lunar maria can be divided into two broad classes. One class shows irregular borders. The other, of which Mare Imbrium is the archetype, is characterized by a nearly circular outline and the presence of an encircling ring of mountains, with an escarpment on the inner wall and a gradual slope on the outer face. It will be hypothesized that the maria of Imbrian type were formed by explosions of large meteorites, occurring at a time when the lunar hydrosphere exhibited roughly its maximum depth. If such were the case, the dimensions of these maria should show a correlation with those of the craters of Class V and Glasstone (*H*).

Values for the diameters of the maria have been given by Baldwin; the diameter was considered to extend fully to the encircling mountains (the Altai in the case of Mare Nectaris). The maximum height of these mountains can be taken as a first approx-

Fig. 3. Map of the southern half of Reindeer Lake, showing Deep Bay and the outline of the extinct Pleistocene lake. The crosses indicate spot elevations, with heights in metres above the present level of Reindeer Lake.

imation to the corresponding crater depth; values were taken from results of Schmidt²³, in general. This estimate can be improved by including a correction for the depth of the sediments in the mare basin. As an upper limit, Baldwin gives roughly 2 km. as the depth in question for the maria; this value was adopted for the largest mare (Imbrium) and scaled linearly with diameter for the others. Representative points determined in this manner are shown in Fig. 2 for Mare Imbrium, Nectaris, Serenitatis, Crisium and Humboldtianum. One sees that the points lie closely on the curve already determined from mensuration of Glasstone (*H*) and the craters of Class V.

As compared with the corresponding argument for the craters of Class I, the reasoning indicating that the Imbrian maria, the craters of Class V, and Glasstone (*H*) form one family lacks a link in the form of terrestrial meteorite craters. However, a meteoritic crater exists which one can argue reasonably must have been formed in water. This crater is Deep Bay²⁰, which is a nearly circular appendage of Reindeer Lake in northern Saskatchewan, Canada, as shown in the map of Fig. 3. It has not been possible to fix the geological age of this crater with any degree of certainty. However, Reindeer Lake occupies the site of an extinct Pleistocene lake of considerably larger area, as Fig. 3 shows²¹. If Deep Bay actually is of Pleistocene age, it most probably was formed in water, and the spot elevations above the level of the present lake appearing in Fig. 3 indicate a value $\mu \approx 1/2$ for the parameter of equation 4.

Deep Bay was formed in schist and gneiss, and thus in soft rock on the criteria adopted. To construct a curve for meteorite craters formed in water for a bottom of soft rock, a_1 of equation 5 was fixed by the dimensions of Glasstone (*S*), and the values of a_2 and n were taken as already determined from the craters of Class V. The resulting curve is shown in Fig. 2 (labelled soft rock). One notes that the point for Deep Bay lies on it closely. The bottom of Deep Bay has not been bored, but would have to

consist of roughly 1 km. of glacial debris for the representative point in Fig. 1 to fall reasonably close to the curves for craters of Class I. Such a large value is inconsistent with the fact that at least one glacier passed over Chubb but left relatively little glacial deposit in the crater; it is necessary to presume that freezing of the lake in a crater protects it from glacial filling³¹. Note that the points for both Deep Bay and the lunar maria have been fitted without making use of their dimensions in constructing the fitting function.

If the dimensions of the lunar craters of Classes II, III and IV (exclusive of V) are fitted separately in each case, the corresponding curves lie between those for Class I and the curve determined by Glasstone (H) and the craters of Class V, in a progression corresponding to ordinal number of the class. On the thesis of this article, this progression corresponds to formation of craters at temporal stages in the dissipation of the lunar hydrosphere, where the average water-level was below the maximum. Terrestrial analogues of these craters of intermediate type probably exist in the Campo del Cielo crater field³² in Argentina. The meteorite fall occurred in marshland; the dimensions of one of the largest craters are known with reasonable accuracy from excavation and the corresponding point occupies an intermediate position relative to the curves of Fig. 2.

Discussion and Conclusions

It is clear that the presence of a lunar hydrosphere of the age calculated yields a direct explanation of the progression of relative dimensions of the craters in the various classes, of the origin of the maria, and of the nature of the mare floors. It is ironical that, on these views, the name mare is correct on the basis of provenance.

The considerations of this article have a direct bearing on the problem of the origin of tektites. Nininger³³ has proposed that these glassy objects are fragments of rock fused initially by meteorite impact on the Moon and ejected from the lunar surface by the force of the explosion. The second melting phase displayed by these objects then occurred during supersonic passage through the Earth's atmosphere. Objections to the possibility of a swarm of bodies from the Moon falling on the Earth in a compact cluster seem to have been disposed of recently by Baker³⁴. Thus, the theory yields properly two periods of fusion, the observed flow structure and shape of these objects, and the distribution over the Earth's surface.

However, the chemical composition of most tektites is similar to that of argillaceous sedimentary rocks, and the view that such rocks could not be present on the Moon has precluded general acceptance of Nininger's idea. This objection is met fully by the considerations of this article. Erosion explains the presence of quartz particles in the lunar sediments, required to yield the lechatelierite observed in tektites. Thus the theory in question is the only one satisfying all the requirements laid down by Barnes³⁵.

It remains to explain the dark colour of the maria. Since only a small amount (less than 5 per cent) of organic carbon in a sediment is sufficient to yield a dark rock of low reflectivity³⁷, it will be postulated that a primitive form of life existed in the lunar hydrosphere. All the requirements for biopoesis were

once met on the Moon³⁸, in view of the existence for an extended time of an atmosphere and hydrosphere. Their presence would reduce the daily range of temperature below that at present observed³; if the albedo of the primitive atmosphere of the Moon were comparable with that of the Earth, the mean surface temperatures would be the same³⁹. The time-scale is favourable to the possibility in question, since the oldest known fossil plant (an alga) is at least 2.6×10^9 years old⁴⁰, indicating that life began on the Earth within a period less than 2×10^9 years of its origin. This maximum span for biopoesis to occur is less by 1×10^9 years than the minimum life-time shown for water in Fig. 2. Thus, one can speculate that life originated on the Moon through the process postulated by Oparin⁴¹. The initial steps were the formation of fairly complex organic molecules through the action of solar ultra-violet radiation and lightning discharges on atmospheric gases, as reproduced to some extent in the laboratory⁴².

A positive clue exists that life once existed in the lunar hydrosphere. As this medium dissipated, the dark coloration in the maria of Imbrian type tended to recede from the bases of the encircling mountains, as is evident in the pattern of light and dark colour in the mare basins. The retreat is most prominent in the case of Mare Nectaris, where the dark material has regressed about 100 km. from the ring defined by the arc of the Altai Mountains⁴³, but it appears also for Mare Crisium, Mare Serenitatis and Mare Imbrium. It is characteristic of living matter to follow the retreat of its habitat in this manner.

The inferred presence of organic carbon in the maria and adjacent craters would explain in a natural way Kozyrev's observations⁴⁴ of the Swan bands of C₂ as the result of sublimation of carbon by the heat of a meteorite impact. Accordingly, the observations can be explained without the need to invoke volcanism on the Moon, for which no visible evidence exists otherwise, on the thesis of this article.

A full account of this work will appear elsewhere.

I wish to thank E. W. Price, Dr. R. G. Greenler and Dr. W. S. Rothwell for discussions, and Helen Jackson for computational work.

PROGRESS OF CANCER RESEARCH

SOME hundreds of investigations are described in the current annual report of the British Empire Cancer Campaign which in 1959 gave financial support, directly or indirectly (£750,000) to more than 1,300 investigators at numerous centres of research in Great Britain and the Commonwealth*. The 666 pages of the report demonstrate, if that were necessary, that notwithstanding the immense industry expended, we are still a long way from the solution of cancer.

The subject-matter of the report can be conveniently subdivided into three main classes: (1) researches dealing with carcinogenesis, chemotherapy, demography, hormones and allied lines of work of a more biological or biochemical nature; (2) clinico-pathology and related themes; (3) physics, radiobiology, isotopes and radio-therapeutics.

Perhaps the most interesting recent development in class 1 has been the additions to the catalogue of cancer-inducing viruses, namely, the filterable mouse leukaemia agents of Gross, and the polyoma virus studied by Stewart which evokes tumours in a number of sites in mice. Work on these viruses is in progress at several research centres: Miller, at the Chester Beatty Institute, London, found that his cell-free filtrate prepared from the leukaemic tissue of mice of the high leukaemia-susceptible strain *AKR*, when injected into new-born mice of the *C₃H* strain produced a low incidence of leukaemia (13 out of 169 mice developed the disease); the induction of immunological tolerance in *C₃Hf* mice, produced by first inoculating them intravenously at birth with healthy spleen cells from *AK* mice, did not increase the susceptibility to leukaemia by the injection of leukaemic filtrate from *AK*'s at one month of age. Miller has also prepared filtrates from Gross's own leukaemic mice (*C₃Hf/GS* strain); these filtrates induced leukaemia in 27 per cent of *C₃Hf* mice in Miller's colony, which were much less susceptible to leukaemogenic filtrates from the tissues of *AKR* mice. The deoxyribonucleic acid and ribonucleic acid prepared by Kirby's method from this very active filtrate retain some of their potency, for on injection into new-born *C₃Hf/GS* mice, tumours of the salivary gland developed after a few months. Thymectomy

prevented leukaemia in strains inoculated at birth with leukaemic filtrates even in strain *C₃Hf/GS*, which gives 100 per cent leukaemia in the normal non-thymectomized litter mates.

Metcalf in Victoria points out that the thymus produces more than 75 per cent of the lymphocytes in *C₃H* mice, and that pre-leukaemic mice of the *AKR* strain show a 2-3 times higher daily production of lymphocytes than normal *C₃H* mice; when the *AKR* mice become leukaemic, the mitotic rate rises to twice as high as in the pre-leukaemic animal.

Salaman and Rowson, at the London Hospital, in work on the Gross and Stewart viruses, found that the inoculation of *C₃H* mice with cell-free filtrates from leukaemic tissue of *AKR* mice resulted in a high yield of tumours in less than three months; these were not leukaemias but were tumours of the salivary glands and subcutaneous carcinoma and sarcoma (40 tumours in 15 out of 23 treated mice). These tumours were similar in type and distribution to those described by workers in the United States as initiated by the 'P' or polyoma virus; a few leukaemias appeared later, between 14 and 20 months. In further experiments some litters were found to be immune to the carcinogenic activity of P virus, while other litters were highly susceptible, which strongly suggested that immunity had been spreading through Salaman's mouse colony and had effected complete protection in some litters, less or none in others. He found, also in agreement with Stewart and her colleagues, that tissue cultures of *OBA* mouse embryo cells treated with cell-free filtrates from lymphatic tissue of an *AKR* mouse bearing spontaneous leukaemia gave rise to a cytopathogenic and haemagglutinating agent; antibodies to this agent could be detected patchily distributed in his colony of mice, and the cell-free filtrates from the P virus-induced tumours contained antibody to the haemagglutinating agent. Salaman observed that tumours of the salivary gland and subcutaneous tissue which had been induced in *C₃H* mice by the inoculation of cell-free filtrate from leukaemic tissue of *AKR* mice contained haemagglutination-inhibiting antibody which could well account for the failure of these filtrates to evoke tumours on injection into new-born mice.

Orr and his collaborators at Birmingham have been investigating the chemical induction of ovarian and mammary tumours in mice of the 1F strain by painting the skin with 9:10-dimethyl-1:2-benz-

* Thirty-seventh Annual Report covering the year 1959. Part 1. The Chairman's Statement and the Accounts. Part 2: The Scientific Report of the Researches undertaken by the Central Organization and Its Autonomous Councils in the United Kingdom, and by some of Its Affiliated Organizations Overseas. Pp. iv+666. (London: British Empire Cancer Campaign, 1960.)

anthracene (DMBA). "In a recent experiment, ovariectomized mice were grafted with one ovary from a DMBA-treated mouse and one normal ovary. No ovarian tumours developed, showing that the presence of secretion from a normal ovary can prevent potentially neoplastic ovaries from developing into tumours. This falls into line with results obtained by other workers on the induction of ovarian tumours by X-rays or intrasplenic grafting, which techniques also fail in the presence of normal ovaries or adequate ovarian hormones." Tumours of the breast in male mice resulted when the skin was painted with methylcholanthrene after pretreatment of the rudimentary mammary tissue by stimulation with the injection of oestrogen together with progesterone or the subcutaneous grafting of an ovary. Progesterone secretion seems to play an important part in this type of mammary tumour; virgin females of the *C₅₇B1* strain are much more resistant to breast tumour induction by painting of the skin with methylcholanthrene, but if the mice are kept pseudopregnant by mating with vasectomized males and painted with methylcholanthrene or 9:10-dimethyl-1:2-benzanthracene, breast tumours appear in a very short time.

Workers at the Nottingham centre and at the Royal College of Surgeons have been using the fluorescein-globulin staining technique studied by the Australians, King, Hughes and Louis, who also contribute an account of their experiments to the report; they originally found that a fluorescein-globulin complex combines with some components of the tissues to give fluorescent staining which could be observed in the microscope. It was found that "normal tissue stains but malignant tissues uniformly fail to stain and this applies to both experimentally produced and naturally occurring growths". The cytoplasm of the cells took up the fluorescein-globulin stain, while the nuclei remained free from stain; but there were some exceptions, such as the tissues of the nervous system, haemoglobinized red corpuscles, megakaryocytes and connective tissue cells, which all failed to stain. Red blood corpuscles which still retained their nuclei (normoblasts from human bone marrow and the nucleated cells of lower animals) showed nuclear instead of cytoplasmic staining, and when the connective tissue cells enlarged and showed a considerable amount of cytoplasm these stained in the normal manner. Cells in tissue culture stained during the first 3- or 4-days growth in the normal manner, but after the fourth day failed to stain. These results show that staining capacity cannot be considered a reliable test for malignancy; the lack of staining has been put forward as the indication of a loss of some protein components in cancer tissue, but the unstainability of some normal tissues and of *in vitro* cultures of normal tissues pose questions demanding further investigation.

At the Glasgow centre, work is in progress on the lung cancer - cigarette-smoking problem. "For sixteen countries surveyed, a close relationship exists between national consumption of cigarettes 20 to 25 years ago and standardized mortality of men for lung cancer at the present time . . . an exception is the United States of America where the mortality is lower than would be expected from the apparent level of cigarette consumption." The anomaly has apparently been solved by the measurement of the mean length of butt of smoked cigarettes in Britain and in the United States . . . "on the basis of average butt lengths discarded by British and American

smokers . . . it would appear that the American smoker receives approximately 65 per cent of British smoker's smoke intake" (that is, the carcinogens contained in the tar of the smoke condensate).

The incidence of cancer in Jamaica has been studied at the Cancer Registry in the University of the West Indies. Statistical analysis shows that compared with Denmark the overall incidence of cancer is approximately the same, but the sites of election are rather different. Cancer of the upper respiratory and alimentary tract and of the lip, tongue, oesophagus, liver, cervix and penis appear to be more common in Jamaica in both male and female; but gastrointestinal malignancies are less frequent.

In the field of clinico-pathology the results obtained in exfoliate cytology as a means of detecting carcinoma of stomach and prostate are of interest. Price's report from Bristol suggests that the abnormal seasonal presentation of osteogenic sarcoma of adolescents may be related to the seasonal rhythm of the growth of bone. Prof. Hou's investigation of primary carcinoma of the liver due to infestation with *Olonorchis sinensis*, suggests that the worm requires a high level of copper in its environment in order to maintain its physiological functions. The report from St. Mark's Hospital is an admirable synopsis of significant clinical and pathological features of neoplastic disease of rectum and anus; the general results of the surgical treatment of rectal cancer for the period 1928-57 have been analysed, and among other facts revealed by this investigation are the following: the operation of combined excision of the rectum and sigmoid colon, which in recent years has replaced the older one of perineal excision almost to the exclusion of the latter, does not significantly improve the results in the less-advanced cases, whereas the survival for advanced cases is almost doubled. This advance has been made possible not by better surgery, nor is the operation itself an innovation, but by the improved anaesthesia and pre- and post-operative care which modern technique has made practicable. Thirty years ago it was far more hazardous for a patient to undergo the more radical procedure. The chances of cure of carcinoma of the rectum are expressed as follows: if the operation is carried out on patients in whom there is still a reasonable prospect of cure, between 40 and 50 per cent of the operation survivors are likely to be alive five years later. Some of those who have survived five years may succumb to a recurrence, but the majority of five-year survivors are likely to be cured.

What is to be expected from tests for 'cancer'? When extensive tumour deposits are present it is only reasonable to anticipate that there will be detectable alterations in the body fluids. These may be of a purely secondary nature, such as the hypercalcaemia and raised serum alkaline phosphatase which accompany gross bone involvement by tumour, or the raising of the erythrocyte sedimentation-rate associated with tumour necrosis or ulceration. But a test is very rarely specific, although malignant trophoblastic tumours and some cases of testicular tumour show a high serum and urinary level of chorionic gonadotrophin, assay of which may give a guide to the presence or not of functionally active tumour tissue in the body. Similarly, the malignant argent-affin cell tumours of the intestinal tract may be associated with a high urinary output of 5-hydroxy-indole-amino-acid. In general, however, no specific

alterations in metabolism, nor the production of abnormal substances is associated with the common cancers, for example, of the lung, bowel, and primary and secondary sex organs.

In the paper from the Pharmacology Department of the University of Melbourne chromatographic tests applied to extracts of specimens of urine from 'cancer' patients and control normal subjects have suggested the presence of weak organic bases in a concentration of the order of $1/10^6$ in the urine of 'cancer' patients. These substances, isolated in milligram quantities, have been crudely characterized by infra-red spectroscopy. A mention of the criteria used in the classification of these patients would have been helpful. The use of the term 'cancer patient' is to be avoided unless qualified. The varieties and stages of development of cancer are so numerous, their patterns of evolution so different, with consequent variations in prognosis, that the term has no more significance than, say, 'infectious disease' would have in a similar context.

The special contributions made by radiation physics and applied radioactivity are now so broad, merging especially with biochemistry and radiobiology, that the task of reviewing them is difficult. Some reports in the present volume do indeed deal with purely physical problems, but in most of them the physical contribution is firmly integrated into programmes which are fundamentally biological. This must be good both for the physicists and biologists involved and is a welcome departure from the usual trend of scientific research, which is towards ever greater specialization.

In radiotherapy, the most interesting points to note are the detailed work on the problems of using electron beams for therapy; the steady growth of interest in telecaesium units; and the development by the Radiochemical Centre of caesium-137-loaded tubes, the advantages of which as a replacement for radium are being investigated at the Royal Cancer Hospital. Illingworth's team at Glasgow has made notable advances in the technique of using yttrium-90 rods for pituitary irradiation, as an adjunct to the treatment of breast cancer. The use of unsealed preparations of radioisotopes administered parenterally for radiotherapy continues to lag as it has done for some years.

There have been no important new developments in the diagnostic use of radioisotopes, though several centres report improvements to existing techniques. Similarly, there are no new developments in isotope instrumentation; and in one important respect, the assay of tritium in biological samples, demand now outpaces supply. At least two centres report that they are working on the improvement of existing techniques, and there is no doubt that if these could be made simpler and more reliable this particularly useful tracer would be far more widely used than at present. The British Empire Cancer Campaign might do worse than devote some of its funds to a solution of this problem, thus saving the wastage brought about by divided effort.

Reading between the lines, one has an occasional feeling that, in the diagnostic and therapeutic fields especially, progress is not all it might be because various centres live too much in a world of their own. For example, it is clear from some of these reports that various hospitals have only recently begun to use the short-lived iodine-132 in place of iodine-131 for thyroid testing. Others are still improving

their techniques for administering radiogold colloid; and one has not yet passed beyond the primitive stage of using a heavily shielded syringe, presumably manually operated, for this purpose, which may well involve more than 100 mc. of radiogold. Now the palliative use of radiogold for the treatment of pleural effusions has been well established for at least ten years, during which time many simple methods of remote handling have been developed and published. In view of this, and of current concern with occupational radiation protection, it certainly looks as if some centres are leaving their improvements rather late in the day—though, of course, better late than never.

As usual, it is in research that the techniques of radiation physics and radioactivity continued to find their greatest application. The main emphases are on the vexed question of the proportionality of dose to effect in causing cancer; on the similar effect of dose-fractionation; on the effects of prolonged radiation exposure; and on the relationships between oxygen-tension and tumour radiosensitivity. Many centres are at work on these problems. The results are not startling; what is more important is that they are solid and impressive. The radiation degradation mechanisms of cellular constituents continue to receive detailed investigation.

In addition to this, many useful metabolic studies are reported. At the Royal Cancer Hospital it has been shown that diethylene-triamine-penta-acetic acid is more effective than ethylenediamine-tetraacetate in removing americium-241 from the body. The same centre has made comparative studies of the absorption of the alkaline earths from the gastrointestinal tract, showing, somewhat surprisingly, that the degree of absorption is not related to atomic weight, but that radium is more readily absorbed than barium. The Royal Cancer Hospital also continues its valuable work on environmental radioactivity and the natural activity of foodstuffs. The Department of Biochemistry at St. Bartholomew's Hospital has continued its work on zinc metabolism, showing among other things, that erythrocyte zinc, in contrast to leucocyte zinc, is higher in leukæmic than in normal blood. These are but a few of the many examples which might be quoted; selection is really invidious.

However, mention should be made of a new development by Mitchell's team at Cambridge, because of its direct relevance to the important question of cancer chemotherapy. For six years they have been trying to produce labelled organic substances which are selectively concentrated in tumour tissue. They have now succeeded, using tritium-labelled tetrasodium-2-methyl-1,4-naphthohydroquinone diphosphate (synkavit) of very high specific activity. The therapeutic possibilities of this agent are at present under investigation.

The size and, even more so, the method of presentation of these reports combine to defeat any realistic attempt at adequate summary. This is a matter which has received adverse comment before. To some extent the problem is insoluble; there are, and must be, dozens of authors, but some of these report in a few vague lines, others in several pages; and this disparity is not always related to the intrinsic importance of the work discussed. Some further editorial—or pre-editorial—advice to contributors is indicated. A much more serious objection is that the contents of the report continue to be laid out on a geographical basis, centre by centre. This system

not only has no scientific merit, it also renders the report as a whole almost unreadable because it is so disjointed; and, in the absence of an analytical index (indeed, of any subject-index at all), nothing short of leafing through every one of its 666 pages

will allow the reader to form any clear picture of what is happening in his own and related fields of interest.

TEST TRACK FOR THE ROAD RESEARCH LABORATORY

THE Road Research Laboratory was founded in 1933. In recent years the importance of the work being done both on road materials and methods of road construction and on traffic and safety problems has been responsible for increases both in staff and the facilities needed. The Laboratory has thus long out-grown the field at Harmondsworth on which the first buildings were erected, and various other buildings within a radius of 5 miles of Harmondsworth have been pressed into service.

The first stage in bringing all the Laboratory's activities together was accomplished on October 12, when the Laboratory's special test-track was declared ready for service. This has been built on a triangular site of some 253 acres of undulating wooded country immediately north-west of the village of Crowthorne in Berkshire. This site is ultimately to house laboratories, workshops, offices, a library and a canteen to provide all the facilities required for the Laboratory work and to accommodate some 750 members of staff.

The new track has cost about £500,000 to build and will be used mainly for research into traffic problems and safety measures with special attention to the behaviour of vehicles at high speeds. The type of investigation proposed cannot be carried out on public roads with safety, but abandoned airfields have been used from time to time.

The track is some 3 miles long, and is built in the form of a figure of eight, one loop being about twice as large as the other; the larger loop has a steeply banked bend leading to a straight portion 900 yd. long. For tests on stability during braking at high speed a car can thus take this bend at 60 m.p.h. left-handed, accelerate along the straight, which has a downhill gradient of 1 in 25, and then, while the track swings away to the left, take a siding which continues the straight portion for some 200 yd. and leads to a terminal area some 300 yd. long and 80 yd. wide. A car can thus enter the terminal area at 100 m.p.h. and be braked to a standstill in perfect safety. This area will be used for investigations of the stability of vehicles in good condition and defective when performing emergency manoeuvres involving steering, accelerating and braking.

Much remains to be learnt about the steering characteristics of vehicles under transient conditions. Theory and experiment need to be closely linked in this work, and the two large paved areas afford unrivalled facilities for obtaining experimental data at fairly high speeds. One of the demonstrations during the opening inspection showed an experiment of this type. A car with unbalanced brakes entered the terminal area at high speed and spun round several times before being brought to rest. The long straight section, which has been termed the 'high speed' section, is made up of six different road

surfacing for skidding experiments. A storage tank containing 54,000 gallons of water has been installed on a nearby bank with pumps and pipes so that some 800 yd. of this track can be kept wet during tests. This section of the track will thus enable investigations to be made of the effect on skidding of the texture and other properties of the wet-road surface, the properties of the tyres used and the characteristics of the vehicle as regards steering, braking and general ease of control.

The track as a whole will also be used for tests on vehicle lighting both on straight and curved roads with surfaces of different colours and textures, and also for comparison of different street lighting installations under controlled conditions, both types of test being hazardous when carried out on public roads. The track will also provide a continuous circuit where driving habits and reactions can be studied in safety: a demonstration of the technique involved was given during the opening inspection. Two cars followed each other both in wireless communication with a fixed receiving station. The experiment was to determine safe following distances; the first car carried out various manoeuvres, and the braking reactions, throttle position, speeds and other data involving the cars were recorded at the receiving station on a moving chart.

Where the tracks of the figure-of-eight cross, a circular centre area has been built with a diameter of 900 ft.; this is about the size of the grass area of Lords Cricket Ground. This centre area will be used to investigate large-scale problems of traffic control. Where the design of an intersection is being considered, for example, the several possible alternatives can be set up with moveable barriers and kerbs, and can be studied with actual traffic; variations in the siting and operation of traffic signals, and other aids to the flow of traffic can also be investigated.

In a complex network it may be possible to speed up the flow of traffic by a system of vehicle detectors and traffic lights controlled by a computer which adjusts the traffic controls according to the volumes of traffic signalled to it from the detector points. This central area will be available for practical tests of such systems. The track is also provided with a novel control feature. This consists of a straight wire running under the whole length, together with a series of wire loops at regular intervals. These wires can be made to emit various types of signal which can be picked up by electronic devices in the test vehicles and translated into instructions. Thus 'automatic pilots' can be used in experiments involving cars being crashed, and the loop system can be made to signal back to a driver the passage of a car over the loop in front. This system will be used to explore the possibility of providing guidance to the drivers of vehicles in dense fog.

T. LONSDALE

OBITUARY

Sir Harold Spencer Jones, K.B.E., F.R.S.

HAROLD SPENCER JONES was born in Kensington on March 29, 1890, and died there on November 3, 1960. He was educated at the Latymer Upper School, Hammersmith, and at Jesus College, Cambridge, where he was a wrangler and Smith's Prizeman and also obtained first-class honours in Part 2 of the Natural Sciences Tripos. He was elected a Fellow of his College in 1914, but a year before this he was appointed chief assistant at the Royal Observatory at Greenwich.

In 1923 he was appointed His Majesty's Astronomer at the Royal Observatory of the Cape of Good Hope. He directed this Observatory with great vigour for ten years, and interested himself personally in both the spectroscopic work, contributing full-scale studies of Nova Pictoris and of Procyon as a double star, and also the astronomical work, investigating the constant of aberration, the mass of Venus and the Moon's motion. He took the important decision to resume the Cape programme of parallax determinations, which had been set aside in favour of spectroscopic work. He, however, left the Cape before this programme was completed, and it was finished by his successor as H.M. Astronomer, John Jackson.

In 1933 Sir Frank Dyson retired from the position of Astronomer Royal, and Spencer Jones succeeded him, being the tenth person to hold the office since the appointment of Flamsteed in 1675. His major work during his first years at Greenwich was the reduction of observations made on the minor planet Eros, with the end in view of securing an improved value of the solar parallax. Eros made a close approach to the Earth in 1901, the minimum distance on this occasion being 30,000,000 miles. Observations of its position were reduced by A. R. Hinks, who found a solar parallax of $8.807'' \pm 0.0027''$ from photographic measures and $8.808'' \pm 0.004''$ from micrometer measures. However, it was realized that Eros would make a much closer approach to the Earth in 1931 (minimum distance 16,200,000 miles), and in 1928 the International Astronomical Union set up a commission with Spencer Jones as president to organize observations on a world-wide scale in the forthcoming favourable opposition. The circumstances of the opposition favoured observatories in the southern hemisphere, and in fact a great part of the weight of the determination came from observations at the Cape, which Spencer Jones was then directing. Spencer Jones's reduction and discussion of the work was not published until 1941; he obtained the value $8.790'' \pm 0.001''$, a result which differed substantially from that of Hinks. Spencer Jones was an authority on the consequential changes in the inter-related constants of the solar system and discussed the adjustment of them with great thoroughness.

In addition to his interest in the solar parallax, Spencer Jones took a deep interest in latitude variation and in the accurate determination of time, and he ultimately replaced Dyson's Shortt clocks with quartz clocks and commissioned a newly designed photographic zenith tube to determine both latitude variation, formerly determined with the Cookson floating telescope, and time, determined with a small reversible transit telescope. The photographic zenith tube was not brought into use until after

Spencer Jones's retirement in 1955; but the quartz clocks operated for many years under his direction, and he had the satisfaction of detecting with them variations in the rate of rotation of the Earth. This has important consequences on apparent motion of bodies in the solar system, which was a topic that Spencer Jones had already studied at the Cape.

Perhaps as a result of his service at the Cape, Spencer Jones was led to the view that Greenwich had become permanently unsuitable for astronomical observation, by reason of atmospheric pollution and the development of street lighting. He therefore set about persuading the Admiralty that it was necessary to move the Royal Observatory from Greenwich to a country site. Approval was obtained in 1946, and Herstmonceux Castle, with its associated estate of 372 acres, was purchased by the Admiralty: but the actual move proceeded somewhat slowly, the first stage taking place in 1948 and the move being incomplete when Spencer Jones retired in 1955. He, however, secured the building of premises outside the Castle such as to make the Royal Greenwich Observatory much better equipped than it had ever been at Greenwich and Abinger (the magnetic sub-station, at which a great deal of the time service was located), and the night sky at Herstmonceux has proved greatly superior to that of Greenwich.

Spencer Jones also realized that the want of a large modern telescope had had a crippling effect on British astrophysics, and he led the astronomical profession in representing to the Royal Society, the Admiralty and ultimately the Treasury, that a large telescope should be built. Approval was given for the building of a 98-in. reflecting telescope, to be called the Isaac Newton telescope, and to be set up in the grounds at Herstmonceux. The diameter of 98 in. was occasioned by the gift of a 'Pyrex' blank of that size by the McGregor Fund in the United States, a blank which had been made at the time of the casting of the blank for the 200-in. reflector. Again Spencer Jones did not continue in office long enough to see the result of this move, and in fact the project was delayed for a number of reasons. It is now expected that the telescope will be put into commission in 1966.

Spencer Jones was the recipient of many honours. He was created a knight in 1943 and K.B.E. in 1955. He received the Gold Medal of the Royal Astronomical Society in 1943 and a Royal Medal of the Royal Society in the same year. He was highly esteemed in international circles, and was president of the International Astronomical Union from 1945 until 1948, and he held all the offices in the Royal Astronomical Society, being president from 1937 until 1939 and foreign secretary at the time of his death. He became secretary-general of the International Council of Scientific Unions in his retirement. His interest in horology was recognized by his being made president of the British Horological Institute, and he received its Gold Medal in 1948; and he was twice master of the Clockmakers' Company—in 1949 and 1954. Perhaps his most important service to British astronomy consisted in his moving the Royal Observatory to the country and equipping it to take on an entirely new lease of life, and as such he occupies a distinguished position among the Astronomers Royal.

R. V. D. R. WOOLLEY

NEWS and VIEWS

The Royal Society: Officers

SIR HOWARD FLOREY has been elected president of the Royal Society in succession to Sir Cyril Hinshelwood. The new treasurer of the Society is Sir Alexander Fleck, formerly chairman of Imperial Chemical Industries, Ltd., and the new foreign secretary is Sir Patrick Linstead, rector of the Imperial College of Science and Technology, London. Sir Lindor Brown, Waynflete professor of physiology in the University of Oxford, and Sir William Hodge, Lowndean professor of geometry and astronomy in the University of Cambridge, have been re-elected biological secretary and physical secretary, respectively.

Other members of Council elected were: Prof. J. F. Baker, professor of mechanical sciences in the University of Cambridge; Mr. R. P. Bell, reader in physical chemistry, University of Oxford; Dr. J. C. Burkill, University lecturer in mathematics, University of Cambridge; Prof. D. G. Catcheside, professor of microbiology in the University of Birmingham; Prof. J. E. Harris, professor of zoology in the University of Bristol; Prof. T. M. Harris, professor of botany in the University of Reading; Prof. A. F. Huxley, Jodrell professor of physiology at University College in the University of London; Sir Christopher Ingold, professor of chemistry in the University of London (University College); Dame Kathleen Lonsdale, professor of chemistry in University College, London; Dr. R. A. Lyttleton, reader in theoretical astronomy in the University of Cambridge; Dr. R. G. Macfarlane, reader in haematology, University of Oxford; Prof. R. A. Morton, Johnston professor of biochemistry in the University of Liverpool; Sir Alfred Pugsley, professor of civil engineering in the University of Bristol; Dr. C. J. Stubblefield, director of the Geological Survey of Great Britain; Sir Gordon Sutherland, director of the National Physical Laboratory; Prof. C. H. Waddington, professor of animal genetics in the University of Edinburgh.

Sir Howard Florey, P.R.S.

SIR HOWARD FLOREY, professor of pathology in the University of Oxford, was born in Adelaide in 1898, where he attended St. Peter's College and the University, afterwards proceeding to Magdalen College, Oxford, as a Rhodes Scholar. After holding academic posts in the Universities of Cambridge and Sheffield, he was appointed to his chair at Oxford in 1935. He is well known for his contributions to experimental pathology and medicine, and especially for his work on the isolation, structure, therapeutic use and mode of action of penicillin, for which he was awarded the Nobel Prize for 1945, jointly with Sir Alexander Fleming and Prof. E. Chain (*Nature*, 156, 564; 1945). Among his many awards he has received a Royal Medal in 1951 (*Nature*, 168, 1017; 1951), and the Copley Medal in 1957 (*Nature*, 180, 1231; 1957) of the Royal Society.

Applied Science in the University of London:

Prof. B. G. Neal

PROF. B. G. NEAL has been appointed to the chair of applied science with special reference to engineering tenable at the Imperial College of Science and Technology, University of London, as from April 1, 1961.

This chair was first established in 1955 with the aim of giving special attention to the common course for all engineering students at the City and Guilds College and was held by Prof. D. G. Christopherson (see *Nature*, July 2, 1955) until he resigned the chair on September 30 last. Prof. Neal had a distinguished undergraduate career at Trinity College, Cambridge, where he won the Rex Mor, Ricardo, and Seely Prizes. After the War, he carried out research at Cambridge and at Brown University in the United States; after his return to Cambridge, he held appointments on the teaching staff until in 1954 he was appointed professor of civil engineering in the University College of Swansea. His research interests lie in the properties of materials, particularly structures and welded joints, and he has published many papers on the theoretical and experimental analysis of the stresses in such structures. He is keenly interested in current problems of education for engineers, and the new expansion and development of engineering at Imperial College will doubtless afford Prof. Neal many opportunities for guiding engineering education along the right lines.

British Scientific Policy and Research Effort

In the debate on scientific policy in the House of Lords on November 9, Lord Adrian intervened to make two points. He stressed the importance of the science teachers and their work and of associating them with the necessary re-examination of curricula in science. His other point related to the scientific societies which played an important part in any organization for both pure and applied science. While there were no serious complaints about the arrangements between the State and the scientific societies during the past 100 years, or about Government goodwill towards these societies, their finances were now seriously threatened by proposals of the Pritchard Committee, that in future societies which are now exempt from rates should be liable to the extent of half the full rateable value of their premises. Few of them had substantial financial resources, and one consequence was likely to be a reduction in the publications of learned societies. Lord Hailsham said he was aware of the position in general, but undertook to look into the question, and he suggested that Lord Adrian should induce the societies to memorialize him or the Chancellor of the Exchequer on the subject.

Referring to some of the gaps in the British research effort mentioned in the report of the Advisory Council on Scientific Policy, Lord Hailsham said that since the War the Government had financed the work of the National Institute of Oceanography, under the supervision of the National Oceanographic Council, to the extent of £1.5 million, and had recently approved the construction of a new oceanographic ship for the Institute costing about £750,000. He agreed that oceanography was essentially an international study, and he hoped shortly to have the opinion of the British National Committee for Oceanic Research, set up by the Royal Society, as to the part the United Kingdom could play. Various proposals involving international co-operation in astronomy were being considered and his office was also in touch with developments through the British National Committee on Astronomy of the Royal Society; he

thought it was important that there should be an early decision. The Government had accepted the Advisory Council's recommendation regarding the use of the telescope and equipment maintained at Pretoria by the Radcliffe Trustees, and specific proposals for additional financial help to the work at this observatory were under consideration by the Department of Scientific and Industrial Research. The recommendation relating to the establishment of seismological centres at the Universities of Cambridge and Edinburgh was in the first place a matter for the Universities concerned, and Lord Hailsham understood that they had it under active consideration. He added that he had given some attention to the matter of financing the administration of scientific departments although this was primarily a matter for the University Grants Committee.

Overseas Trainees and Students in Britain

Two recent booklets describe the increasing part being played by Britain in the education and training of students from Commonwealth and other countries overseas. The first, "Overseas Trainees in United Kingdom Industry", describes the opportunities available through scholarships provided by the British Council, Colombo Plan, Federation of British Industries Overseas Scholarships and other agencies, as well as the actual scales of assistance provided by the agencies (Pp. 16. London: Federation of British Industries, 1960. 6d.). The booklet has been prepared by the Federation of British Industries and shows clearly that the development of such facilities is as essential for the long-term growth of the British economy as for the benefit of participating trainees and their sponsoring countries. The second, "Overseas Students in Britain", is more concerned with what is being done by various welfare organizations to serve the 47,500 overseas students who are now in Britain (Pp. 34. London: London Overseas Dept. of the British Council, 1960. 1s. 6d. net). The booklet has been prepared by the Standing Committee of the London Conference on Overseas Students but has application throughout Britain. It may be obtained from the British Council, 3 Hanover Street, London, W.1.

Science and Technology for Commonwealth Students in Britain

IN a written answer in the House of Commons on November 23, the Secretary of State for the Colonies, Mr. Iain Macleod, gave a table showing that of the 2,230 students from territories under United Kingdom administration studying technical or scientific subjects in the United Kingdom, 235 were studying pure science, 708 medicine and pharmacy, 867 engineering and technology, 43 dentistry and 96 agriculture. Many of the further 1,150 students taking courses for the Ordinary and Advanced Level examinations of the General Certificate of Education in the United Kingdom will have included science among their subjects. A parallel statement on the same day from the Secretary of State for Commonwealth Relations gave the number of science and technology students from member countries of the Commonwealth in 1959-60 as 3,125, of whom 687 were in pure science, 1,203 in technology, 942 in medicine, 109 in dentistry, 129 in agriculture and forestry, and 55 in veterinary science. For the Federation of Rhodesia and Nyasaland the corresponding figures are: 19, 14, 33, 1, 8 and 11, giving a total of 86; and for the High Commission Terri-

ories the total was 6. In addition to 4,961 students from member countries of the Commonwealth enrolled in technical colleges in the United Kingdom in 1959-60, many of the approximately 2,000 students from these countries studying in private colleges and of the 830 students in teacher-training colleges would have included science among their subjects of study.

Government Grants to University and other Students

IN answering a question regarding grants to students in the House of Commons on December 1, the Minister of Education, Sir David Eccles, said that the Government has decided on the general lines of the revised scale of parental contributions. Details of the scale, which will come into force in October 1961, will be published shortly, after he has consulted the local authority associations. In addition to university students, the new scale will apply to students taking comparable courses in further education institutions and to teachers in training. No contribution would be required below £700—net scale income—and in general there would be a substantial reduction in the parental contribution. The income tax child allowance would be continued and the cost of the proposed relaxation would amount to about £10 million in a full year. The relaxation is to be without prejudice to full abolition of the means test if on examination this proved to be the right course. It is intended that all local education authorities should apply the scale uniformly, and the application of the decision to Scotland is still under discussion.

Training Nuclear Engineers and Reactor Physicists

IN written answers to questions in the House of Commons on November 24, the Parliamentary Secretary to the Ministry of Education, Mr. K. Thompson, as representing the Minister for Science, said that the University of Birmingham, the Imperial College of Science and Technology, Queen Mary College, London, the Universities of Manchester and Liverpool jointly, the University of Southampton, and the Scottish universities, jointly with the Royal College of Science and Technology, Glasgow, had applied for financial grants to cover the whole cost of building a low-power nuclear reactor, to provide better facilities for training nuclear engineers and reactor physicists. Sir Edward Boyle said that the Universities of Birmingham, Durham, London, Manchester and Southampton already offered facilities for training nuclear engineers and reactor physicists, and during the period 1956-60 an average of 90 students took postgraduate courses, and about 100 students chose nuclear engineering or reactor physics as an option in their final undergraduate year.

Report of the Faculty of Fisheries, Prefectural University of Mie, 1958-59

THE University of Mie publishes both a *Journal* and a report for the Faculty of Fisheries and both seem to cover similar ground. In the reports (published annually since 1951) a good balance is maintained between economic and non-economic subjects. Those of a practical application to fisheries are written in Japanese, usually with summaries in English, while the non-economic articles are, as a rule, in English. The periodical is well produced and has the support of leading Japanese scientists. In the reports for October 1958 and November 1959, which have recently become available, there are three

papers by S. M. Shiino on Japanese copepod parasites of fish, and one on bopyrid parasites of Crustacea (3, Nos. 1 and 2. Otanimachi, Tsu, Mie Prefecture: Prefectural University of Mie). He has written very extensively in this journal and elsewhere on these two subjects and has added enormously to the Japanese fauna. T. Ito and T. Iwai have nine papers (with English résumés) on the 'Mizukawari' in eel-culture ponds. This is the study of the grazing effects of brackish-water rotifers, on the phyto- and zoo-plankton of the fish ponds, and the physical and chemical changes brought about during this season. There are also four papers by J. Horiguchi (with English résumés) on biochemical work on the shell-fish *Pteria (Pinctada) martensii* (Dunker) and *Hyriopsis schlegelii* (v. Martens). Other articles deal with algae; the fishing capacity of different nets for small trawlers operating on the Ise Bay grounds; studies on fish-meat jellies; and some ecological studies on fish.

Cryogenics

CRYOGENICS technology is no longer confined to the large-scale liquefaction of gases, nor is low-temperature research conducted solely in university laboratories. The increasing use since the Second World War of cryogenic propellants, of liquid hydrogen for deuterium separation or bubble chambers and of liquid helium for superconductive computer elements and other electronic devices, illustrates the recent intensified and varied application of cryogenic methods. A warm welcome will therefore be given to the new quarterly *Cryogenics*, since it is the first international journal to be devoted solely to all aspects of applied or basic low-temperature research, engineering and development (1, No. 1; September 1960. Pp. 64. London and New York: Heywood and Co., Ltd., 1960. Subscription rates: £5 per annum (4 issues); 15 dollars; 90 NF.). The three joint editors, Dr. K. Mendelssohn (Great Britain), Dr. R. B. Scott (United States) and Dr. L. Weil (France), are supported by eleven advisory editors, who are all well known for their high reputations as active low-temperature research workers. The contents of the first number of *Cryogenics* consist of a review article by Dr. N. Kurti on the subject of cooling by adiabatic demagnetization of nuclear spins; nine original contributions with abstracts in English, French, German and Russian; two letters to the editors and two book reviews; and a bibliography of cryogenic literature covering the period January–May 1960. A complete bibliography up to date of all papers on low-temperature research, which has been made available to the editors by Arthur D. Little, Inc., is to be published in a special supplementary issue of *Cryogenics*, and two review articles scheduled for future issues are, "New Methods of Producing Cold", by H. O. McMahon, and "Irradiation at Low Temperatures", by L. Weil.

Use of Natural Gas In Britain

MR. P. G. INNEL CLEMENT, public relations officer to the National Coal Board (West Midlands Division), has written directing attention in amplification of the facts given in the article entitled "A British Source of Natural Gas" in *Nature* of October 29, p. 373, to what is being done to tap the natural gas resources of British coal mines. The extraction of coal causes fractures in the seams and in the surrounding strata, through which the trapped firedamp escapes into the

workings. The traditional way of dealing with it has been to dilute it to safe proportions in the underground ventilating current, but in some coal seams the emission of methane is so high that there is difficulty in diluting it to safe proportions. Techniques for draining methane in such circumstances as these have been developed in the past ten years. A technique now in increasing use involves drilling holes of narrow diameter, often 100 yd. long, through the strata at an angle of about 55° from the horizontal as the coal working face advances. The holes are fitted with equipment for measuring the flow and pressure of the gas, and for taking samples. The gas is extracted by exhaust pumps, and piped to the surface or to some point underground where the ventilation is sufficient to disperse it safely. In an increasing number of collieries, methane drawn from the seams is being pumped to the surface and put to practical use. Gas obtained in this way is being used at the rate of 2,700 million cu. ft. a year, most of which is being piped to the works of Divisional Gas Boards. In the North Staffordshire area of the West Midlands Division, four collieries are contributing about 500 million cu. ft. a year to the national total, and in the past month a Shropshire colliery has started to supply methane to a gas works. The effects of methane drainage are twofold: it improves working conditions underground, particularly from the safety point of view; and on an increasing scale it is putting a natural product to a practical use.

Safety Propaganda In Industry

POSTERS are widely used in the interests of accident prevention but little reliable information exists as to their efficacy. A recent report from the Human Factors Section of the Operational Research Department, British Iron and Steel Federation, published in *Occupational Psychology* (34, No. 3; 1960), suggests that appropriately chosen posters may appreciably reduce certain kinds of industrial hazard. In an experiment with specially designed posters carried out in six steel works, Dr. S. Laner and Mr. R. G. Sell have been able to show that the percentage of operations conforming with safety requirements (hooking of chain slings on to crane hooks) averaged over a six-week period after display of the posters rose very appreciably, in some cases by more than 20 per cent. No comparable improvement was noted in a similar steel works in which no posters were displayed. Interestingly, the slingers often found it difficult to recall what the posters were and many doubted their efficacy. It is suggested that the effectiveness of the posters may have derived from their relevance to a specific working situation rather than to safety in general. This point should be borne in mind by all concerned with the design of safety propaganda.

Shortage of Graduate Biochemists

EVIDENCE of a shortage of trained graduate biochemists in the United Kingdom emerged during the recent Biochemical Society colloquium on "The Organization and Financing of Research in Biochemistry and Allied Sciences in Great Britain" (see *Nature*, 188, 194; 1960). With the object of defining more closely the extent and the nature of this shortage, the views of those who employ biochemists are being sought. Information should be sent to Dr. K. S. Dodgson, Department of Biochemistry, University College, Newport Road, Cardiff.

Diseases of Wild Animals

THE part that apparently healthy wild animals play as the carriers of the causal agents of serious diseases in domestic animals and man has increasingly occupied the attention of workers in many parts of the world for many years. The effect of disease on populations of wild animals has not been so closely studied; but its importance is well known to many ecologists and others. In a mimeographed paper recently issued by the Food and Agriculture Organization (McDiarmid, A., "Diseases of Free-living Wild Animals". Pp. 91. Animal Health Branch Monograph No. 1. F.A.O., Rome, 1960), Dr. McDiarmid summarizes the information available about the diseases of wild animals and lists the recent literature up to 1955. The diseases are classified as those due to bacteria, fungi, viruses, protozoa, rickettsiae, and neoplasms and tumours, and the author gives a brief review of what is known about each together with references to the literature. The paper is issued as a Food and Agriculture Organization "Working Paper" for circulation to veterinarians and others in the Organization interested in the subject. It is to be hoped that it may be made available also to the many workers outside the Organization who will find it an extremely useful work of reference.

Pre-History: Implements and Rock-Carvings

THE July issue of *Man* contains several articles of general interest. The mystery of A. C. Carlyle and his collections from caves in the Morhana Pahar district of India has been elucidated by G. de G. Sieveking of the British Museum. It seems that many of the finds were bought by Dr. Sturge and are now in that celebrated collection at Bloomsbury. A. D. Lacaille illustrates a number of very large British Acheulean coups de poing, and a puzzling rock-carving from the Val Camonica is discussed by Dr. Anati of Paris. The site is near where the great glacial valley debouches on to the north Italian plain, and many rock-carvings there have been known for a long time. They include animals and humans treated in a conventional manner somewhat recalling the Copper Age paintings of Las Figuras in south-west Spain. The little group in question seems to indicate either a phallic or a ritual scene. The author suggests a date for this art group somewhere towards the start of the first millennium B.C. Is not this somewhat too early? An interesting illustrated article on the Hainault scythe in England by G. E. Fussell and another on the ethnic origins of Zande office-holders are also included.

Royal Meteorological Society:

Scientific Activities Fund

GRANTS from this Fund are intended to be used to assist attendance at meteorological conferences, and priority will be given to members of the Royal Meteorological Society. Applications from younger meteorologists will receive special consideration in order to give them the opportunity to present their work. Assistance may also be given in furtherance of meteorological research, or in support of a personal meteorological activity. Grants may also be made to European meteorologists who have been invited by the Society to visit Britain to give lectures or courses of lectures, or British meteorologists who have been invited to visit Europe for the same purpose. Applications, which should include details of estimated

expenditure, should be forwarded to the Assistant Secretary (Scientific Activities Fund Committee), Royal Meteorological Society, 49 Cromwell Road, London, S.W.7, not later than December 15, 1960.

Announcements

THE Charles Léopold Mayer Prize for 1960 of the Société de Chimie Biologique has been divided between Prof. R. Monier, Maître de Conférences de Chimie Biologique at the Faculté des Sciences de Marseille, and Dr. M. Beljanski, maître de recherches at the Centre National de la Recherche Scientifique, for their work on nucleic acids and nucleoproteins. The Prize, which is awarded annually, has a value of 5,000 NF.

THE Palaeontological Association is holding a discussion meeting on "Palaeo-ecology" at the Department of Geology, the University of Glasgow, during December 16-17. Further information can be obtained from the Secretary to the Association, Dr. Gwyn Thomas, Department of Geology, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7.

COMMENCING on January 14, 1961, Norwood Technical College is holding a course of twelve morning lectures and appropriate practical work as "An Introduction to Micro- and Semi-microchemical Methods". This course is particularly suitable for teachers, industrial and research chemists and is designed to survey the principal branches of chemistry in which small-scale methods have been successfully applied. Further information can be obtained from the head of the Chemistry Department, M. A. Fill, Norwood Technical College, Knights' Hill, West Norwood, S.E.27.

THE Bradford Chemical Society, the Plastics Institute (Yorkshire Section) and the Department of Chemical Technology of the Bradford Institute of Technology, in conjunction with the Yorkshire Council for Further Education, are jointly holding a symposium on "New Developments in Plastics" at the Bradford Institute of Technology on February 11, 1961. Further information can be obtained from the honorary secretary of the Bradford Chemical Society, R. P. Sheldon, Bradford Institute of Technology, Great Horton Road, Bradford 7.

THE University of Cambridge Physical Chemistry Summer School will be held again in 1961, during August 12-19, the general topic being "Fast Reactions". Further information can be obtained from Prof. R. G. W. Norrish, Department of Physical Chemistry, University of Cambridge.

THE first international conference on "Protozoology", organized under the auspices of the Czechoslovak Academy of Sciences, will be held jointly with the thirteenth meeting of the Society of Protozoologists in Prague during August 22-30, 1961. Further information can be obtained from Dr. Norman D. Levine, College of Veterinary Medicine, University of Illinois, Urbana, Illinois (not later than March 1), or Prof. Otto Jirovec, Charles University, Vinicna 7, Prague 11 (not later than April 1).

ERRATUM: In the communication entitled "Prolonged Survival of Human Sperm in chemically defined Media at Room Temperatures", in *Nature* of November 26, p. 760, it is stated that the pH of the medium was initially 7.1; this should read 7.4.

THE BRITISH ASTRONOMICAL ASSOCIATION

WORK OF THE RADIO-ELECTRONICS SECTION

IN January 1957 the British Astronomical Association formed a Radio-Electronics Section. Such a move was quite consistent with the Association's interest in all branches of astronomy. Since the fortunes of the amateur astronomer have always been of interest to the professional scientist because of the successes that amateurs have had in astronomical research, it would seem that the time is ripe for a statement on the work of this new Section and its contribution to amateur endeavours.

The great stimulus to the Section's activities was the launching of the first Soviet Earth satellite. Its members made both visual and radio observations of *Sputnik 1* and *Sputnik 2* which have been reported elsewhere¹. Since then, in co-operation with the Radio Research Station (Department of Scientific and Industrial Research), an independent service has fed sixty visual observers with predictions in order to stimulate observations. Visual observations of Earth satellites are most necessary if a satisfactory prediction service is to be maintained. They are also an example of the usefulness of the amateur observer. Of recent months it has become necessary to constitute a subsection to deal with this new but major field of amateur activity. This revised policy has also caused a complete revision of the memoir on Earth satellites² which is to be published at the end of the year. In addition to the history of the radio observations, it will now include full details of visual observing methods, a summary of prediction methods derived from G. E. Taylor's work³ and a generalization of prediction techniques (as yet unpublished) suitable for application to all future satellites, due to K. Fea.

Earth satellites were not intended to be the main activity of the Section. They have, however, taken up a large part of the time devoted to amateur radio astronomical activities during the past three years, and account perhaps for the not very spectacular developments in the field of amateur radio astronomy.

Nevertheless, sufficient data have been collected by members of the Section to merit a recommendation for the publication of a memoir devoted to the design, construction and operation of radio telescopes. An interesting contribution by two of the contributors contains an approach to the design of large radio telescopes; it is a combination of existing papers by Lovell⁴, Husband⁵ and Christiansen⁶, but it is thought to be a more comprehensive introduction to the mechanical, electrical and radio astronomical research problems involved⁷.

However, at the real level of amateur research, the corner-reflector type of aerial as typically described by Carr⁸ for use at low frequencies has been modified, and, although of smaller dimensions, is steerable in altitude. Such aerials can be built at relatively low costs and are suitable for use as the aerial sections of low-frequency interferometers. F. W. Hyde has successfully operated a phase-switching interferometer using these aerials at 27 Mc./s. with a space of

20 wave-lengths. Other similar instruments have been operated at 50 and 36 Mc./s. Experiments are now being conducted with corner V reflectors and also large arrays of dipoles in the region of 19 Mc./s.

These experiments were initiated from a suggestion by Dr. A. Hewish, of Cambridge. He suggested that simple instruments such as these could be used to extend his own work in investigating the solar corona into the low-frequency region of the electromagnetic spectrum⁹. With the narrow spacings of the interferometer aerials, a longer period of observation is necessary to provide satisfactory results for separating the radiations of the Crab Nebula from those of the Sun, the two components being well integrated on the records. A year's continuous observations have been made at 27 Mc./s., and the operation of the instruments is now reasonably well understood. The preliminary results of these investigations suggest that useful work can be done in this low-frequency part of the electromagnetic spectrum, and the rough analysis of the observations made during the 1959 and 1960 occultations suggest a confirmation of Hewish's theory.

However, by far the most important factor has been the realization that with a network of similar interferometers operating at widely scattered points throughout the British Isles and operating on the same frequency it should be possible to assess the accuracy with which observations can be made in the low-frequency region. With each station providing similar observations, evaluations of the influence of the ionosphere and the true value of conducting research at the lower frequencies where the ionosphere plays such an important part in reception can be made. Two stations, at Beckford (Gloucestershire) and Clacton-on-Sea, are operating simultaneously on 27 Mc./s., and it is planned to build instruments operating in the region of 19 Mc./s. at both these sites.

In addition to the observations of the solar corona and the qualitative analysis of the effects of the ionosphere, it is intended to use these instruments in attempted observations of the non-thermal radiations from Jupiter. These observations will extend the information available on the continuity of storms through consecutive rotations of the planet, and since the same group of stations will be available for such observations further light should be thrown on the terrestrial ionospheric features of the emissions associated with this planet, which have been discussed by Gardner and Shain¹⁰, and more recently in *Nature* by A. G. Smith *et al.*¹¹.

Apart from encouraging the beginner to construct simple radiometers for observing deflexions in the output as the aerial is pointed to Cygnus, Cassiopeia and the Sun, the Section has undertaken an unusual education programme. A portable radio interferometer operating at 200 Mc./s. (ref. 12) was designed for erection in school playgrounds. Lectures have been given to groups of schools, and several younger

members of Advanced Level (General Certificate of Education) standard have studied the history and techniques. The most interesting project has been in connexion with a project for sixth-formers. Two sixth-formers of the Salesian College, Battersea, with no previous knowledge of radio astronomy, were set a three-part project. The first part dealt with fundamentals, the second part with a simple practical project and the third was a dissertation on the two parts of the project followed by an oral examination. The boys were given only the minimum of information, and at the time of writing the first part of the work had been completed. The indications are that their work will throw considerable light on the value of project work with oral examinations being included among the methods of university selection.

Although the Radio-Electronics Section cannot possibly compete with the professional radio astronomers, it is clear that there are a number of small but valuable research projects which they can perform. The time taken for the completion of the project is admittedly long.

The other asset of the educational policy of the Section is that it has enabled a number of people to come into contact with the practice of the science and others to gain their first contact with this new science. These are important factors in a science where professionals are few and far between.

The financial support given by the Carnegie Trust, the Council of the British Astronomical Association and the encouragement of the professional radio astronomers, and of the Department of Telecommunication, Norwood Technical College, seem to justify the aims which the Section has set itself. These are aims which undertake a new responsibility for amateur science; the provision of a new type of link between the scientist and the public: the provision of a liberalization for science in its increasing specialization—a liberalization that reminds people that in all the complexity of modern technological thinking it is still possible for an outsider in his own time and at his own inclination to come to grips with the mysteries of the universe.

THE TWENTY-FIRST INTERNATIONAL GEOLOGICAL CONGRESS

THE twenty-first International Geological Congress was held this year in the Nordic countries, with excursions in Denmark, Finland, Iceland, Norway and Sweden, and with meetings in Copenhagen during August 15–25. The usual excursions were in three groups: those preceding the actual meetings in Copenhagen; one-day excursions during the meetings; and longer excursions afterwards, some of which ended in mid-September. The number of geologists participating was about 2,500, coming from about a hundred various countries.

Although the possibility had been touched on in 1952, in Algiers, it was not until the 1956 meeting in Mexico that the invitation to geologists of the world to hold the Congress in the Scandinavian countries in 1960 was brought forward. After the invitation had been accepted, an organizing committee of the Congress was appointed by the geologists of the five countries. Its composition was as follows: Denmark, Arne Noe-Nygaard, Theodor Sorgenfrei and Christian Poulsen; Finland, A. Laitakari, P. Haapala, V. Marmo and H. Ignatius; Iceland, S. Thorarinnsson, T. Tryggvason and G. Kjartansson; Norway, O. Holtedahl, T. F. W. Barth and J. A. Dons; Sweden, K. A. Lindbergson, N. H. Magnusson, F. E. Wiikmann and E. Fromm. During the preparation period the organizing committee met from time to time in the different countries; at shorter intervals executive secretaries from each country came together (Dons, Fromm, Ignatius and Sorgenfrei). It does not minimize the efforts of the members of the organizing committee as a whole that the splendid work carried out by Dr. Sorgenfrei, on whose shoulders the heaviest burdens fell, is specifically underlined.

Of the excursions primarily offered, a few had to be cancelled for various reasons. The total number of guide booklets worked out was 42, amounting to more than 1,500 pages. As is usually the case, a considerable number of pre-session excursions were repeated as post-session tours. Of the guide booklets, Denmark was responsible for 6, Finland 6, Iceland 1, Norway 17 and Sweden 12. The seventy excursions covered an area between Iceland in the west and eastern Finland in the east, and between southern Denmark in the south and Spitsbergen in the north. The subjects covered by the various tours extended from recent volcanism and hot-spring activity in Iceland to Caledonian orogeny in Norway, from the Pre-Cambrian of Sweden and Finland to the Cretaceous and Tertiary sediments in Denmark.

The formal meeting of the Congress in Copenhagen was held under the patronage of H.M. King Frederik of Denmark. The first meeting of the Council was held on August 15. The opening of the General Assembly took place on August 16 in KB-hallen. Señor García Rojas, president of the Twentieth International Geological Congress in Mexico first spoke; then the assembly was addressed by the Danish Prime Minister, Mr. Viggo Kampmann, and finally the newly elected president, Prof. Arne Noe-Nygaard, took the chair.

The following subjects had been selected for presentation and discussion, each subject corresponding to a section of the Congress: (1) geochemical cycles; (2) geological results of applied geochemistry and geophysics; (3) Pre-Quaternary absolute age determination; (4) chronology and climatology of the Quaternary; (5) the Cretaceous-Tertiary bound-

dary; (6) Pre-Quaternary micropalaeontology; (7) Ordovician and Silurian stratigraphy and correlations; (8) Late Pre-Cambrian and Cambrian stratigraphy; (9) Pre-Cambrian stratigraphy and correlations; (10) submarine geology; (11) regional and structural problems in oil geology; (12) regional palaeogeography; (13) petrographic provinces, igneous and metamorphic rocks; (14) the granite-gneiss problem; (15) genetic problems of uranium and thorium deposits; (16) genetic problems of ores; (17) minerals and the genesis of pegmatites; (18) structure of the Earth's crust and deformation of rocks; (19) Caledonian orogeny; (20) applied geology; (21) other subjects.

As a new feature in the arrangement of the meeting, it may be mentioned that all papers selected for presentation were printed prior to the sectional meetings and delivered to the participants on their arrival—more than 4,000 pages.

During the meeting, the following affiliated associations and societies held meetings: International Palaeontological Union, Association of Sedimentary Geologists, International Association of Hydrogeologists, International Mineralogical Association, Association des Services Géologiques Africains, Society of Economic Geologists, International Commission for the Study of Clays. A joint symposium was arranged by the Geochemical Society and the Geochemical Commission of the International Union of Pure and Applied Chemistry. The Karpatobalkan Association also held meetings.

The following commissions of the International Geological Congress held meetings and reported to the General Assembly on the business meeting of the Congress on August 23: (a) International Commission on Stratigraphy, with several sub-commissions (Prof. R. C. Moore resigned, and a nominating committee for electing new officers was appointed with Dr. C. J. Stubblefield as chairman); the Commission to be continued. (b) Commission of the Geological Map of Europe (Prof. A. Benz and v. Gaertner); the Commission to be continued. (c) Commission of the Geological Map of the World, with two sub-commissions (Prof. M. F. Blondel); the Commission to be continued. (d) Commission on the Gondwana System (Dr. S. H. Haughton); it was suggested that this Commission be made a sub-commission to the Commission of Stratigraphy (a) with four members, one from each of the following regions: South Africa, South America, Australia and India. (e) Commission on Meteorites (report by the secretary, Dr. M. H. Hey); Commission to be continued; Prof. E. L. Krinow was elected as the new president. (f) Commission for the Formation of an International Geo-

logical Abstracting Service (Dr. H. M. E. Schurmann); first number of a geological abstracting journal will be issued in the beginning of 1961 by Pergamon Press. (g) Commission de la Croûte Terrestre (Prof. C. E. Wegmann and Prof. P. Fourmarier); it was proposed that the existing Commission be discontinued and that its functions concerning the establishment of a lexicon of tectonic terms handed over to the sub-commission on the tectonic map of the world (under c above) and that a new organization be formed under the title, "Commission de Co-ordination des Recherches Géologiques et Géophysiques", with Prof. J. Goguel as president. (h) Commission for the Spenidarov Prize; members elected and functioning during the twenty-first session were the following: D. V. Nalivkin, J. M. Harrison, V. Marmo, M. Roubault and Th. Sorgenfrei.

During the meetings an exhibition of geological maps, instruments and books was arranged in an exhibition building near the main site of the Congress. The Mineralogical and Geological Museum of the University of Copenhagen, also situated near the main site, was open daily during the period; more than 3,000 visitors passed the main door during the ten days.

At meetings of the Council of the Congress, traditional questions were treated in a traditional manner. Special treatment was given to the question of the formation of a Geological Union, which was prepared by the Bureau of the Congress before being presented to the Council for decision. The Council decided at its business meeting on August 23 to appoint an organizing committee for the formation of an International Geological Union. It was further decided that the organizing committee should prepare draft statutes of the Union in order to get it established in 1961. This committee consists of the following members: N. Belyaevsky (U.S.S.R.), W. Smulikowski (Poland), B. C. Roy (India), J. M. Harrison (Canada), T. B. Nolan (U.S.A.), L. Hawkes (United Kingdom), R. Laffitte (France), E. Clar (Austria), H. M. E. Schurmann (Netherlands), K. A. Lindbergson (Sweden), V. Marmo (Finland), A. Noe-Nygaard (Denmark), J. A. Dons (Norway) and T. Sorgenfrei (Denmark).

At the closing meeting of the General Assembly on August 25, Dr. Sigurdur Thorarinsson, of Reykjavik, was awarded the Spenidarov Prize for his outstanding volcanological and tephrochronological studies in Iceland. Then representatives of former host countries greeted the Congress, and Dr. Roy, from India, looked forward to seeing members in 1964, at the twenty-second Congress, in his country.

ARNE NOE-NYGAARD

POLLINATION BY INSECTS

"POLLINATION" was the subject of a symposium held during August 12-14 at Copenhagen prior to the eleventh International Congress of Entomology in Vienna. The symposium was presided over by Prof. Eric Åkerberg of the Swedish Seed Association, and the final sessions took place at the Association's plant breeding station at Svalof.

The importance of bees as insect pollinators has long been recognized in the production of fruit and seeds of insect-pollinated plant species, and it was therefore natural that the majority of papers were

concerned with bees. In the seed production of red clover, it was clear that humble bees were useful pollinators in every country, but the value of honey bees varied from country to country. The special difficulties of obtaining satisfactory seed yields from tetraploid red clover, however, appeared to be due as much to abnormal pollen as to the lack of suitable pollinators.

Several speakers reported work on the habits of humble bees, and various attempts to increase the population of the humble bee were described. Danish

workers reported that certain species of humble bee had now been kept in domestication for several years, and this had enabled a much more detailed investigation of their breeding habits than had formerly been possible.

The use of 'scent direction' to improve the value of honey bees as pollinators was discussed by several contributors, but results had been somewhat varied, and it was evident that further work on this important subject is needed. Attention was directed to the varying composition of nectar between the different plant species, and the possibility that this might influence pollination was discussed. The pollination of lucerne, the subject of another session, was covered by papers describing work on this subject in North America.

At the closing session of the symposium, the following conclusions were agreed.

(1) An annual census of bumble bees would be desirable in order to identify trends in populations that could be associated with changing agricultural practices.

(2) Solution of the seed production problem in tetraploid red clover will require continued effort by plant breeders, pollination specialists and biologists.

(3) Greater effort should be given to obtaining a better understanding of the basic relationship between pollinators and flower. Identification of morphological or physiological links in those species of bees having a restricted host-range would be worth while.

(4) Pollination should be considered as one of a number of factors, and consideration should be given to them all when studying seed production. Increased effort should be given to domestication of bumble-bees. However, much more basic information needs to be developed before the full potential of this endeavour can be realized.

(5) Exchange of pollinators between countries should be encouraged. An effort should be made to provide the proper pollinator for a given crop. This can be done by growing the crop where pollination occurs naturally, or by providing the pollinator where it does not occur naturally. A survey of all known pollinating insects for clover and alfalfa is required.

(6) Honey bees should be exploited to the maximum extent possible. Information concerning this pollinator is greater than for any of the others, and should be utilized.

(7) Scent training should be studied further; but identification of the volatile products in flowers would seem to be necessary in order to advance this phase of the work.

These recommendations, with the papers read at the symposium, are to be published in due course. The secretary of the symposium was Dr. Ole Hammer, assisted by Dr. Tom Mittler, Statens Biavlfsorsøg, Strødam, Hillerød, Denmark.

R. P. HAWKINS
M. S. PERCIVAL

GENERATION AND APPLICATION OF ELECTROSTATIC POWER

AN international colloquium, held under the auspices of the Centre National de la Recherche Scientifique, was held at Grenoble during September 24–October 1. The subjects discussed covered the generation of electrical power by electrostatic means and the applications of these machines. It is believed to have been the first international conference devoted entirely to the science of electrostatics. Due to the presence of Prof. N. J. Felici, who is the holder of the chair of electrostatics at the University of Grenoble, this was a natural meeting place, and more than 120 engineers and physicists gathered there.

Appropriately, after a description of the early days of electrostatic machines in Grenoble, given by Prof. L. Néel, the lectures were inaugurated by Prof. Felici's discussion of the types of electrostatic generator and his hopes for the next 'generation' of electrostatic machines. This, in conjunction with a talk by Prof. J. G. Trump of the Massachusetts Institute of Technology, indicated in broad outline the scope of present possibilities and the problems of the future. There were two types of electrostatic generator in current use: first, the Van de Graaff belt-type machine, and secondly, the Felici insulating transporter cylindrical machine. Both have their advantages and disadvantages. Briefly, for high voltages and very low currents the Van de Graaff is better, and for low voltages (below one million volts) and higher currents (up to 50 m.amp.) the Felici machines are better. For long-term continuous running, the cylinder machine is undoubtedly more reliable, but in its present state of development it cannot provide the very high voltages or current

that may be required. Prof. Trump discussed also a further type of electrostatic generator, the disk machine. This is by no means a new development; and on show at the colloquium was a very early disk-type generator built in the late 1940's at Grenoble. However, it seems to be generally agreed that this type of design has the greatest development possibilities, particularly for space travel, where the problem of insulation is much reduced.

Several papers were presented which discussed the application of this type of electrostatic generator for ion propulsion. Considerable research is being carried out both in France and the United States on electrostatic machines for this purpose. The design of a generator delivering 1,250 kW. at 200 kV. is being investigated at the High Voltage Engineering Corporation in Massachusetts. Parallel work is proceeding in France.

The future development of the cylinder machine is being investigated to increase the currents available, and other dielectrics, including various liquids, are being studied. Questioning elicited visualized requirements in the region from 100 kV. at 100 m.amp. to 1 MeV. at 1 amp., but no concrete suggestions as to how this might be achieved were agreed. The emphasis on ion engines for space travel was supplemented by a talk on electrohydrodynamic energy conversion by a representative of the U.S. Air Force.

Engineers who have been involved in the practical problems of designing the Felici generators and producing a standard range of models for industry gave a fascinating insight into the complexities of electrostatics as opposed to the comparative simplicity

of electromagnetic machines, despite the duality which exists between them. There is no doubt that the shortage of technology on this subject is retarding the advance of the electrostatic machines. Nevertheless, an impressive array of standard machines were described, and on a subsequent visit to the factory of Société Anonyme de Machines Électrostatiques in Grenoble the members of the colloquium were able to see the ideas of Prof. Felici in concrete form. From the smallest machines for electrostatic deposition of paint to the large 600-kV. and 1-MeV. generators for accelerators and other nuclear applications, one cannot help but be impressed by the progress of this technique. When it is realized that the continuous operation of these generators for thousands of hours with negligible maintenance is regarded as commonplace, an appreciation of the status of the technique is possible.

Of particular interest on the nuclear side were the neutron generators capable of delivering fluxes of neutrons up to 10^{11} neutrons per sec. Continuous development aimed at greater fluxes with smaller machines is being carried out.

To sum up, the position of the electrostatic generators at the present time is not easy. Both the French and American experts expressed faith that the present machines are the first in a field capable of great development. Discussion gave glimpses of actual development models in course of construction at the present time. Whether certain fundamental difficulties will obstruct this advance or whether new techniques will emerge remains to be seen. Whatever happens, great resources of money and labour will have to be made available.

The remainder of the lectures dealt with the applications of electrostatic machines. Two very interesting papers were read, one by Dr. W. D. Allen (Atomic Energy Research Establishment, Harwell) and the other by Mr. F. A. Julian (Atomic Weapons Research Establishment, Aldermaston). They described the remarkable achievements of the staff of the United Kingdom Atomic Energy Authority in constructing two 12-MeV. tandem accelerators which have now been in operation for the past year. The many problems which they encountered and overcame were discussed and a résumé of the experimental work carried out, both in the design of the machines and their subsequent usage, were given.

In the more commercial field of precipitation and mineral separation, the use of electrostatic generators has, as yet, had little application apart from the deposition of paint. Demonstrations of the paint precipitation plant show the fascinating possibilities of electrostatic machines in industry. The 100-kV. unit is very small, approximately 24 in. long, 9 in. wide and 9 in. high, and completely safe. The operator may place his finger on the high-voltage terminal of the spray gun and feel very little effect. The generator is very light and easily portable. Being sealed in a high-pressure cylinder, it is impervious to all dirt and damp.

For other heavier precipitation processes, the electrostatic machine, so far, does not yet deliver sufficient current. Considerable research is going on in the United States in mineral separation, and, in Europe, on insecticidal spraying in agriculture.

Future applications in the nuclear field would appear to lie with neutron sources of higher fluxes than at present available. If fluxes of the order of 10^{12} – 10^{14} neutrons per sec. could be produced economically, there would be a demand from those at present forced to use reactors for activation experiments. There is some argument as to what an economic figure might be, but there is a real hope that for an accelerator working at, say, 1 MeV., 4 m.amp. of ions in the beam of a beryllium target could produce a flux of 10^{12} neutrons per sec. From preliminary inspection it was severally agreed that the price of such a machine might be very attractive *vis-à-vis* a small reactor. A 1-MeV. accelerator and a high-current ion-source of this type was shown to the members of the colloquium.

Both Prof. Trump and Prof. Felici touched on the possibility of power generation by electrostatic means. It may seem inconceivable that the electromagnetic power generators could be superseded by electrostatic methods for the generation of electric power for the grid system. However, a strong plea by Prof. Felici for research funds to be made available throughout the world for work in this direction was made. Prof. Felici cited the considerable advances achieved so far in the U.S.S.R., and the United States. Perhaps the domination of the present technology has blinded engineers to the possibilities in this other field.

BRITISH BOOKS AND PERIODICALS FOR USE OVERSEAS

IN a written answer to questions in the House of Commons on November 7 about Government Information Services, the Chancellor of the Duchy of Lancaster, Dr. C. Hill, made a long statement about the low-priced book scheme. The first group of 23 text-books on scientific, engineering and other technological subjects, he said, is now being produced, and the books should be available during the forthcoming buying season to students and others in India at 9s., 12s. or 15s. a volume, depending on size, diagrams, illustrations, etc. It was expected to discuss shortly with the Pakistan authorities the possibility of operating a similar scheme for that country.

Dr. Hill gave a list of the titles which had been approved by the Advisory Committee, following

consultation with the university authorities in India. The list involved more than 100,000 volumes and more copies would be produced as necessary. A further group of university text-books on these and other subjects would follow. The Advisory Committee has also recommended further categories of books, similarly aimed at helping to meet the needs of readers in developing countries in Asia and Africa. One group of titles included would help people in these countries who wished to develop their knowledge of English, or to extend their practical skills, and these volumes would be available in substantially larger numbers and at much lower prices than the university text-books. The Advisory Committee recognizes that some of its other recommendations involve books which need bringing up to date or

other adaptation and that this work requires detailed and expert study. The Publishers' Association has now recommended to its membership the establishment of a consortium of publishers familiar with the export fields concerned or otherwise interested in the low-priced book scheme, which would pool the experience and resources of the trade in Britain and, in co-operation with local trade interests overseas, might further assist the Government's programme.

Dr. Hill also stated that an encouraging increase in the flow of British publications into Yugoslavia has occurred since the agreement with the Yugoslav Government was announced on April 14, and that the text of an agreement with the Israeli Government, providing for imports up to £400,000 a year of British books, periodicals, newspapers and certain kinds of gramophone records, was laid before the House on October 25. The Government of Indonesia is considering British proposals for an agreement to facilitate the import of British publications, and steps have been taken to overcome the difficulty arising from the system of import control used in Chile, which has led to an unsatisfied demand there

for British books. The British Council has undertaken a considerable extension of its library services, and of the half-million books distributed by the Council in the past 18 months to its own libraries or other institutions all over the world, by far the greatest number have gone to Africa and Asia, especially to India, Pakistan and Ceylon. The range of learned periodicals covered by these libraries has also been greatly extended and many more presentations have been made to institutions such as medical schools.

In India and Pakistan, the Council's multiple holdings of widely used text-books has been very greatly increased, and in the past four months some 45 Indian universities and colleges have begun to use this scheme; the Council's services in these countries have also been improved by recruitment of a number of professional librarians to advise locally on the choice and direction of material and to organize the reference use of the libraries. Important presentations of books and periodicals have been made to colleges and other institutions in Nigeria, Ceylon, Burma, Viet Nam, Malaya and Indonesia.

THE POST OFFICE RESEARCH STATION

SOME of the scientific and engineering work of the Post Office Research Station at Dollis Hill, London, was shown during its open days, September 22-23. This Research Station serves the telephone and radio systems of the British Post Office, and also works on the mechanization of the postal service.

The Post Office (in collaboration with the National Physical Laboratory and the Royal Observatory) broadcasts signals of standard time-interval and frequency, having precisions of the order of ± 2 parts in 10^{10} . This has required the production of quartz crystals of great precision and stability, and the development of techniques for mounting them and maintaining them in oscillation at constant temperature. Further improvement in these time and frequency standards may require the use of cesium-beam resonators, one of which was shown working.

Transmission along wave-guides at frequencies such as 35,000 Mc./s. is a possible method of long-distance communication. The intended mode of transmission is H_{01} ; all others must be suppressed since they have different velocities of propagation. Suppression can be achieved either by using for the wave-guide a close-wound helix, so that its longitudinal resistance is high, or by internal coating of a solid guide with a dielectric other than air. The first of these methods is being investigated by other workers; the Post Office is studying the use of dielectric coatings.

Parametric amplifiers operate through the variation of the electrical magnitude of some component by means of a local source of power—the 'pump'. They are particularly useful at frequencies greater than about 200 Mc./s. A parametric amplifier was shown working, based on a variable-capacitance diode, and suitable for a tropospheric-scatter system working at about 900 Mc./s.; a similar amplifier, for 960 Mc./s., had been used to receive signals from the United States by way of the balloon satellite *Echo I*.

For some years the Post Office has specialized in work on metallic magnetic materials. Samples of silicon-iron were shown in which special crystalline textures had been produced by suitable rolling and heat treatment. Methods shown for work on magnetic properties included measurement of saturation flux by reversal of the specimen itself in a stationary field—a method suggested by Ewing and apparently overlooked since his time—and an apparatus displaying the variation of magnetization with direction in anisotropic material.

For many purposes the Post Office is introducing transistors into its apparatus, but, as its need for reliability is unusually strict, it is interested in the probable life of transistors and in the causes of their premature failure. One investigation of this kind has led to the detection of leakage through seals, even when the leakage-rate is of the order of 10^{-11} litre micron per second. Improvements in thermionic valves are still being pursued, however, and gains in both performance and reliability have been achieved: a valve suitable for submarine cable systems, having a conductance of 25 mA./V., yet operating at only 40-50 V. high tension, has been produced by winding both control grid and screen grid on a single former.

The chemical laboratories have produced a range of organic phosphors, intended for making code markings in postal sorting work. They are based on cyanuric-acid-formaldehyde condensation compounds, and offer a wide range of colours. They are easily handled and can be incorporated into printing inks and other such media.

The influence of high-speed computers as an aid to physical and engineering research was clearly in evidence. Although the Research Station has no computer of its own, it hires time on other computers and has its own staff who can prepare computer programmes.

A. C. LYNCH

BIFURCATION AND OTHER IRREGULARITIES OF THE IONOSPHERIC F2-LAYER

By DR. E. WOYK (CHVOJKOVÁ)

Astronomical Institute, Czechoslovak Academy of Sciences, Praha 12

IN recent years the bifurcation and other irregularities of the ionospheric F2-layer have been much discussed. I have made several attempts to provide a theoretical basis of the subject, and finally I derived formula (2), which expresses the diurnal variation of the critical frequency of the F2-layer¹. Incidentally, the subject is of interest in astronautics; thus the usual sort of short-wave connexion would fail on account of rareness of a planetary atmosphere preventing a pronounced maximum of electron density above the surface, so that only a local minimum of electron density—arising from the process of bifurcation—can permit the circum-planetary propagation shown in ref. 3.

My theory of bifurcation is explained in a few words as follows: the excess of energy of each ionizing photon over the ionizing potential is transformed into heat. Thus, on account of the quasi-neutrality, the rarefaction of the gas at the maximum of ionization can create a small secondary minimum of electron density there which separates the F-layer into F1 and F2. This secondary minimum of electron density N appears paradoxically just at the maximum of electron production q (Fig. 1a, b).

It was deduced that a layer arising from a previously un-ionized gas cannot be divided into two parts with the exception of a very rare atmosphere

($n \leq 10^{10} \text{ cm}^{-3}$) and only when the temperature T_m at the maximum of ionization is at least twice as high as the temperature T_0 at the beginning of ionization. If at sunrise, however, the new ionization begins to act on a region where a considerable quantity of free electrons has remained from the previous day, it is possible that the bifurcation is produced even beyond the given limits, as shown in Fig. 1c. It appears, however, that only the F-layer can be separated, never the H-layer.

Also the strange diurnal and seasonal variation of the critical frequency f_c of the F-layer and its unexpected dependence on solar activity (Fig. 2) can be explained on my theory as follows²: the diurnal variation of $f_c F2$ cannot be expressed by a simple sinusoid as is the case of $f_c H$. It seems rather to follow a sinusoid the period of which increases linearly with time ($T = At + B$). See the auxiliary dotted curve of Fig. 2 which is expressed by:

$$\bar{f}(t) \equiv \bar{f} = c + M \left(1 - \cos \frac{2\pi t}{24a + (1-a)t} \right),$$

$$a = \frac{T_1}{24 - T_1} \quad (1)$$

From this curve a cosinusoid was subtracted in order to take into account the rarefaction produced by ionization (Fig. 2, full curve). It was surprising to find that this cosinusoid would have to be subtracted from $\bar{f}(t)$ even after sunset, when the real course of $f_c F2$ had to be expressed precisely. It seems that the atmosphere, expanded during sunshine and contracting at sunset, passes over the equilibrium, oscillating about the equilibrium density with the same period as it had during daylight. Thus the resulting formula, capable of expressing any diurnal course of $f_c F2$, is:

$$f_c F2 = \bar{f} \left[1 - m \left(1 - \cos \frac{2\pi(t - t_1)}{\tau} \right) \right] \quad (2)$$

The beginning of curve (2) is given by a value t_0 not differing much from that at sunrise. The time t_1 at which the oscillation starts to be subtracted need not be zero; moreover, t_1 varies with solar activity R and it is the variation of t_1 which makes it possible to express the strange variation of the $f_c F2$ -curves with R . It is to be noted that a small increase of t_1 transforms the first curve of Fig. 2 ($R = 0$ usually characterized by a flat and late maximum) into the curve corresponding to $R = 150$ (characterized by a sharp maximum appearing just before midday). The coincidence of the theoretical curves (2) and the real ones (measured at different epochs and different points of the Earth) is further evidence for this theory of bifurcation of the F2-layer by photo-ionization. A prediction frame⁴ has been constructed for satellite and telecommunication purposes, and formulae for trajectories⁵. By the use of this frame,

Fig. 1. Distribution with height: (a) the electron production q according to equation (4); (b) the corresponding electron density N of equation (5) allowing for no remainder of free electrons at the beginning; (c) allowing for a sunrise-remainder of free electrons (shown by the dotted curve)

Fig. 2. Diurnal course of the critical frequency $f_c F2$ at middle latitudes in winter for low and high solar activity R and the explanation of symbols used in equations (1) and (2). All parameters have a fundamental physical meaning. The plotted curves are defined by $t_s = 6.0$ hr., $c = 8.2 + 0.009 R$ (Mc/s.), $a = 0.80$, $M = 1.7 + 0.022 R$, $t_i = +0.1 + 0.008 R$, $\tau = 10.0$ hr., $m = 0.12$. (m depends upon latitude only; the other parameters depend also on season)

it is possible to determine easily the elements of trajectories of satellites in spite of differences in time and position. Also, on planets with a highly curved surface and a very rare atmosphere, short-wave communication would depend on whether a negligible rarefaction of electron density above the surface will allow circum-planetary propagation, analysed in ref. 3, or not.

Let us treat a relatively cold atmosphere of temperature T_0 , containing only one sort of particles, on which suddenly a source of powerful radiation $h\nu$ begins to act. The mean temperature T_i of a recently ionized pair of particles follows from the mean energy

of the ionizing photon $h\nu = E_i + \frac{3}{2}kT_i$, where E_i

is the energy necessary for ionization. Neglecting recombination, we find that, after a relaxation time t , the tq newly ionized particles of temperature T_i mixed with the n particles of the neutral remainder of gas (having the temperature T_0) give the resulting gas temperature T :

$$T = \frac{T_0(1 + az)}{1 + tq/n} \approx T_0(1 + az) \quad a = \frac{T_i t q_0}{T_0 n} \quad z = \frac{q}{q_0} \leq 1 \quad (3)$$

From the gas distribution with height, $n = n_0 \exp(-h/H)$ and the intensity of radiation at a height h given by $dI = A I n \sec \zeta dh$, we find the course of ion-production with h near $q_{\max}$ (where $dq/dh \approx 0$):

$$q = q_m \exp(1 - x - \sec \zeta \exp(-x))$$

$$x = \frac{1}{H_0} \frac{h - h_m}{1 + az} \quad q_m = \frac{q_0}{1 + az} \quad (4)$$

which is identical with the well-known Chapman formula⁶ (where $T = T_0 = \text{constant}$), except that the electron production q is now T/T_0 times rarer and the layer is T/T_0 times larger. The thin curve of Fig. 1a represents the Chapman layer, the thick one relates to equation (4) for the case in which the maximum T_m is three times T_0 .

After a relaxation time t , we suppose that the ionization equilibrium is accomplished, and we put $dN/dt = 0$ into $dN/dt = q - \alpha N^2$, which gives $N_0 = (q_0/\alpha)^{1/2}$. The suffixes here denote values at which the increase in temperature has not yet been taken into account. From the relations $N_0 T_0 = N T$, $\alpha \sim T^j$ and equation (3), the equation for electron distribution with height is obtained (Fig. 1b):

$$N = \sqrt{\frac{q_0}{\alpha_0}} z^{1/2} (1 + az)^{-1-j/2} \quad j \approx 0$$

$$\frac{q_0}{\alpha_0} = \text{constant} \quad (5)$$

The coefficient of recombination α depends principally on the electron temperature T_e . At the moment of ionization the mean electron temperature is constant and it approaches only very slowly the gas temperature T . Consequently we can put $j \approx 0$, or at least $j > -1$, which is another condition for bifurcation.

The remainder of free electrons at sunrise already mentioned, which makes the bifurcation more pronounced, appears above a critical level (h_c) defined by a critical gas density n_c deduced from $dN/dt = \alpha N^2$ (where, since $T \approx \text{constant}$ we put $\alpha \sim n^{1/2}$), giving

$$N_{\text{night}} = \frac{N_s}{1 + N_s \alpha_0 \sqrt{(n/n_0)}} \quad (6)$$

where t is the time from sunset, N_s the sunset value and the zero suffix denotes values related to an arbitrarily chosen level h_0 . When the second term of the denominator equals unity, we have $n = n_c$. High above n_c the gas is so rare that N_n is nearly constant during the whole night, while, below n_c , N falls rapidly to zero (Fig. 1c, dotted curve). h_c represents the lower boundary of the night ionosphere.

A similar mechanism⁸ seems to govern also the planetary nebulae.

PACKING OF SPHERES

Packing of Equal Spheres

J. D. BERNAL¹ has directed attention to the importance of geometrical models to represent the structure of liquids. A random packing of equal spheres may provide a useful model for an ideally simple liquid. One of the basic parameters related to an array of spheres is the packing density, that is, the ratio of the volume of the spheres to the total volume they occupy. The present experimental work arose from a suggestion by H. S. M. Coxeter² that some random array of equal spheres might conceivably have a packing density higher than for regular close-packed spheres (that is, either hexagonal close-packing or face-centred-cubic packing) which is $\pi\sqrt{2} = 0.7405$.

Several measurements have been reported on the packing densities of equal spheres made with balls poured into cylindrical containers. O. K. Rice³ found a 15 per cent decrease in the density of random packing as compared with regular close-packing. Rice considered his result to be in agreement with a value obtained by Westman and Hugill⁴, who had found a 20 per cent decrease. Neither of these results was intended to be precise, and it is likely that disturbing peripheral effects were present in both cases.

To obtain packing densities for random packing of spheres from measurements on balls poured into rigid vessels there are two basic experimental problems: (1) to establish a method of getting random packing which is not significantly disturbed by the walls of the container, and (2) to correct the measured packing densities for the peripheral errors so as to determine the packing density characteristic of space, that is, of infinite volumes.

The present experiments were carried out with steel balls of nominal $\frac{1}{8}$ -in. diameter. Two separate batches of balls were used, the first totalling about 6,000 in number, the second about 20,000. The balls were uniform to better than 10^{-4} in. within a batch. As supplied by the manufacturer, they had a very thin protective oil coating which was not removed.

Method of packing. Early in the work it was observed that when balls are poured into a rigid container there is a range of random packings with different total volumes. For example, when the $\frac{1}{8}$ -in. balls were poured into a 100 c.c. graduated cylinder up to 54.5 c.c., shaking and tapping quickly reduced the volume to 53.0 c.c. Continued gentle shaking produced no further reduction in volume. More vigorous shaking increased the volume. On the other hand, when the vessel was tipped horizontally and then slowly rotated about its axis and gradually returned to the vertical position the volume of the balls increased to 58.2 c.c. For all the rigid containers used, a similar effect was observed, namely, there is a range of random packings lying between two well-defined limits. The limits are called here 'dense random packing' and 'loose random packing'. For the dense packing the balls in the vessel are gently shaken down for about 2 min. For the loose packing the balls fill the vessel essentially by rolling down a slope of random-packed balls. The difference in the packing densities for the two kinds of packing is about 6 per cent. The individual measurements at either of the two limits were consistent to within ± 0.2 per cent.

In both kinds of packings the balls are always rigid in the sense that a uniform pressure over the top will not alter the packing. Even small non-uniformities in the pressure will readily cause a re-arrangement which might be considered similar to the flow of liquids. It is unlikely that in these experiments the packing of the balls was significantly influenced by the frictional forces between adjacent balls either in the filling process or in the final configuration.

Small spherical containers. The first series of measurements were made with six glass flasks of roughly spherical shape ranging in diameter from ten to twenty times the diameter of the balls. The smallest flask could contain about 600 balls, the largest (about 130 c.c.) nearly 5,000 balls.

The packing densities were found by weighing the vessel when filled with balls to determine their number and hence their intrinsic volume, and then weighing the vessel when filled with water to the same level in order to find the total volume. A correction was made for the density of water depending on the ambient temperature.

For spherical containers the peripheral error of the measured packing density is presumably proportional to the ratio of surface to volume, or to the reciprocal of the radius of the vessel, or very nearly to $N^{-1/3}$, where N is the total number of balls. A plot of the packing density, ρ , against $N^{-1/3}$ will therefore be a straight line which, when extrapolated to $N^{-1/3} \rightarrow 0$, gives the packing density in space, that is, for an infinite volume, or with no peripheral error.

The validity of the above procedure for eliminating the peripheral error was confirmed by a plot of the packing density of close-packed spheres contained within a sphere. (The necessary data were obtained with the aid of a table kindly supplied by Prof. C. C. Gotlieb of the Computation Centre, University of Toronto, giving the number of integral solutions of $x^2 + y^2 + z^2 \leq k^2$ for integral values of k up to 142. The work on this table has now been extended and will be published elsewhere.) The packing density was plotted against $N^{-1/3}$, where N is the total number of spheres, for N up to about 48×10^4 . As was expected, the graph was a straight line extrapolating to 0.7405, the density of close-packed spheres in space. Deviations of the points from the line were surprisingly large, amounting to as much as 2 per cent for N even as high as 10,000. Though with random packing the deviations should be greatly reduced, this theoretical result suggested that considerable scatter might be expected in the measured densities quite apart from experimental error.

The measurements with the small spherical flasks are shown in Fig. 1. The extrapolated values for the limiting packing densities are 0.63(4) for dense random packing and 0.59(1) for loose random packing.

Larger spherical flasks. With the second batch of balls an attempt was made to extend the measurements to larger flasks, that is, up to 500 c.c. The results gave points which did not follow the lines of Fig. 1, but the densities were slightly higher than expected. An examination of the packing of the balls at the surface of the flasks revealed that regions of near close-packing were occurring with irregular boundaries, rather like certain patterns seen in rafts of equal bubbles. No doubt the regular packing

was associated with the smaller curvature of the larger flasks. It appears that to maintain random packing throughout a vessel it is necessary to avoid even approximately flat surfaces.

A series of glass flasks up to about 500 c.c. in volume were made with dimples over their surfaces. Measurements of the packing densities were taken as in the case of the smaller flasks and the extrapolated values of ρ were found to be 0.63(5) for dense random packing and about 0.61 for loose random packing. Though these results are in reasonable agreement with the previous values, it was felt that in the larger flasks the control of the packing, particularly the loose packing, was not satisfactory.

Non-rigid containers: balloons. Three ordinary unextended balloons of different sizes (the largest 350 c.c.) were filled with balls and the density of packing determined. The volume of the balls was found from their weight, as before, and the total volume by immersion of the balloon in water in a graduated cylinder. The filled balloons could be gently 'kneaded' to produce dense random packing. There did not appear to be a simple way of studying loose random packing in a balloon. The packing density from an extrapolation of the three measured values gave 0.63, in agreement with the previous results. As would be expected, the peripheral error with the balloons was smaller than with the rigid containers.

Dimpled copper cylinders. The last set of measurements were made with a series of four copper cylinders, of diameters about 3.1, 3.9, 4.9 and 6.3 cm., and heights about three times the diameter. The largest with a volume of 500 c.c. would take up to 20,000 balls. The cylindrical shape was selected to provide easier control of the packing. The walls and bottom of the cylinders were impressed to a depth of 2 mm. with dimples about 6 mm. in radius and 15 mm. apart. Though the dimples were roughly in a rectangular array they were sufficiently irregular in size and spacing to prevent any significant regular effects on the random packing of the $\frac{1}{2}$ -in. balls.

Measurements of both loose and dense random packings were made at eight or ten heights for each of the four cylinders. In a given cylinder the packing densities were plotted against $1/h$, where h is the height of the volume used in the cylinder. The graph should be a straight line, and the value at $1/h \rightarrow 0$ should correspond to the packing in a cylinder of the same diameter but of infinite length. The plot for the 6.3 cm. cylinder is shown in Fig. 2. The extrapolated values of ρ for each of the cylinders were then plotted against $1/D$, where D is the diameter of the cylinder (Fig. 3). The graph should again be a straight line

Fig. 1. Packing density for steel balls in glass flasks. Packing density (ρ) versus $N^{-1/2}$. N is the number to fill the flask

Fig. 2. Packing density of balls in a dimpled copper cylinder No. 4 (6.3 cm. diam.). Packing density (ρ) versus $1/h$. h , Depth to which balls fill cylinder

Fig. 3. Packing density in cylinder of 'infinite' length obtained from extrapolations as in Fig. 2, plotted against reciprocal of diameter. Packing density $\rho_h \rightarrow \rho$ versus $1/D$. D is diameter of cylinder

and the value of ρ , at $1/D \rightarrow 0$, will be the packing density in space. The disadvantage of having to make the double extrapolation seemed to be outweighed by the advantages in the control of the packing. Individual measurements were reproduced to within 0.2 per cent. As seen in Fig. 3, the final values for the dense and loose random packings are 0.63(7) and 0.60(1) respectively. It is considered that these results are more reliable than the corresponding values obtained with the small flasks, relative to which they are somewhat higher.

When spherical balls are poured into rigid containers there appears to be a range of random packing densities possible, with the upper limit at 0.63(7) and the lower limit at 0.60(1). It seems unlikely that there are other stable random packing arrangements for equal spheres in space which have packing densities outside these limits.

Co-ordination of Randomly Packed Spheres

In following up earlier work on a geometrical model of liquid structure¹, we have been examining more closely the precise mutual co-ordination of spheres when arranged at random and more-or-less closely packed. As can be seen from Dr. Scott's communication, which came to hand during this investigation, there are at least two types of random packing: random close packing with an occupied volume of 0.64, and random loose packing with one of 0.60. The first of these packings we had already studied with wax balls contained inside a rubber balloon. Realizing, however, that the arrangement studied was liable to be distorted from that of random close packing owing to the compression, it seemed desirable to repeat the experiment with a larger number of approximately rigid spheres. Accordingly, these were now replaced with $\frac{1}{4}$ -in. ball bearings, about 1,000–5,000 in number in different experiments, well shaken down and compressed by winding round with thick rubber bands. This assembly appeared to be rigid, its occupied volume of 0.62 indicated a reasonable approximation to Scott's close-packed density, considering its limited size.

Table 1. ANALYSIS OF CLOSE AND NEAR CONTACTS

11	—	—	—	1	—	1	0
Number of balls						420	

* Centre of distribution. The cases marked in bold type contain between them more than half the balls.

The mass of balls prepared in this way while still compressed was soaked in black japan paint. After standing for some time the paint was drained off. The object here was to mark the nature of the contacts and distinguish between them. Surface tension drew the paint to the places where the balls touched (a), or nearly touched (b), the first giving rise to a black ring with a clear centre and the latter to a black spot (Fig. 4). Careful experiment showed that the near contacts were registered by this method up to a radius of 5 per cent greater than the diameter of the ball. After thoroughly drying the paint, the mass of balls was unwrapped, with an appearance resembling caviare (Fig. 5). When broken apart they showed many of the small clusters referred to as pseudo-nuclei², and a certain number of holes, none of which was observed large enough

Fig. 4. Diagram of method of marking (a) close and (b) near contacts between spheres. The areas of adherent black paint are marked

Fig. 5. Portion of random close packed ball assembly showing marks of further contacts

to contain another ball. About 400–500 of these balls, taken from the centre of the sphere to avoid the surface effects noted by Dr. Scott, were separately examined and a number of close and near contacts counted. They were sorted according to the numbers of both kinds of contacts, the results being shown in Table 1 (a). These give effectively the distribution of co-ordination types characteristic of random packing. The distribution, as can be seen, is extensive and skew; but the modes are clearly marked and do not differ much from the mean. A modal co-ordination lies between 8 and 9, the largest number having between 6 and 7 close contacts and between 1 and 2 near contacts. The means are 8.5 total, and 6.4 close contacts.

A later experiment using the slow rolling method of Dr. Scott on a mass of ball bearings supported on a highly irregular base gave the conditions for random loose packing with an occupied volume of 0.6. The results of the sorting here give lower co-ordinations all round. The modes were between 7 and 8 for the total co-ordination and between 5 and 6 for the close contacts; the means are 7.1 total and 5.5 close contacts. In the looser random packing it was evident that there were a number of large holes, and that the co-ordinations of particular balls were highly unsymmetrical; for many of them, all the contacts being on one side, the other side facing the hole.

The meaning of these preliminary observations seems fairly clear. In any random packing we would expect each sphere to be in close contact with at least four others, a necessary condition of stability, and at most twelve. This absolute upper limit is extremely improbable. The most probable average would seem to be six, as each sphere may be

Fig. 6. Histogram of contact numbers derived (a) from calculated random model and (b) from assembly of spheres

considered in general to rest on three others and in turn to support another three. The number of near contacts, however, is not determinate, except that the sum of the close and point contacts may not exceed twelve, and is very unlikely to approach that number.

By the process of shaking and pressing, the arrangements of the spheres are progressively altered so as to give the minimum volume, and hence the largest number of near contacts. The figure for the occupied volume of random close packing—0.64—must be mathematically determinable, although so far as we know undetermined. If it is one of minimum volume, then it is also one of minimum energy, corresponding to any monotonously diminishing form of centrally attractive forces. For, by definition, any variation of this structure, while not altering the number of point contacts, must necessarily increase the distances

between near contacts and thus diminish the energy.

The method used for marking near contact in the model would necessarily fail to note those between 1.05 and say, 1.25 of the minimum value, and these would to a measurable extent contribute to the total energy and should be included as physical neighbours in the sense of the first communication¹. We may consequently take the mean physical co-ordination of random close packing to be a little more than the value of 8.5 indicated. It probably lies between 10 and 11 (Fig. 6).

The difference between random close packing and regular crystalline close packing fits very well with the observations of rare gas liquids. The increase in volume when passing from regular to irregular is almost exactly the same—16 per cent observed in argon—while the static contribution to the internal energy should correspond to a latent heat of melting between one-quarter and one-sixth of the energy of evaporation as against the observed value of 1/5.5 observed in argon.

The mathematical status of physical random loose packing is not so evident, though it may represent the approximation of the liquid at higher temperatures. The change-over would correspond roughly, on the basis of volume, to a rise in temperature of 1/5 of the interval between the melting and critical points. This will also give a configurational change of internal energy of about 0.18 c./mol. as against 0.16 observed.

Further investigations are in hand to study the statistical contribution of the angles between the contacts between the spheres and also to examine even looser aggregates which can only be obtained in the model by the use of rough or sticky spheres.

This research was assisted by a grant from the Department of Scientific and Industrial Research.

FAILURE TO DEMONSTRATE INFECTIVITY OF NEWCASTLE DISEASE VIRUS NUCLEIC ACID PREPARATIONS

By PROF. A. A. BENEDICT, DONALD LEE and BARBARA WEST

Department of Bacteriology, University of Kansas, Lawrence, Kansas

FOLLOWING the isolation of the infectious ribonucleic acid (RNA) moiety from the tobacco mosaic virus (TMV)^{1,2}, infectious RNA fractions have been extracted from numerous animal viruses³⁻⁸. In contrast to the intact viruses, the infectivity of the extracts is ribonuclease (RNAase) sensitive, thermolabile, and is sedimented very slowly in the ultracentrifuge.

At the time that the present work was initiated no information on the infectivity of RNA preparations from the myxoviruses had been reported; however, recently Maassab⁹ and Portocala *et al.*¹⁰ described such fractions derived from influenza viruses. After repeated failures to detect infectious RNA from

chick embryo-adapted influenza viruses, we made additional attempts to obtain infectious RNA fractions from Newcastle disease virus (NDV). Employing the cold phenol technique¹, the NDV extracts so prepared lacked infectivity in chick embryos. The existence of numerous variables in this type of study has become increasingly obvious from the reported results of others. Thus, exhaustive attempts were made to extract an active NDV RNA fraction by varying the conditions which are summarized as follows:

Egg-adapted strains (Iowa 23 and Calif. 11914) were used in the form of crude infected allantoic fluid, partially purified concentrated allantoic fluid,

Table 1. FAILURE TO DEMONSTRATE INFECTIVITY OF NEWCASTLE DISEASE VIRUS NUCLEIC ACID PREPARATIONS

Abbreviations: CAM, chorioallantoic membranes; BME, Eagle's basal medium; CEF, chick embryo fibroblasts; AF, allantoic fluid; BSS, balanced salt solution.

and chorioallantoic membranes. Concentrated allantoic fluid pellets were re-suspended either in phosphate buffer (pH 7.0), 0.85 per cent saline, or in Hanks's solution minus calcium, magnesium and phosphate ions¹¹. Chorioallantoic membranes were either extracted immediately or stored at -70° C. The -log of the chick embryo LD₅₀ titres of the virus preparations to be extracted varied from 7.0 to 12.0.

Many experiments employed the cold phenol method for the extraction of crude and concentrated allantoic fluid virus, and for virus from chorioallantoic membrane released by prior homogenization. Also, chorioallantoic membrane was homogenized in the presence of phenol. In addition, the following reagents were used for extraction: hot phenol¹², hot 1 M sodium chloride¹³, 8 M urea¹⁴, and 2.5 M guanidine¹⁵.

In view of the reports that the ionic strength of the diluent alters the degree of infectivity of RNA preparations, the following diluting fluids were used: 1 M sodium chloride, 0.1 M phosphate (pH 7.0), 1 and 2 × conc. mixture 199, 2 × conc. Eagle's basal medium, 0.9 M potassium chloride + 0.03 M tris buffer¹¹, and 1 × conc. Hanks's balanced salt solution. Most of the preparations were tested undiluted, and diluted 10⁻¹ with the above diluents.

Various reports suggest that the nature of the host and the route of infection might influence the RNA infectivity; that is, inactivation of infectivity presumably might be due to host RNAase in the cells or fluids. To obviate this possibility, the present work employed chick embryo allantoic and amniotic routes, chick embryo fibroblast monolayers in bottles, and chick embryo fibroblast culture tubes with cover-slips. Infectivity of the RNA extracts was ascertained by testing for viral hæmagglutinin in the chick embryo and tissue culture fluids, and by observing tissue cultures for cytopathic effects. In certain instances fluids were repeatedly passaged in chick embryos and no infectivity was detected.

The results of some of the experiments are summarized in Table 1, and a few are noteworthy of further attention. Exp. 1 (Table 1) was performed to determine whether there was a relationship between infectivity of the RNA and the period during the virus growth-cycle, since Maassab⁹ reported that infectious RNA was obtained from influenza-virus chorioallantoic membranes only at the peak of virus

production (18 hr.). Ten-day-old embryos were inoculated with 10⁻³ dilution of NDV, and 18 membranes were removed for each time-interval given in Table 1. For each time period membranes were stored for LD₅₀ determinations and 12 membranes were extracted by the cold phenol method. Cell culture tubes were inoculated with undiluted extracts and 10⁻¹ dilution of extracts in 2 × conc. Eagle's basal medium. A 60-min. adsorption period was used. After 7 days the experiment was terminated and cytopathic effects (May-Grunwald staining of cover-slips) and hæmagglutinin determinations failed to show virus activity, although the chorioallantoic membranes harvested after 24- and 36-hr. incubation had LD₅₀ titres above 12.0.

In view of the repeated failures reported in Table 1, infected chorioallantoic membranes were extracted with 8 M urea according to the method of Frazer *et al.*¹⁴. The urea extracts failed to show infectivity in either chick embryos or in chick embryo fibroblast monolayers. Similarly, virus released from chorioallantoic membranes was extracted with 2.5 M guanidine and 0.005 M versene¹⁵. An alcohol-precipitable material of the guanidine extract was not infectious for chick embryos.

In additional experiments concentrated NDV allantoic fluid suspensions and infected chorioallantoic fluid were extracted by heating to 95-100° C. in a water-bath in the presence of 1 M sodium chloride for 35 sec., according to the method of Kaper and Steere¹². The resulting extracts, untreated and treated with RNAase, produced cytopathic effects and hæmagglutinin in chick embryo fibroblast culture tubes, and plaques in monolayers. Apparently the intact virus particles were able to survive the extraction procedure. The period of heating in 1 M sodium chloride was extended to 1, 3, and 5 min., and the extracts obtained from a concentrated allantoic fluid virus (LD₅₀ = 11.0) and from chorioallantoic membranes (LD₅₀ = 12.0) were non-infectious. Although infectivity was not detected in any of the sodium chloride extracts, ultra-violet absorption and chemical analyses revealed the presence of nucleic acid.

Considering the relative complexity of the myxoviruses, attempts were made to 'reconstitute' the virus by mixing cold phenol extracts with either a protein fraction of the virus or with the *Vibrio*

cholerae receptor-destroying enzyme. The protein fraction was obtained by extraction with 67 per cent acetic acid¹⁶ and was added to phenol extracts. In another attempt, 5,120 units of receptor-destroying enzyme were added to various dilutions of phenol extracts. None of these preparations produced detectable infectious units in the chick embryo. It was noteworthy that the reagents and techniques used in this work were efficacious in producing infectious RNA from poliovirus.

No direct proof was found that RNA is the unit which initiates the formation of new infectious virus material or haemagglutinin from NDV preparations in the systems studied. The failure to isolate an RNA fraction from the myxoviruses which is infectious for chick embryos is not unique. Such observations have been confirmed by others¹⁷⁻¹⁹, who during the course of our investigations were unable to establish infectivity of myxovirus RNA preparations in embryonated eggs. Definitive evidence to explain this failure had not been given, although the presence of RNAase in the embryonic milieu had been suspected. This implication might not be valid, since RNA fractions of Western equine encephalomyelitis virus¹² and Type I poliovirus²⁰ infect embryonated eggs. Similar to our findings, Schäfer was not able to obtain an infectious RNA from fowl plague virus after phenol treatment¹⁹. Also, Schäfer kindly reported to us that he was unable to demonstrate infectious RNA fractions from either NDV or from influenza virus employing the extraction procedures which were used in the present work. We attest to Schäfer's views¹⁹ that possibly the RNA of NDV is relatively unstable, or that, in contrast to TMV and to other animal viruses, 2 units of RNA are needed for the formation of new infectious particles; one for the production of the *g*-antigen, and the other for the production of haemagglutinin. Indeed, myxoviruses might be considered to be more complex than the other viral agents which have been studied.

In view of Maassab's⁹ findings, we had fully expected to demonstrate infectious NDV RNA in cell monolayers. Perhaps the most obvious explanation would be lack of sufficient viable particles in the material used for extraction; however, this is unlikely. The NDV suspensions had titres of approximately 10^9 TCID₅₀/ml. and some with chick embryo LD₅₀ titres greater than 10^{10} .

Pertinent to this study is the report by Portocala²¹ that only freshly isolated filamentous forms of

influenza virus yielded infectious RNA, and that no active RNA was obtained from chick embryo-adapted virus. The significance of this finding remains to be determined in consideration of the reported successful isolation of infectious RNA from chick embryo-adapted influenza virus⁹. In this connexion, Portocala¹⁰ treated influenza virus with ether before phenol extraction, a procedure which is known to disrupt the nucleoprotein.

Finally, the NDV RNA might produce only non-infectious units or *S*-antigen (*g*-antigen), and no haemagglutinin and infectious virus. Although we have no evidence, Schäfer informed us that he was unable to demonstrate this possibility.

Grateful acknowledgment is made to Dr. George Dubes, University of Kansas Medical Center, Kansas City, Kansas, for supplying Type I poliovirus and for assaying poliovirus RNA extracts for infectivity, and to Mr. Franklin Newman, Kansas State University, Manhattan, for kindly supplying the NDV strains, and for advice on plaque formation techniques.

This investigation was supported in part by a research grant, F-2046, from the National Institutes of Health, U.S. Public Health Service.

BINDING OF HÆMATIN BY HUMAN SERUM ALBUMIN

By PROF. H. N. LITTLE

Department of Chemistry, University of Massachusetts, Amherst, Massachusetts

AND

PROF. J. B. NE'LANDS

Department of Biochemistry, University of California, Berkeley, California

METHÆMALBUMIN was identified by Fairley¹ as a complex of serum albumin and ferriprotoporphyrin. Although a number of workers²⁻⁴ have studied certain of its properties, little information is available concerning the nature of the protein-

hæmatin linkage. Keilin⁵ postulated for the reduced complex that the linkage is with the porphyrin and not with the iron. O'Hagan⁶, who observed that human serum albumin combined with proto- and meso-hæmatin but not with ætiohæmatin, concluded

that the propionic acid groups of the porphyrin were involved in the formation of the complex. The present article presents evidence concerning the protein groups involved in the binding of human serum albumin with haematin.

We have investigated the binding behaviour of a number of chemically modified derivatives of human serum albumin. A commercial preparation of human serum albumin (Cutter Laboratories) was used, and the following values for the albumin were taken in making the calculations: molecular weight 69,000 (ref. 5); (E) 1 per cent/cm. at 280 $m\mu$ = 5.3 (ref. 5); histidine residues per molecules, 16 (ref. 6). A change in the binding behaviour of human serum albumin was observed qualitatively as a change from the normal absorption spectrum of methemalbumin which, as reported by Rosenfeld and Surgenor³, had absorption maxima at 623, 540 and 500 $m\mu$. Quantitative measurement of such a change was accomplished by determination of the optical density of the Soret band (400 $m\mu$). Experiments with this human serum albumin showed that absorption at this wave-length was proportional to the protein concentration when the ratio of the molar concentration of the protein to haematin was between 0.2 and 1:2.

Our work has indicated that modification of the free amino-groups of human serum albumin does not appreciably alter the ability of the protein to form a complex with haematin. Three different samples of human serum albumin which had been acetylated roughly 50 per cent⁷ (determined by the ninhydrin method⁷) showed a decrease of only 0.22 per cent in their optical density at 400 $m\mu$ when compared with a solution of native human serum albumin of identical protein and haematin concentration. Similarly, two different preparations of guanidinated human serum albumin⁸ showed, when assayed in the same fashion, no decrease in the intensity of the Soret band. These two latter preparations had 54 and 44 per cent of their free lysine groups guanidinated as determined by their yield of ϵ -dinitrophenyl lysine after hydrolysis of the guanidinated protein which had been treated with fluorodinitrobenzene⁹.

We have, however, obtained some evidence which indicates that the histidyl groups of the protein are important for the binding of iron porphyrin. Since Gurd and Goodman¹⁰ have shown that zinc ions can become bound to the imidazole residues in human serum albumin, experiments were carried out to determine the effect of zinc on the complexing of human serum albumin with haematin. For these experiments, unbuffered protein solutions containing haematin, 0.15 M potassium nitrate, and zinc chloride were used. All solutions were adjusted to pH 6.0. Spectra of such solutions showed that zinc ions, when added at a final concentration of 0.005 M , prior to the haematin solution, completely prevented development of the characteristic visible absorption spectrum and caused a decrease and broadening in the Soret band of methemalbumin.

Experiments using fluorodinitrobenzene also have implicated histidine in the binding of haematin with human serum albumin. Although fluorodinitrobenzene is known to react with amino, sulphydryl, phenolic and imidazole groups, these acetylation studies and the following observations make it appear that it is the imidazole group the modification of which is significant in the work with fluorodinitrobenzene reported here. Preliminary experiments indicated that the visible spectrum of haematin plus human serum albumin which had been exposed to the follow-

ing reagents failed to show any major change from that of normal methemalbumin: (a) 0.02 M iodoacetate (at pH 8.5, 5.5, and 3.0); (b) *p*-mercuriphenylsulphonate¹¹ (two-fold amount of molar concentration of the protein); (c) iodine¹² (34-fold amount of molar concentration of the protein).

Human serum albumin which has reacted with limited amounts of fluorodinitrobenzene does not form, in the presence of haematin, the typical absorption peak at 620 $m\mu$ of methemalbumin. Although the dinitrophenyl-protein derivative itself has appreciable absorption at 400 $m\mu$, a decreased absorption in the Soret region can also be demonstrated as a result of the reaction of the protein with fluorodinitrobenzene.

Fig. 1. Relative optical density at 400 $m\mu$ for the complex between haematin and acetylated human serum albumin which has reacted with varying amounts of fluorodinitrobenzene. Absorption is expressed as per cent of that observed for the control complex of acetylated human serum albumin and haematin.

Fig. 1 indicates such a decrease resulting from the reaction of acetylated human serum albumin with varying amounts of fluorodinitrobenzene. For this work an amount of 0.04 M fluorodinitrobenzene (in 95 per cent ethanol) equivalent to a 14-fold amount of the molar concentration of protein was added to 2.9×10^{-5} M acetylated human serum albumin (57 per cent acetylated) in 0.3 M bicarbonate buffer, pH 9.3. This solution was incubated at room temperature, and at the end of the appropriate time intervals aliquots were removed for analysis. The moles of fluorodinitrobenzene which had reacted were calculated from the difference in its concentration at the beginning and at the end of the reaction¹³. For spectrophotometric measurements, a 1-ml. aliquot was added to 5 ml. of 0.2 M phosphate buffer, pH 7.4, containing 5.8×10^{-5} mM haematin and a second was added to phosphate buffer only. The absorption at 400 $m\mu$ of the latter solution was considered as the absorption of the dinitrophenyl derivative of the protein and was subtracted from the absorption at the same wave-length of the first solution. This corrected reading was then expressed as a percentage of that of a control solution prepared from the protein which had not been treated with fluorodinitrobenzene. Fig. 1 shows that only a few moles of fluorodinitrobenzene per mole of protein was required to react with the acetylated human serum albumin before a noticeable decrease occurred in the Soret band of the protein-haematin complex. What

protein groups reacted with fluorodinitrobenzene in this experiment have not been established. However, since many of the free amino-groups were protected by acetylation and since their modification does not appreciably affect complex formation in any event (see above), it is possible that the effects resulting from the reaction with fluorodinitrobenzene were a consequence of a modification of the histidyl moiety of the protein.

Further evidence for the involvement of histidyl groups in the protein-haem linkage comes from work on complex formation between haematin and human serum albumin which has been photo-oxidized. Weil and co-workers¹⁴⁻¹⁷ have demonstrated that for a number of crystalline proteins, photo-oxidation in the presence of methylene blue resulted in a rapid decrease in the histidine and tryptophan content of the protein and a more gradual decrease in the tyrosine, methionine, and cystine content on prolonged oxidation. We have found a similar rapid decrease in the histidine and tryptophan content and a much slower decrease in the tyrosine content of human serum albumin photo-oxidized under the same conditions. Histidine was estimated colorimetrically after acid hydrolysis and separation by paper chromatography¹⁸, and the tyrosine and tryptophan were determined by the methods of Bernhart¹⁹ and Shaw and McFarlane²⁰ respectively.

Fig. 2. Relative optical density at 400 mμ for the complex between haematin and human serum albumin photo-oxidized to varying degrees. Curve A observed with human serum albumin oxidized in the presence of haematin, and curve B observed with human serum albumin oxidized in the absence of haematin. Absorption is expressed as per cent of that observed for the control complex of native human serum albumin and haematin

The photo-oxidation of 1 per cent human serum albumin in phosphate buffer, pH 7.4, was carried out in a Warburg respirometer at 30° according to Weil's procedure²¹. Three different incubation conditions were employed: (a) incubation in the light with a two-fold molar amount of haematin; (b) incubation in the light with no haematin; (c) incubation in the dark. Condition (c) resulted in no oxygen uptake, and was used as a control for the spectrophotometric studies and for the histidine determinations. The number of moles of histidine oxidized was proportional to the number of moles of oxygen uptake and for a given number of moles of oxygen consumed the disappearance of histidine was identical for both conditions (a) and (b). At the completion of the photo-oxidation all the flasks were

placed in the dark, haematin was added to the flasks incubated under conditions (b) and (c), the methylene blue was removed by 'Norite' (activated charcoal), and aliquots appropriate for spectrophotometric or amino-acid analysis were removed from the filtrate.

Fig. 2 indicated that the absorption in the Soret region for the complex between haematin and human serum albumin which had been photo-oxidized fell regularly with a decrease in the histidine content of the protein. It is also evident that human serum albumin when photo-oxidized in the presence of haematin showed a greater degree of complex formation than did a sample which had the same histidine content but which had been photo-oxidized in the absence of haematin. This observation could be explained by the supposition that haematin, when complexed with human serum albumin, protected certain histidine groups of the protein which were essential for complex formation. The possibility remains, however, that the effects observed are a consequence of the involvement of more profound changes in the structure of the molecule than just a loss of histidine content. Brake and Wold²² have reported that photo-oxidation of enolase resulted in some heterogeneity of the enzyme as observed in the ultra-centrifuge.

Although none of the evidence presented above is conclusive by itself, when the results from the work with zinc, fluorodinitrobenzene, and photo-oxidation are considered together, we believe that they represent fairly strong evidence for considering that histidyl groups are involved in the binding of haematin with human serum albumin.

NUCLEAR STRUCTURE OF HUMAN SPERMATOZOA

THE recent communications by Shettles^{1,2}, claiming that discrete chromosomes could be demonstrated in dried unstained smears of human spermatozoa and that X- and Y-bearing types could be morphologically distinguished, and the comments by Rothschild³ and Bishop⁴ induce me to join the discussion. Rothschild, not accepting Shettles's claims, asks for an explanation of what, in reality, has been observed. In my opinion there cannot be the slightest doubt that Shettles has misinterpreted a number of optical artefacts. Special reference should be made to the work of Oettlé, who investigated the effects of varying conditions in phase-contrast systems, including exact measurements of phase-retardation in dried unfixed human spermatozoa⁵, and the occurrence of optical artefacts⁶.

Objects that are not completely flat, exert a focusing action like tiny lenses⁷. In the case of spherical particles, an image can be produced of another object at some distance without much distortion, whereas in the case of structures of cylindrical or irregular curve-bounded shapes, any image produced will be highly distorted. If the diffraction images produced by a number of structural details exerting lens-like action overlap, highly intricate interference patterns can be produced that do not bear any morphological relationship to either the structure producing the image or to the more distant object⁸. In phase-contrast, structures with focusing action can produce images of the phase-diaphragm below the condenser. With a population of structural details at different planes along the optical axis, the plane of optimal focus for one part of the structure may coincide with that in which other out-of-focus details produce a spurious image⁹. If heavy aberrations are introduced into the optical system, such as spherical aberration and coma, produced by neglecting tube-length correction with high-power dry objectives and by faulty alignment of the optical components, blurring of the total image occurs which may render the spurious effects more difficult to recognize.

All these effects are present in the photomicrographs published by Shettles. Since I have investigated thousands of human spermatozoa with a large number of different techniques⁹⁻¹², including several types of phase-contrast (both with annular and cross-shaped phase stops) and interference microscopy, I am not at all unfamiliar with the way in which such artefacts may be produced. The round heads of Fig. 1 of Shettles's first communication most clearly show a spurious image of the annular phase-stop, whereas the longer ones show heavy optical membranes around an unsharp central image, probably of a head in side or semi-side view, closely conforming to the types of optical artefacts analysed by Oettlé⁶. His Fig. 2 also shows very heavy optical membranes, a clearly recognizable image of the phase annulus in the round sperm head, and an overall blurring due to spherical aberration and coma, the optical system being out of alignment as proved by the one-sided dark shades. Shettles's Fig. 3 shows the same

phenomenon in reversed contrast; in the round sperm head the spurious image is even a perfect circle, which should have made every observer suspicious, since generally cell structure does not conform so perfectly to a geometrical shape, whereas in the longer head, optical distortion of this image has occurred owing to the rather different shape of the specimen.

Neither do the photomicrographs supplied in the second communication support his case. Fig. 1 has been produced with the optical system admittedly out of alignment "to show third dimension" (*sic*). This photograph shows very heavy haloes around the heads and one-sided interference fringes along the tails, whereas the shadows inside, erroneously interpreted as 'chromosomes', result only from the eccentric illumination; if the condenser system is brought in alignment, such shadows are shifted to the centre of the cell. The final clue is given by Shettles's second Fig. 2, which far from proving his claims, definitely settles the account, so far as physical optics are concerned. The 'chromosomes' most certainly result from an interference pattern produced by out-of-focus details both in the specimens and outside.

In the background of the picture to the left a number of interference patterns is shown, in which the shape of the phase annulus can still be recognized. The superposition of such patterns, further modified by light scattering and diffraction, may easily explain the production of the final image, which is completely out of focus with respect to the specimen itself! The same holds true for the long head, where there are at least as many 'chromosomes' to be seen outside the sperm head and surrounding it as inside, the only difference being that the outside interference pattern shows less contrast and is situated in a different focal plane, as is only to be expected, the specimen modifying the wave-front by lens-like action. The optical section in this specimen being approximately spindle-shaped, lens-like action along the longitudinal axis is much less than across the stronger curved transverse axis, thus explaining why the interference pattern here shows a mainly longitudinal array, while in the round head a circular pattern prevails. If instead of an annular phase-contrast system a cross system, as manufactured by Messrs. Baker, is used, similar interference patterns are obtained if the microscope tube is lowered after optimal focusing, however, with the difference that instead of a circular basic pattern, a rectangular pattern is produced; if, on the other hand, the tube is raised above the position of optimal focus, a bright image of the cross diaphragm of the substage appears, thereby proving the artefactual nature of the phenomena.

Finally, it should be emphasized that with the kind of phase-contrast employed (Zeiss positive PH), if the specimen appears dark against a lighter surround, any chromosome should appear dark, too, and not bright, as in Shettles's second Fig. 2, since phase-retardation of chromosomes is always higher

Fig. 1. Living human spermatozoon, photographed with Zeiss phase-contrast system while swimming, showing well-defined nucleus. Normal specimen; no evidence of spurious effects ($\times 1,000$)

Fig. 2. Dried, unfixed and unstained human spermatozoon, dry mount. Photographed with ordinary transmitted illumination with dry objective N.A. 0.65 ($\times 1,000$). Normal specimen, showing well-defined nucleus and extension of midpiece into the head. No evidence of spurious effects

Fig. 3. Heads of human spermatozoa showing positive Feulgen reaction (dark) after treatment with concentrated acetic acid. Resin mount, photographed with Zeiss annular phase-contrast oil-immersion system. The round head to the right clearly shows a similar optical artefact to those depicted by Shettles and interpreted by him as an X-chromosome. The artefact nature of the phenomenon is clearly demonstrated by the same image, with exactly the same dimensions, appearing outside the specimens in the background. The two heads near the bottom do not show distinct spurious effects ($\times 2,670$)

Fig. 4. Same slide as 3, showing similar artefact inside and several times outside the sperm head. If the centre of the artefact image should have shifted just past the border of the head, the head would have shown optical artefacts of similar shape as shown by Shettles in his photographs of 'male' sperm heads ($\times 2,670$)

Fig. 5. Feulgen reaction applied without pretreatment; ordinary transmitted illumination. Black area, positive test; grey, counterstain ($\times 2,000$)

Fig. 6. Human spermatozoon in dry mount without any further preparation, photographed with annular phase-contrast oil-immersion system, demonstrating that the optical artefacts can be as easily obtained with immersion objectives as with dry ones, but with much better definition, greatly facilitating recognition of artefacts. Spurious effects shown: images of phase diaphragm both inside and outside the sperm head, corresponding to the artefactual structures called X-chromosomes by Shettles; heavy optical membranes; interference fringes recognizable up to the third order. No detectable effects of spherical aberration or coma; optical system in good alignment as shown by symmetry of interference fringes ($\times 4,000$)

All photographs by the author

than that of other nuclear components and cytoplasm, whereas exact measurements with interference microscopes show that phase shift is not yet sufficient to produce contrast reversal with the phase plates used in the Zeiss PH system. I may add that with properly adjusted phase-contrast optics there is no difficulty at all in observing dried unstained spermatozoa with oil-immersion objectives; any structure that is really present must, if it can be observed with a dry objective, also be observable with oil-immersion.

Now the problem remains of the presence of two distinct populations of different shape and size. If

this should be the case, a bimodal size-frequency distribution must be expected, and also a bimodal distribution of nucleic acid. Thus far, bimodal size distributions have never been found, either in normal spermatozoa or in pathological specimens^{15,16}, and the same holds true with respect to nucleic acid, arginine and total dry mass¹⁴⁻¹⁶. To prove this part of his claims, Shettles should supply extensive biometrical data (size-frequency distributions and mathematical

proof of significance if any tendency to bimodal curves should occasionally be observed).

Giant sperms, with heads more than 8μ long, do exist; but these are definitely abnormal¹⁷. Shettles's magnification calibration remains at fault, his new photographs giving head-length values of the order of $30-50\mu$. It may be incidental, but both types of sperm heads have been observed previously in abundance in varying amounts in abnormal ejaculates^{18,19}; this makes it even more unlikely that these should bear any relationship to sex ratio.

Although the arguments of physical optics and of biometry must in themselves be considered as final, it is only fair to add some cytological data, since it is to this part of my own work that Prof. D. W. Bishop⁴ especially refers. Contrary to the condition in somatic interphase nuclei, chromosomal material in the sperm nucleus is not highly hydrated and therefore the possibility of optical differentiation cannot be excluded *a priori*. However, since no method of microscopical observation, not even the most sensitive methods of interference microscopy, has revealed any such structural detail in the living specimen, it is concluded that any chromosomal material must be highly compressed, a condition

Fig. 7. Size frequency distribution curve (ref. 12) of 1,500 human spermatozoa from donors of proved high fertility, measured with phase-contrast in the living state. L , length of head; N , absolute number. The curve follows the mathematical equation

$$N = N_{\max} \cdot \exp\left(-k\left(\ln \frac{L}{L_m}\right)^2\right)$$

and demonstrates complete absence of any bimodality. Modus, 4.4μ ; mean, 4.5μ

which again produces optical homogeneity. There is no reason why, in such a colloid-chemical system, simple drying should produce any effect other than shrinkage of the gel as a whole, so optical differentiation cannot be expected in this case either, contrary to experience with somatic cells. If simple drying should produce separation of discrete chromosomes, these should also be demonstrable by electron microscopy, which even with the most advanced techniques has not been the case^{20,21}.

Shettles² claims that the Feulgen test, being positive in the centre of the head, should support his views. In fact, this is not so. Apparently, to support the idea of distinct chromosomes being present, these structures should be demonstrated by the Feulgen reaction itself on observation with ordinary bright-field microscopy, phase-contrast pictures of dried and stained unmounted specimens obviously being equally liable to optical artefacts as unstained ones. Although differentiations that may point to demonstration of chromosomal structure have been obtained in the form of Feulgen-positive material remaining after an extractive treatment with concentrated acetic acid^{11,12}, consistent results obtained without rigorous chemical pretreatment, with the Feulgen reaction^{12,14-16}, Robinow staining¹² and staining (including vital) with methyl green¹², all confirm that in the native sperm nucleus the chromatin material is in a condensed karyosome form, contraverting Shettles's statements.

From a purely cytological point of view the final argument may be raised by asking why chromosomes in a 'female' spermatozoon should appear more or less globular and in the 'male' sperm elongated, while it is known that no such differentiation is found in autosomes and neither in the ovum, and why the individual forms, even in the same types of sperms, should not show reproducible shapes, which conflicts with all we know about chromosomes.

BRIGHT-LIGHT microscopy has been used for more than thirty years and phase-contrast microscopy for ten years, the latter in studies of more than two thousand human oocytes and ova. If these methods are not used properly by one who knows what he is observing, many errors can be made.

Thin, dried smears of normal spermatozoa from more than 200 men of proved fertility have now been studied. In each individual the two populations of spermatozoa already reported^{1,2} concerning nuclear morphology have been seen (Figs. 8 and 9). The

Fig. 9. Unstained, dried human spermatozoa. Phase contrast ($\times c. 430$). Light adjusted to show third dimension

Fig. 10. Chromosomal patterns in the rounded and elongate types of spermatozoan heads. Front views. The Feulgen-positive chromosomes are dumb-bell-shaped and touch end-on like pearls of a necklace. Phase contrast ($\times c. 860$)

chromosomal patterns in the two types of heads are shown in Fig. 10. The chromosomes are dumb-bell in outline and touch end-on like pearls of a necklace. In some spermatozoan heads sufficiently flattened, all 23 chromosomes have been seen. On breaking the thick membrane of the spermatozoan head, the Feulgen-positive, discrete, separate, dumb-bell-shaped chromosomes are easily and readily observed. In every man there has been the exact pattern of the Feulgen-positive, concentrically arranged chromosomes around the most central, rounded chromosome in the smaller, rounded type of head, and an ovoid pattern in the more elongate type (Fig. 10).

PHOTO-ASSIMILATION OF ACETATE BY GREEN ORGANISMS

By PROF. E. G. PRINGSHEIM and DR. W. WIESSNER

Pflanzenphysiologisches Institut, Göttingen

Acetate Flagellates

FORTY years ago the senior author¹ published a paper showing that for a colourless flagellate *Polytoma uvella* acetate is a specific nutrient. Up to this time it had only been known that these organisms live in a complex mixture of so-called putrefaction products. Although it seemed surprising at the time, this result attracted little attention then. Acetic acid is now known to play a prominent part in the metabolism of most organisms.

Polytoma deposits starch as a reserve which it is unable to produce from glucose, whereas acetate is readily transformed into starch.

Lwoff² showed that there are more colourless and also green flagellates, not all closely related to *Polytoma*, which produce body material and polysaccharides, and gain their energy from fatty acids in the dark much in the same way. These flagellates were therefore called acetate organisms³.

The impression that acetate as a nutrient is of considerable importance was strengthened by the observation that some chlorophyllous organisms were greatly assisted in multiplication by acetate in the light. *Euglena gracilis* and *Chlorogonium elongatum*, for example, are able to live by photosynthesis but grow poorly without acetate. Others, like some colonial Volvocales, though green, cannot grow at all without acetate, even under conditions favourable for photosynthesis⁴. The facility with which these live on acetate in the dark varies from organism to organism.

Chlamydomonas and its Nutrition

Organisms with a complex and variable nutrition did not prove suitable for elucidating the way acetate and light work together in the metabolism of green flagellates. By testing numerous forms⁴ we came across a genus of colonial Volvocales, *Chlamydomonas*⁵, which, though distinctly green, is quite unable to live by photosynthesis in the absence of acetate,

which, however, is not sufficient to cause it to grow in the dark.

Ten strains were isolated from material collected in widely separated localities. Some, which multiplied faster than the rest, proved suitable for experiments because of their multiplication at relatively high temperatures. All of them require acetate, the vitamins thiamin and cobalamin and an organic source of nitrogen in addition to inorganic salts, including trace elements. The medium ought to be neutral or slightly alkaline. Optimum temperature is 25–30° C. and light intensities 2,000–5,000 lux. Acetate cannot be replaced by other organic acids or by sugar or alcohol. For most experiments a mixture described in our laboratory as *Euglena gracilis*-solution was used. The composition is: sodium acetate 0.1 per cent, 'Difco' tryptone 0.2 per cent, 'Difco' yeast extract 0.2 per cent, beef extract 0.1 per cent.

The inability of *Chlamydomonas* to multiply unless both acetate and light were provided required an explanation. There were several possibilities: (1) Light may be required not as a source of energy but because some 'photomorphotic' influence is essential for growth. Green and blue light was not effective, but red was, and there are further reasons (ref. 5, Chap. 4) why this explanation is not satisfactory. (2) Normal photosynthesis might not be sufficient to support growth, a situation known in a few faintly pigmented flagellates. Supplementation by another source of energy, acetate in this case, would therefore be required. However, this explanation is again not satisfactory. First, *Chlamydomonas* is quite green, and secondly, the pale organisms, referred to above, grow in darkness. (3) It may be assumed that both an organic substrate and light energy are necessary because of a photochemical reaction in which acetic acid is involved and which takes place in the chromatophores⁶. If so, 'normal' photosynthesis would not be involved and consequently carbon dioxide would not be required nor would oxygen be produced.

This hypothesis was tested in various ways.

Culture Experiments

Independence of carbon dioxide for the growth of *Chlamydothrys* with acetate in the light was investigated:

(1) Cultures in test-tubes with cotton-wool plugs and containing acetate medium were kept under an air-tight bell jar. Carbon dioxide was removed by potassium hydroxide solution absorbed on filter paper covering a glass cylinder. This increased the effective absorbing surface exposed to the gas. Growth was the same as outside in air.

(2) Absorption of carbon dioxide might have been too slow because of the large volume of the jar. Cultures as above were therefore grown in small test-tubes individually enclosed in larger ones. Each rested on a short length of glass tubing so that the lower portion of the outer tube could be filled with potassium hydroxide up to the bottom of the culture tube. Growth was normal. *Chlorogonium elongatum*, two strains of *Euglena gracilis* and *Chlorella vulgaris* were also found to multiply under these conditions.

(3) A medium of *Euglena gracilis* solution as in (1) and (2) with 0.5 per cent agar was melted, boiled in test-tubes to remove dissolved gases, cooled to 42° C., inoculated, stirred by repeated pouring backwards and forwards in sterile tubes, and eventually solidified in cold water.

Green colonies developed throughout the 10-cm. high agar column. There was no difference in size between the colonies at the bottom and those near the surface. *Euglena gracilis* behaved in the same way, while several other green flagellates in contrast showed a denser growth near the surface than in the depth.

(4) A possible objection to the previous experiments is that some carbon dioxide might still have been left or produced by respiration. Cultures were therefore prepared through which air, freed from carbon dioxide by potassium hydroxide, was continually bubbled. One washing bottle with barium hydroxide was inserted in the gas line and one behind the cultures.

Growth took place as usual, and only a very slight production of carbon dioxide was detected. *Euglena* and *Chlorogonium* also multiplied.

A further objection might be that respiration could have occurred with the production of carbon dioxide which was immediately consumed in photosynthesis. Anaerobic growth with acetate in the light was therefore believed to be worth testing. *Chlamydothrys* grows in putrid conditions as well as in the depth of pure cultures⁶ and in an agar column.

(5) By excluding oxygen along with carbon dioxide the absence of normal photosynthesis could be established unambiguously. Cultures mounted as in (2) were therefore prepared with pyrogallol acid added to potassium hydroxide solution so that both carbon dioxide and oxygen were absorbed.

Growth was unimpaired compared with cultures in contact with the air (through the cotton-wool plug), and so was that of *Euglena* and *Chlorogonium*.

(6) Instead of air, nitrogen free of carbon dioxide and oxygen was bubbled through the cultures. As in all these tests the pressure inside the culture vessels was slightly greater than atmospheric. Complete absence of oxygen was established by using wash-bottles with pyrogallol in potassium hydroxide. As an indicator, and to make certain that no trace of oxygen was left, Wittingham's⁷ anthra-

quinone-2-sulphonic acid in alkaline solution was used in wash-bottles inserted in the gas stream before and after the culture tubes.

Growth was again normal.

(7) To ensure anaerobic conditions sodium sulphate was added to the medium. Two kinds of experiments were performed.

(a) To 23 ml. portions of nutrient solution with acetate 2, 4 and 6 drops of 1 per cent sodium sulphide solution were added. Each medium was distributed into test-tubes with screw tops and soft washers. In the light the *Chlamydothrys* strains, *Euglena*, *Chlorogonium* and *Chlorella* grew in the normal way. They are therefore not hampered by a hydrogen sulphide concentration in excess of that required to bind all free oxygen.

(b) Sodium sulphide solution was added to liquefied agar medium with acetate which had been inoculated with the same organisms at 41–42° C. and solidified. Green colonies developed down to the bottom without difference in size, except in the case of *Euglena* and *Chlorogonium*, which showed denser growth near the surface.

These tests established the fact that *Chlamydothrys* multiplies in the absence of carbon dioxide and oxygen when acetate and light are provided. Since growth is no slower in these conditions than in control tubes, initial carbon dioxide production by respiration with following photosynthesis is ruled out.

Our culture experiments, though instructive in respect to living conditions and nutritional requirements, were not deemed sufficient to elucidate the peculiar metabolic features which *Chlamydothrys* appears to have. Moreover, experiments with some other green organisms known to live heterotrophically on acetate had shown that *Euglena gracilis*, *Chlorogonium elongatum* and *Chlorella* (strain 211/11h Beijerinck) can live likewise, multiply anaerobically with acetate in the light, although they are also capable of normal photosynthesis.

The culture experiments were therefore supplemented with measurements of gas exchange and pH shifts with and without acetate and light respectively. Again five strains of *Chlamydothrys* and the three other algae were used.

Experiments on Metabolism

Two kinds of experiments on the metabolism of our organisms were undertaken: (1) Measurement of gas exchange with the Warburg technique; (2) the following of acetate consumption by measuring the rise of pH and titration with hydrochloric acid to constant pH.

In these experiments the temperature was 25° C. The living material was grown in 300-ml. tubes through which air with 5 per cent carbon dioxide was bubbled. Neutral *Euglena gracilis* solution was mixed with the same volume of a dilute inorganic nutrient solution with trace elements and ethylenediamine tetraacetic acid. The density and dry weight of the cultures was less in the case of *Chlamydothrys* than in *Euglena* and *Chlorogonium* but satisfactory. The living material was centrifuged off, washed twice in neutral M/100 phosphate buffer containing inorganic nutrients without nitrate and ammonium and for the measurements transferred into the same buffer solution. Acid and alkaline solutions were harmful and could not be used. The healthy state of the delicate living material was ascertained after the experiments.

Fig. 1 Anaerobic utilization of acetate by *Chlamydomobryx*. Light, 14,000 lux; temperature, 25° C. The uptake of acetic acid was measured as amount of 0.05 N hydrochloric acid needed to keep the pH constant

(1) In the five *Chlamydomobryx* strains oxygen consumption in the dark in a medium without energy substrate was low, on the average 2/3 that of *Chlorogonium*, a little higher than that of *Chlorella* and 1/2 that of *Euglena gracilis*. With acetate added, oxygen consumption of *Chlamydomobryx* was increased by 40 per cent and that of *Euglena* by 70–80 per cent, while that of *Chlorogonium* became four times and that of *Chlorella* ten times that without. Glucose had only negligible influence on the respiration of the three flagellates, which are also unable to utilize it for growth, while that of *Chlorella* increased six times.

Photosynthesis at 14,000 lux measured as oxygen production in air with 5 per cent carbon dioxide was also low in *Chlamydomobryx* (in three strains almost nil) while the other organisms gave quite a good response. With acetate added there was no production but a consumption of oxygen by *Chlamydomobryx*, though less than in the dark, no doubt owing to a feeble photosynthesis. In *Chlorogonium*, *Euglena* and *Chlorella* oxygen was produced by photosynthesis in the presence of acetate; but it was appreciably reduced by its addition.

These photosynthetic experiments were supported by measuring the production of oxygen with the dropping-mercury electrode⁸. The relative quantity of oxygen produced showed the same relation between the various strains.

(2) Acetate-consumption in the dark and in the light was estimated by Clayton's⁹ (1955) technique¹⁰. A specially devised glass vessel was provided with a magnetically activated stirrer. A glass electrode was immersed in the medium for measuring pH, and titration with hydrochloric acid was used to keep the pH constant. The experiments were done under anaerobic conditions (nitrogen atmosphere). The vessel was kept at a constant temperature of 25° in a water-bath, which also protected it from heat accompanying the strong external illumination.

We measured the influence of illumination and of addition of acetate on the hydrogen ion concentration. With acetate in the solution, turning on the lamp resulted in an immediate rise in pH, while in the dark it remained constant. With the light on, addition of acetate resulted in an instant increase of pH, while it remained constant (Fig. 1) in the dark.

The very rapid influence of the addition of acetate shows that it took almost no time for the molecules to penetrate through the cell wall and protoplasm into the chromatophores. It also renders improbable a long chain of intermediate metabolic processes to be passed before acetic acid is converted into a non-acid compound with the help of light energy. The quantity of acetic acid consumed was about the same in four of the strains of *Chlamydomobryx*, while in the fifth it was 50 per cent higher. In *Chlorogonium* it was about three times as much as the average of *Chlamydomobryx* while *Euglena* had the lowest consumption.

We conclude that the same process of anaerobic photo-assimilation of acetic acid as in *Chlamydomobryx* also takes place in *Euglena*, *Chlorogonium* and *Chlorella*, which in addition are endowed with normal photosynthesis which in *Chlamydomobryx* is negligible.

It is proposed to call the new reaction photo-assimilation of acetate as opposed to the photo-assimilation of carbon dioxide, which in itself is not a 'synthesis'. The investigations are being continued.

TRANSLOCATION FROM LEAVES OF RYE

By DR. A. MAYER and PROF. HELEN K. PORTER, F.R.S.

Agricultural Research Council Unit of Plant Physiology, Imperial College of Science and Technology, London, S.W.7

THE filling of the cereal grain is accomplished as a result of the assimilatory activity of the top leaf and sheath on each tiller, together with that of the ear itself¹. During this time, however, there may be up to five green leaves on a single tiller from which photosynthate could be translocated. Movement of material from such leaves has now been examined in the rye plant by supplying single leaves with carbon-14

dioxide and determining the distribution of radioactivity in materials soluble in ethanol and in water (mainly sucrose and fructose polymers) throughout a tiller after assimilation of the carbon-14 dioxide followed by a period in air and light.

Petkus winter rye was grown in the open in pots. Five plants were selected at the time of anthesis, when the stems were fully extended and the top

(flag) leaf was approaching full expansion. An amount of carbon-14 dioxide equivalent to 5.5 mgm. of hexose was supplied to one leaf of plants exposed to bright sunlight. The lowest leaf (1) was yellowing and was not included in the sequence of leaves (numbers 1-5, bottom to top) receiving carbon-14 dioxide. Assimilation of carbon-14 dioxide was complete in 2-2½ hr., and the plants were then left in air and light for a further 2 hr. In a further experiment, in which the third leaf from the bottom was exposed to carbon-14 dioxide, the plant was left under normal conditions for three weeks, by which time the ear had reached its maximum dry weight. The amount of radioactivity in the soluble material of each part of the tiller was estimated, and in the last experiment in both soluble and insoluble fractions. The results are summarized in Table 1.

Table 1. DISTRIBUTION OF RADIOACTIVITY IN THE SOLUBLE MATERIAL* OF TILLER PARTS OF RYE, FOLLOWING ASSIMILATION OF CARBON-14 DIOXIDE BY A SINGLE LEAF

Carbon-14 dioxide (total activity 360×10^3 c.p.m., amount = 5.5 mgm. hexose) was assimilated in 2-2½ hr. Plants then kept in light and air for a further 2 hr.

Leaf receiving carbon-14 dioxide numbered from tiller base	2	3	4	5	3
Leaf fresh weight (mean of 4 in mgm.)	269	362	275	106	250
Time after start of exposure to carbon-14 dioxide			4-4.5 hr.		3 weeks
	Percentage of total activity supplied in carbon-14 dioxide				
					Insoluble
Whole tiller (by addition)	83	76	46	50	2
Treated leaf	80	39	26	26	1
Sheath of treated leaf	3	17	1	5	1
Stem internodes	0	15	19	15	1
Ear	0	4	—	5	1

There was no activity in untreated leaves and only traces in some sheaths. Roots were slightly radioactive in all plants.

* Each part extracted successively with 80 and 50 per cent ethanol, and then three times with cold water. Extracts combined.

The range of distribution through the tiller, after 4 hr., of carbon-14 from a single leaf was limited. No activity appeared in leaves other than those receiving carbon-14 dioxide, and only traces in leaf sheaths. In stems, activity was mainly in two internodes, one above and one below the insertion of the sheath of the treated leaf.

The proportion of radioactive material in soluble form in the whole tiller and in the treated leaf depended on the position of the leaf on the tiller. There was little translocation from the oldest leaf treated (leaf 2), for, at the end of the 4-hr. period, 80 per cent of the carbon-14 assimilated was in the extract from this leaf. With leaf 3, 37 per cent of the carbon-14 was in the extracts from the leaf sheath and stem internodes, and 39 per cent remained in the leaf extract, so that 76 per cent was in soluble products. Only a small fraction of the activity reached the ear (4 per cent). With the two upper leaves (4 and 5), 50 per cent of the assimilate remained in the soluble form after 4 hr., of which about half was in the treated leaf, 17 per cent in the stem, and about 5 per cent in the ear. In the plant left for three weeks after treatment of leaf 3, only 7 per cent of the initial activity persisted anywhere in the tiller. More than half this amount was in the insoluble fractions of leaf 3 and the stem internodes, and less than a third (less than 2 per cent of the initial activity) in the ear. Qualitative observations showed a small amount of activity in adjacent tillers, and rather larger amounts in roots. These amounts, together with respiration losses, presumably accounted for the

disappearance from the tiller, over the period of grain filling, of about 90 per cent of the carbon-14 previously assimilated by leaf 3. These results certainly support the view that assimilation by lower leaves on cereal tillers does not contribute materially to the growth of the grain.

Paper chromatograms (propanol/ethylacetate/water) prepared from samples of the tissue extracts were sprayed with benzidine to show the distribution of saccharides and radioautographed to show the distribution of radioactivity. In all parts of the tiller there was present, in addition to sucrose, fructose and glucose, an array of fructose polymers which appeared on the paper as a sequence of spots above sucrose extending to the starting line (cf. ref. 2). In extracts of the leaves which had received carbon-14 dioxide, although most of the activity was in sucrose, all the fructose polymers were radioactive. In sheaths and the stem internodes, however, activity was confined to sucrose. It is remarkable that no trace of activity was found in the large array of soluble fructose polymers present in these tissues.

By combining all the ethanol/water extracts, an estimate of the proportion of the activity in sucrose and in the fructose polymers of the leaves was obtained after fractionation of the saccharides on a charcoal column. The radioactivity was distributed between six fractions eluted respectively by water, 5, 20, 30, 50 and 80 per cent ethanol. Water removed 13 per cent of the activity from the column, presumably in hexoses. 5 per cent ethanol removed 82 per cent, of which all but 1 per cent was sucrose; this small fraction, which was eluted after sucrose, yielded only fructose and glucose on hydrolysis, and its position on a paper chromatogram suggested that it was a trisaccharide.

There remained a further 5 per cent of the activity incorporated into oligosaccharides. Four-fifths of this amount was eluted by 20 per cent ethanol. This material was resolved into three fractions by paper chromatography, the two faster-running substances being radioactive and probably tri- or tetra-saccharides. These substances also yielded only fructose and glucose on hydrolysis. Material eluted by higher concentrations of ethanol contained only traces of activity and did not move from the starting line on paper chromatograms. At the time of grain filling, therefore, synthesis of fructosans from newly assimilated carbon was virtually confined to formation of tri- and perhaps tetra-saccharides in the leaves, for at least 4 hr. following photosynthesis.

If sucrose is assumed to be the precursor of the fructose polymers, these results suggest that the transfer mechanism in leaves only slowly builds up the well-known series of fructose polymers. Furthermore, fructose polymers do not move out of the leaf with sucrose, and consequently accumulation in sheaths and stems must result from new synthesis from incoming sucrose. The amounts formed are known to depend in part on the nutritional status of the plant—and especially the nitrogen supply³. Since no labelling appeared in fructosans of the stems and sheaths in 4 hr., little new synthesis can occur after the time of anthesis, when in fact the overall amounts are falling (see ref. 4).

LETTERS TO THE EDITORS

COSMOLOGY

Interpretation of Cosmology

RECENT correspondence by McCrea^{1,2} and Davidson³ has been concerned with distinguishing between steady-state and evolutionary type cosmologies. In particular, McCrea¹ has suggested that there is a fundamental inability to distinguish experimentally between the two types, and that this fact should be built into any satisfactory cosmological theory. It is shown here by considering a gravitational formulation of Mach's Principle that it is possible to incorporate this indistinguishability directly into cosmology.

Gravitational formulations of Mach's Principle^{4,5} assume that the dynamical properties of a body are due to the gravitational interaction of the body with the matter composing the rest of the universe. The resulting gravitational potential of the body becomes a function of its velocity, so that the existence of kinetic energy and other dynamical characteristics are readily explained. Discussions of the advantages of such treatments have been published by Sciama⁴, Bastin⁵ and Burniston Brown⁶ and are too long to be given here in detail. It is noted, however, that, as well as accounting for the dynamical properties of bodies, the treatments give quantitative explanations of the existence of rest mass energy, the equivalence of gravitational and inertial mass, and the non-rotation of the 'fixed-star' directions with respect to inertial frames.

The properties of a universe of variable radius R but of constant mass M will now be examined. The gravitational form of Mach's Principle will be assumed, but, apart from this, physical mechanisms will be assumed independent of R . Thus the fundamental quantities (e , h , c and G) will be assumed to remain unaltered by a variation in R . In order for the variation of R to have a meaning, we must further suppose the existence of an invariant scale measuring distance and an invariant clock measuring time.

If R_0 is the present value of R , then expressions for the kinetic energy E and momentum p of a particle in a universe of radius R (see, for example, Bastin, ref. 5, sections 3 and 4) are:

$$E = \frac{1}{s} \cdot \frac{1}{2} mv^2 \quad (1)$$

and

$$p = \frac{1}{s} \cdot mv \quad (2)$$

where $s = R/R_0$ and will be called the dilation parameter. Equations (1) and (2) may also be inferred from the treatment given by Sciama⁴ in which (section 4 (iii)) it is shown that the contribution of distant matter to the inertia of a body falls off inversely as the distance of the distant matter.

Some implications of equations (1) and (2) are at once clear. For highly condensed cosmological conditions (low s), the energy and momentum of a particle (of given mass and velocity) are high. For

low-density conditions (high s), the values of energy and momentum are correspondingly less. This is in fact what would be expected qualitatively if the energy and momentum of a particle are considered to be the result of gravitational interaction of the particle with the rest of the universe.

Consider now a hydrogen atom in a universe of dilation parameter s (that is, radius $R = sR_0$). Using the normal Bohr treatment:

$$\frac{e^2}{r^2} = \frac{1}{s} \cdot \frac{mv^2}{r} \quad (3)$$

where r is the radius of the electron orbit. Quantization of action gives:

$$\frac{1}{s} \cdot mv \cdot r = \frac{n\hbar}{2\pi} \quad (4)$$

So that from (3) and (4):

$$r = \frac{sn^2\hbar^2}{4\pi^2me^2} \quad (5)$$

The corresponding expression for the energy change during an atomic transition becomes, from equations (2)–(5):

$$E = h\nu = \frac{2\pi^2me^4}{\hbar^2} \left(\frac{1}{n_1^2} - \frac{1}{n_2^2} \right) \cdot \frac{1}{s} \quad (6)$$

Equation (5) shows that the radius of the hydrogen atom bears a constant ratio to the radius of the universe R . The same would be expected for more complex atomic systems, so that any measuring rod would also vary in length in the same way. Since the invariant scale which was postulated is experimentally unrealizable, an observer will only be able to measure the ratio R/r which will be constant for all time. Thus whatever the radius R measured by the hypothetical (but unrealizable) invariant scale, the observer will always measure R_0 . It is thus impossible at any time in the past or future to measure any value for the radius of the universe other than the present one of $\sim 3 \times 10^{27}$ cm.

The analysis also shows that no indication of variation of R may be obtained from time-dependent measurements. Thus from equation (6) the period of atomic clocks is proportional to the dilation parameter s (and a similar result may be simply shown for a macroscopic mechanical clock). The linear dimensions of an atom, a measuring rod or the universe will also be proportional to s , so that the time measured by the observer's clock for light to traverse any of these objects will be independent of s and hence independent of the radius R .

When certain types of experiment are considered, the application of orthodox physics does not give the indistinguishability suggested by McCrea. Suppose, for example, a measurement of Hubble's constant is made at some particular time. Suppose further that this result is stored for a time which is an appreciable fraction of the parametric cosmical time ($\sim 10^9 - 10^{10}$ years) when a second measure of the Hubble 'constant' is made. According to orthodox physics, we should expect the two values of the 'constant' to be the same if a steady-state model is correct, whereas a

definite difference of the 'constant' would imply an evolutionary type cosmology. The experiment could thus distinguish between the two types of model. If, however, the idea of gravitational inertia is accepted, then the two values of the Hubble constant are necessarily the same, as has been shown above.

ASTROPHYSICS

Magnetic Field of Jupiter

RECENT radio observations of Jupiter, in the frequency-range 14–27 Mc./s., have suggested the presence of an ionosphere and a magnetic field on the planet. If the magnetic field is regarded as being due to a dipole situated at the centre of the planet, with its axis along the axis of rotation, a value for the polar field intensity of 7 ± 1 gauss can be found from the radio observations.

Radiation appears to be emitted from one or more localized regions on Jupiter¹. The radiation from these sources is emitted within a limiting angle, and this has been interpreted² as indicating the presence of an ionosphere in the upper atmosphere of Jupiter. Observations by Franklin and Burke³, Smith and Carr⁴ and Gardner and Shain⁵ have shown that a number of the noise bursts appear to be right-handed elliptically polarized when viewed along the direction of propagation. This polarization has been observed from both the northern and the southern hemispheres of the Earth. It is evidently not an effect of the terrestrial ionosphere, although further observations are necessary to establish this conclusively. Franklin and Burke³ and Barrow⁶ have explained the observed polarization as being due to internal reflexion, in the upper atmosphere of Jupiter, of one of the two components formed when the radiation passes through the Jovian ionosphere in the presence of a magnetic field.

The propagation of electromagnetic radiation in an ionized gas in the presence of a magnetic field has been fully discussed in the magneto-ionic theory of Appleton⁷. Most reflexion takes place at points where the refractive index tends to zero. In the presence of a magnetic field H the conditions for zero refractive index (if possible, collision effects are neglected) may be written as:

$$\frac{4\pi Ne^2}{m} = p_0^2 = (2\pi f_0)^2 \quad (1)$$

$$f_0^2 = f_x^2 - f_x f_H \quad (2)$$

$$f_0^2 = f_x^2 + f_x f_H \quad (3)$$

where N is the electron density, e and m are, respectively, the charge and the mass of an electron, f_0 and f_x are, respectively, the critical frequencies for the ordinary and the extraordinary waves, and f_H is the gyrofrequency ($f_H = He/2\pi mc$). The condition (1)

is independent of the magnetic field and refers to the ordinary wave. Conditions (2) and (3) apply to the extraordinary wave and they depend on the magnitude of the magnetic field although they are independent of the direction. Two cases arise as $f_H < f$ or $f_H > f$.

Consider a source of radiation at some point on Jupiter. Both mixed and polarized bursts have been observed on a number of occasions at 22.2 Mc./s. and we may, therefore, conclude that 22 Mc./s. is the approximate value of either f_0 or f_x .

If $f_H < 22$ Mc./s. reflexion of the extraordinary wave must occur at the lowest level of electron density, specified by (2). Signals have been received down to 14 Mc./s. so we can say that $f_0 < 14$ Mc./s. and $f_x \approx 22$ Mc./s. The maximum electron density is evidently not great enough to give rise to reflexion conditions (1) and (3) for 22 Mc./s. waves. Fourth condition reflexion of the extraordinary wave, if it occurs, will be a subsidiary effect as it would take place, for all inclinations of H to the direction of propagation, at electron densities between limits specified by (1) and (2).

A little consideration will show that it is not possible to explain the observed polarization at all if $f_H > 22$ Mc./s.

It seems probable, then, that when we observe an elliptically polarized burst on the Earth it is essentially the ordinary wave which is being received. If this radiation is observed to be emitted within a limiting angle λ , from a point having latitude φ on Jupiter, then it can be shown⁸ that:

$$\cos \frac{\lambda}{2} = \frac{f_0}{f} \sec \varphi \quad (4)$$

Franklin and Burke³ give $\lambda = 60^\circ$, for their 22 Mc./s. observations of the principal region emitting the radiation, whence $\varphi > 43^\circ$ if $f_0 < 14$ Mc./s.

To find the value of the polar magnetic field H_p , we note that:

$$H_p = \frac{2H}{\sqrt{1 + 3 \sin^2 \varphi}} \quad (5)$$

Combining (2), (4) and (5), we find that:

$$H_p = \frac{f_x [1 - (\cos \lambda/2 \cdot \cos \varphi)^2]}{1.4 \sqrt{1 + 3 \sin^2 \varphi}} \quad (6)$$

taking $f_H = 2.8H$ if f_H is in Mc./s.

H_p varies relatively slowly with the lower values of f_0 and it can be seen that for $0 < f_0 < 14$ we have, using $f_x = 22$ Mc./s. and $\lambda = 60^\circ$:

$$6.0 < H_p < 7.85 \text{ and } 90 > \varphi > 43$$

An average value of $H_p = 7 \pm 1$ gauss is indicated. This implies a critical frequency of about 10 Mc./s. for the ordinary wave and an approximate source latitude of 57° .

The above value of H_p is somewhat lower than that which follows from the estimate, given by Smith and Carr⁴, of about 7 gauss for the magnetic field intensity in the ionosphere at the point of propagation. This figure is obtained from their average, experimentally observed, polarization ratio, assuming f_0 to be 17 Mc./s. and the source latitude to be 20° . The field intensity is then calculated from the Appleton-Hartree polarization formula. The corresponding value of H_p is about 12 gauss.

On the face of the experimental evidence, any method of calculation is going to lead to the general

conclusion that f_H is something between 13 and 22 Mc./s. However, the method outlined here avoids any specific assumption as to the latitude of the source and might well form the basis of a more accurate determination of H_p in the future.

Field⁸ has proposed a cyclotron-like model of the radiation sources on Jupiter on the basis of decimetre wave-length emission. This model requires a polar field intensity of at least 1,200 gauss, and it is difficult to reconcile these two contrasting orders of magnitude for the polar field.

The radio observations of Gardner and Shain⁵ and of Franklin and Burke³ have cast some doubt on the hypothesis that the restricted angle of radio emission from Jupiter is due to ionospheric effects on the planet. However, in considering these results, it must be remembered that, as the method of interpretation is statistical, the fact that 27 Mc./s. radiation has been received so infrequently, compared to radiation in the 18–22 Mc./s. range, is liable to give misleading conclusions if the limiting angle is taken from a histogram compiled in terms of 'number of occurrences'. There is the further possibility that the spectral distribution is such that 27 Mc./s. signals only rarely reach an intensity which is detectable on the Earth. This could be the case if the radio emission is due to plasma oscillations. Zheleznyakov⁹ has shown that the main features of the radiation can be explained in terms of a plasma oscillation mechanism, and Rishbeth¹⁰ has shown that sufficient ionization for such a mechanism could be produced by solar radiation. Certainly the ionospheric hypothesis cannot be rejected on the experimental data available at present.

Future observations of polarization at two or three different frequencies may support or disprove the ionospheric theory. It is hoped to make these observations at this University in 1961.

PHYSICS

Direct Measurements of Proton Mobilities in Protonated Ice

PROTON mobilities in ice have been calculated previously only on the basis of indirect experimental evidence. Eigen and DeMayer^{1,2} have estimated from discharge experiments that in ice of pure water proton mobility is in the range 0.1–0.5 cm.² sec.⁻¹ V.⁻¹. Conway and Bockris³ calculated from conductivities of ice of pure water that proton mobility is 0.19 cm.² sec.⁻¹ V.⁻¹. Some theoretical estimations⁴ yield proton mobilities in ice of 0.11 cm.² sec.⁻¹ V.⁻¹. These mobilities are all extremely high when compared with

Fig. 1. A sketch for proton boundary movement (hydroxyl ion boundary movement is not considered here). Dye (D) used, malachite green; D', yellow (frozen) for 0.1 M hydrochloric acid; D'', blue after proton depletion; AB, initial boundary; A'B', migrating proton boundary; AB – A'B' region is blue; I, boundary positions initially; II, boundary positions after electrolysis

the mobilities of protons in liquid water (3×10^{-8} cm.² sec.⁻¹ V.⁻¹).

Protonated ice is a relatively good electrical conductor (Heinmets, F., unpublished results) which suggests that direct measurements of proton movement by the boundary method could be made. Prerequisites for such measurements are the establishment of a sharp moving proton boundary in ice and a proton concentration indicator-molecule to follow the boundary movement. After extensive exploratory work, the conditions for obtaining a suitable boundary have been established and an indicator-dye (malachite green) has been found which exhibits colour change in ice at a suitable proton concentration. I have made such direct measurements of proton mobilities in protonated ice.

Ice was obtained by freezing supercooled 0.1 M hydrochloric acid solutions. A U-type conductivity cell (length 30 cm.) was used in which one vertical section was plastic (diameter 1.2 cm. and wall-thickness 0.03 cm.). This facilitated sawing up the tube for sectional analysis. A stable proton boundary, suitable for mobility measurements, is obtained when a boundary is established between hydroxylated and protonated ice (Fig. 1). Half the plastic cell was first filled with 0.1 M hydrochloric acid solution (containing indicator dye) and was frozen. Afterwards a layer of 0.1 M sodium hydroxide solution, containing also a dye for better boundary indication, was poured on top of the ice and frozen. Some experiments were carried out in the presence of gelatin, since a visually sharper boundary is maintained during the electrolysis. The procedure here was as follows. Half the plastic section was first filled with 0.1 M hydrochloric acid solution, containing a proton indicator and 2 per cent gelatin, which gelled and was afterwards frozen. A layer of 0.1 M sodium hydroxide solution containing 2 per cent gelatin and metacresol purple was poured on top of this and frozen. This in turn was topped with a non-freezing electrolyte containing a 1 M sodium hydroxide solution in 50 per cent glycerol. For the other U-arm a 1 M hydrochloric acid solution, also with glycerol, was used. A d.c. potential was applied by means of platinum electrodes. To avoid warming the ice, current values were kept low. The initial boundary of yellow 0.1 M hydrochloric acid and purple sodium hydroxide was clear. Shortly after the application of a potential a blue boundary appeared between the purple-yellow interphase, and the blue zone gradually widened. The positions of the boundaries were determined at various time-intervals by switching the current off while the cell

was lifted from the bath and the boundary position measured rapidly. During electrolysis at constant voltage, the current value diminished because the blue-zone represents a proton-depleted ice region and its resistance increases with time. In my experiment the current was kept constant by increasing the potential. However, the increase of resistance is not too rapid, since all protons do not migrate out of the region immediately. Apparently all hydrochloric acid molecules are not dissociated in ice and protons migrate only after dissociation. In gel-ice it takes several hours before the resistance in the proton-depleted zone gets very high; during that time the boundary has moved several cm. After completion of boundary measurements, the cell was put into powdered dry ice. Using a duplicate cell, the electric field strength in the hydrochloric acid region was determined for selected current value. Then various sections of plastic cell were sawn off, melted and conductivity and pH determined. A thin section between sodium hydroxide-hydrochloric acid inter-phase was discarded. In Table 1 the result of a typical experiment is presented. Zone A-1 represents the proton-depleted region. During 180 min. at 1 m.amp. the displacement of the boundary was 1.1 cm. In the blue A-1 zone the pH value was 1.1 before and 3.3 after electrolysis. This was reflected also in resistance increasing from 4,000 ohms to

26,100 ohms. Both measurements reveal a large reduction of proton concentration in A-1 zone. In two control sections (A-2, A-3) at the front of the boundary there was no significant change in either the pH or the resistance value, nor was there a change in colour. Additional control experiments with hydrochloric acid solutions and malachite green revealed that the change in colour corresponds to the reduction of the proton concentration. This proton-depleted zone is shown in Fig. 2, which is a black-and-white copy of a colour photograph. All available evidence indicates that the blue zone in ice represents a proton-depleted region, and proton mobility is calculated from the length of the zone. Results are presented in Table 2. Since the conductivity of protonated ice decreases when temperature is lowered, it is expected that proton mobility is also reduced. The results in Table 2 confirm this phenomenon.

Table 1. RESISTANCE, pH AND COLOUR OF VARIOUS SECTIONS BEFORE AND AFTER ELECTROLYSIS

Length of section (cm).	Resistance (ohms)		+ B ↑ OH ⁻ NaOH HCl ↓ H ⁺	pH		Colour of ice	
	Before	After		Before	After	Before	After
	—	—		—	—	P	P
1.1	4,000	26,100	1	1.1	3.3	Y	B
1.5	4,000	3,850	2	1.1	1.1	Y	Y
1.5	4,000	3,750	3	1.1	1.1	Y	Y

Current of 1 m.amp. applied for 180 min. Temperature was kept at -15° . Electric field strength, 0.5 V./cm. A, 0.1 M hydrochloric acid, 2 per cent gelatin and malachite green; B, 0.1 M sodium hydroxide, 2 per cent gelatin and metacresol purple. P, Purple; Y, yellow; B, blue.

Table 2. VELOCITY OF PROTONS AS A FUNCTION OF TEMPERATURE

Experiment No.	Composition of ice	Temperature ($^{\circ}$ C.)	Velocity (cm. ²)
			sec.-volt.
1	0.1 M HCl + H ₂ O	-30	2.0×10^{-5}
2	0.1 M HCl + H ₂ O	-25	8.1×10^{-5}
3	0.1 M HCl + H ₂ O + 2 per cent gelatin	-22	2.4×10^{-5}
4	0.1 M HCl + H ₂ O + 2 per cent gelatin	-15	2.2×10^{-4}

In these experiments potential applied at the electrodes varied in the range 200–800 V. The velocity of proton was calculated as follows:

$$V^- = \frac{d}{e \times t}; \text{ in example at } -15^{\circ} V^- = \frac{1.1}{0.5 \times 180 \times 60}$$

where d , boundary displacement (cm.); e , electric field strength (V./cm.); t , time (sec.).

Temperatures reported here are those of bath; ice temperatures are slightly higher due to the passage of current. Electric field intensity for each experiment was determined by d.c. conductivity measurements in a duplicate cell. Same current values were used for conductivity measurements and for electrolysis.

Fig. 2. Proton boundary in ice. PR, Purple zone, 0.1 M sodium hydroxide plus metacresol purple; GR, blue zone, part of 'Y' zone whence protons have been removed by electrolysis; depletion of protons changes colour of ice from yellow to blue; Y, light yellow zone, 0.1 M hydrochloric acid plus malachite green (ice is yellow); A—B, initial proton boundary position; A'B', final boundary position

This black-and-white print has been prepared from a colour slide

It can be questioned how much diffusion contributes to movement of the proton boundary in the ice. A rough estimate of this has been made on the basis of measurements with a control cell which was stored at -28° C. for six months. Approximate velocity of diffusion boundary was 1×10^{-7} cm./sec. It appears that diffusion displacement of proton boundary is insignificant in experiments lasting only for a few hours.

It is evident that proton mobility in protonated ice is about three orders of a magnitude smaller than previously estimated^{1,3}. This raises the question whether previous indirect estimations and calculations are based on uncertain assumptions or whether, in the ice of pure water, a different mechanism is operating for the proton transfer process. Further work is required to elucidate this point. Unfortunately, moving-boundary methods cannot be used at very low proton concentrations. My experiments were carried out under conditions where current and temperature were regulated manually, and experimental error may be considerable, but the accuracy is

definitely better than an order of magnitude. Experiments are in preparation with automatic current and temperature control in order to obtain more accurate proton mobility determinations.

Electrostatic Attraction between a Liquid Surface and a Needle Height-Gauge

WHERE the height of a liquid surface needs to be measured accurately, it is customary to use a needle height-gauge. In a typical gauge a needle point is slowly lowered by a micrometer screw until the point just touches the liquid surface. The instant of contact is detected either visually or electrically, and the micrometer reading at that instant gives the height of the liquid surface. Such gauges are regarded as accurate to within ± 0.001 in. It has been found, however, that with a non-conducting liquid that has become electrically charged, errors of 0.025 in. can easily occur.

A laboratory needle gauge was being lowered towards a surface of mineral oil in a 'Perspex' vessel, when it was observed that, when the needle was held at a height of about 0.05 in. above the oil surface, a rhythmic disturbance of the surface occurred immediately below the needle. The frequency of this disturbance was usually of the order of 1 c./sec.

Subsequent investigation revealed that the 'Perspex' vessel had become electrostatically charged when it was being cleaned immediately before being filled with oil, and that this was the cause of the disturbance. When an earth wire was brought into contact with the oil at the site of the disturbance, the disturbance ceased at once, only to start again (but with diminished vigour) when the wire was withdrawn.

When the oil was replaced by de-ionized water, which has a much lower resistivity than the oil, the phenomenon did not occur. After the oil had been allowed to stand exposed to the atmosphere for a few days, only very slight disturbances could be produced. This was due to the absorption of atmospheric moisture by the oil and the consequent decrease in resistivity; the oil was afterwards dried by prolonged agitation in a vacuum desiccator, and immediately it became possible to produce the disturbances again on the same scale as when the oil had been fresh.

Evidently the cycle of events is as follows: (1) When the oil is put into the charged container the charge slowly spreads across the surface of the oil. (2) When the needle is brought close to the oil, the charged oil immediately below is attracted towards it, thus producing a hump in the surface, in which the combined effects of gravity and surface tension are balanced by the electrostatic attraction. (3) The needle, being earthed, acts like a lightning conductor and the hump is rapidly discharged. (4) The hump collapses suddenly. (5) The electrostatic charge on the surrounding area spreads slowly over the discharged area, and the cycle begins again.

Fig. 1

Once started, this cycle of attraction and collapse is likely to continue for hours before the charge is completely dissipated.

When the needle is lowered closer to the surface of the liquid, a point must obviously be reached when the hump in the surface comes into contact with the needle. Contact once having been made, it is maintained permanently by surface tension. In the experiments described above, contact usually occurred when the needle was between 0.020 and 0.025 in. above the level of the surface.

There is thus a serious risk of erroneous readings when a needle gauge of the normal design is used to measure the level of a non-conducting liquid. This risk may be eliminated very easily by adding an earthing wire to the needle, as shown in Fig. 1.

Finely Ground Quartz: Evidence against a 'Disturbed' Layer

BRISCOE *et al.*¹ discovered that the rate of solution of a finely ground quartz powder decreases slowly from an initially high value to a much smaller steady value. Kitto and Patterson² concluded that the effect could not be accounted for on the basis of particle size alone and attributed it to edge effects and the presence of a 'Beilby layer', presumably of amorphous silica. Further evidence of an amorphous layer has been reported by various authors using X-ray diffraction^{3,4}, electron diffraction⁵, differential thermal analysis^{6,7}, rate of solution^{8,9}, and density^{8,9}.

measurements. Some, not wishing to commit themselves as to its exact nature, have called it a 'disturbed' layer. Estimates by a variety of methods^{3,5-9} put the thickness of the layer at between 300 Å. and 1,500 Å.

Doubt was cast on the existence of an amorphous or non-quartz layer by the electron diffraction observations of Finch, Lewis and Webb¹⁰ and of Heavens¹¹, and by the discovery that a similar decline in the rate of solution occurs in the case of vitreous silica⁹.

Taking into account all the experimental results, King and Nagelschmidt¹² adopted a model of the quartz particle composed of a central core considered to be highly crystalline quartz, surrounded by a transitional layer about 300-600-Å. thick in which the highly crystalline structure of the core is supposed to change gradually to an effectively amorphous state near the surface. The surface itself is supposed to consist of a monolayer of silicic acid.

We were led to doubt the validity of this model by the ease with which electron diffraction patterns are obtained from finely ground quartz. The following observations were made as a test of the model.

(1) The electron diffraction patterns of numerous untreated ground quartz particles of diameter 1-5 μ were compared with those of similar particles after leaching in 20 per cent hydrofluoric acid for 5 min. Collodion films, on which the electron beam was incident normally, were used to support the particles. The diffraction patterns of the untreated particles differed from those of the treated quartz in having a higher background, more intense haloes, and in many cases weak spotty rings. In other respects they were similar. The strong individual spectra were commonly observed to show marked asterism (Fig. 1 (inset)). Examination of a large number of patterns revealed no tendency for the asterism to be more pronounced normal to the radii joining the spectra to the zero order spectrum than in other directions. It was concluded that the effect was due to refraction of the electrons on entering and leaving the particles, and not to lattice strains or other crystal imperfections which would have caused arcing of the spectra normal to the radii.

Fig. 1. Dark-field image of a quartz particle formed by one diffraction maximum (inset). The asterism of the diffraction maximum is due to refraction of the electrons

Fig. 2. Dark-field image of a particle treated with hydrofluoric acid, after shadowing with silica

(2) Dark-field images of the diffracting particles were formed in an electron microscope by using an eccentric objective lens aperture so as to accept only one diffraction maximum. The images show that the diffraction patterns are produced by transmission through thin edges of the particles (Fig. 1). Images of the untreated and of the treated quartz were found to be equally distinct. Shadowing the untreated quartz with silica at 45°, producing a layer of silica about 150 Å. thick in a direction normal to the plane of the supporting film, resulted in marked diminution of the clarity of the images, these becoming blurred in one direction (Fig. 2). This is believed to be due to inelastic scattering of the diffracted electrons in the silica layer. The effect was observed in nearly all cases where the particles had been coated with silica, but in no case was it observed with untreated quartz particles.

(3) Kikuchi *N* and *L* patterns from thin layers of quartz near the surface of the particles were observed. This was achieved by making carbon surface replicas of the particles using an etching time of 10 min. which resulted in some of the particles being incompletely removed from the replicas. Many remnants thin enough for the observation of *N* or *L* patterns were found. No differences of any significance were found between the patterns of the untreated quartz and those of the treated quartz. Twenty patterns of each were observed, and in no case were any rings or any arcing of the spectra observed.

In the light of the above observations the King-Nagelschmidt transitional layer or a 300-Å. layer of purely amorphous silica seems unlikely. A gradual transition from a crystalline core to an amorphous surface layer would presumably imply a reduction in the sizes of the crystallites and an increase in the disorder of their orientation with increasing distance from the core. A layer of this type would be expected to cause the following:

- (a) pronounced arcing of the spectra, or rings of varying intensity along their length;
- (b) an increase in the intensity of the background and of the haloes; and
- (c) a marked diminution of the clarity of the dark-field images of the diffracting edges.

Effects (a) and (c) have not been observed. Rings have been observed in the diffraction patterns described in (1), but the intensity is roughly uniform along their length and not greater in the vicinity of the strong spectra, which would be the case if the above model were correct. We consider it more likely that the rings are produced by the numerous small particles which have been observed to cling to the surfaces of the larger particles¹³. Effect (b) has been noted in the observations (1) but could equally well be due to the numerous adhering particles which are thin enough to transmit electrons but are not orientated for Bragg reflexion.

We are of the opinion that the numerous small particles which are always found adhering to the larger particles of ground quartz, and which are extremely difficult to disperse, offer a plausible explanation of all the effects usually ascribed to an amorphous or 'disturbed' layer. This will be discussed in a more detailed account of this work to be published elsewhere.

We wish to thank Mr. P. H. Kitto for many valuable discussions and the Transvaal and Orange Free State Chamber of Mines for permission to publish this communication.

Electrical Resistivity of Nickel Ferrite

UP to the present the only systematic investigation published on the semiconducting behaviour of ferrites is a study of cobalt ferrite, CoFe_2O_4 , by Jonker¹. In the case of other ferrites insufficient information of the basic structure of the material has impeded an understanding of the electrical properties. In the case of nickel ferrite it is known that these properties are closely related to a small deficiency, δ , of oxygen (a few tenths of 1 per cent) which occurs when the ferrite is formed in the sintering process. This may be represented by $\text{NiO} + \text{Fe}_2\text{O}_3 \rightarrow \text{Ni}^{2+}\text{Fe}_{2-2\delta}^{+++}\text{Fe}_{2\delta}^{++}\text{O}_{4-\delta} + \frac{1}{2}\delta(\text{O}_2)$. The creation of iron ions with two valencies in the crystal lattice is known to lead to a marked lowering of activation energy of conduction electrons², and the resistivity of nickel ferrites therefore depends on the temperature and atmosphere of the sintering process and on the rate of subsequent cooling. To produce high-resistivity nickel ferrite it has been found desirable to sinter at relatively low temperatures (below 1,300° C.) in an

Fig. 1. Activation energy against $\log_{10}$ oxygen pressure for stoichiometric nickel ferrite. ●, 1,100° C.; ×, 1,150° C.; ○, 1,200° C. firing temperature

oxygen atmosphere^{3,4}; but it is very doubtful if a nickel ferrite with electrical properties representative of the stoichiometric material has so far been produced.

In order to investigate the influence of oxygen pressure during sintering on the electrical properties, a closed system was constructed which allowed specimens to be sintered in a quartz tube under various oxygen pressures. It was found that a pressure of up to about 6 atmospheres could be maintained at temperatures of 1,250° C.

A stoichiometric mixture of spectroscopically pure nickel monoxide and ferric sesquioxide was ball-milled for 24 hr., pre-fired at 800° C., milled again and then pressed into specimens which were fired under various oxygen pressures at 1,100° C., 1,150° C. and 1,200° C., respectively. Specimens were then slowly cooled (2 deg. C./min.). Firing times in each case were sufficiently long for the reaction to have been completed. This was judged from measurements of both magnetic moment and from the fact that a further period of firing did not alter the electrical resistivity. After surface grinding, resistivity measurements were made at d.c. and at frequencies of up to several Mc./s. and no significant dispersion was observed. The temperature dependence of resistivity could be expressed by the usual semiconductor equation⁵ $\rho = A \exp \epsilon/KT$. A was found to be in the range of 0.1–1 ohm cm. in each case and values of ϵ are plotted in Fig. 1 against the logarithm of oxygen pressure. Measurements of thermo-electric power showed that all specimens had negative Seebeck coefficients of about 2 to 3×10^{-4} V./deg. C. indicating n -type conductivity.

Specimens were also prepared from a mixture containing a nickel oxide excess which may be represented by $\text{NiO} + (\text{Fe}_2\text{O}_3)_{0.95}$. The corresponding relationships of activation energy and sintering pressure are shown in Fig. 2. Thermo-electric measurements showed that in every case the conductivity is n -type on the low-pressure side of the peaks (Fig. 2) and p -type on the high-pressure side. Measurements of saturation moment were carried out with an accuracy of 1 per cent and showed that no detectable amount of nickel excess had entered the ferrite crystal lattice, this being in complete agreement

Fig. 2. Similar to Fig. 1 for nickel excess ferrite + 1,250° C. firing temperature

with the results of Derry *et al.*⁴. The magnetic measurements do not, of course, preclude a concentration of excess nickel ions in the ferrite lattice of less than 1 per cent, and indeed the most plausible interpretation of the results is that a small concentration of the excess nickel oxide has indeed been dissolved in the ferrite lattice giving rise to Ni^{+++} ions. Under high sintering pressure the ferrite loses an insufficient amount of oxygen to reduce all the excess nickel ions to a valency of two; the dominant conduction mechanism is now by nickel positive holes¹. At sufficiently low sintering pressures more oxygen is lost than that needed to remove all trivalent nickel ions and some of the electrons released by the oxygen create divalent iron ions; specimens of this type are therefore *n*-type conductors. The peak in activation energy corresponds to a change of *p*- to *n*-type conduction and represents the condition where the number of oxygen atoms lost during sintering is equal to half the number of excess nickel atoms dissolved in the ferrite. As in the case of Jonker's results for cobalt ferrites, it is likely that the theoretical peak value in activation energy is somewhat greater than that shown in Fig. 2 on account of imperfect compensation and submicroscopic inhomogeneities in the specimens.

The results presented here lead to the following conclusions. In the process of nickel ferrite formation some loss of oxygen occurs even at 1,100° C., which is only slightly inhibited by the application of pressures up to 6 atmospheres. By introducing excess nickel into the ferrite lattice and by suitable adjustment of sintering pressure an approximately compensated nickel ferrite can be prepared in which the intrinsic activation process comes into effect. The systematic shift of the peak in activation energy to the higher-pressure region indicates that the loss of oxygen increases with sintering temperature.

We wish to express our gratitude to Prof. E. R. Andrew and Dr. D. Wooller for their encouragement in this investigation.

VOLCANOLOGY

Drilling into Molten Lava in the Kilauea Iki Volcanic Crater, Hawaii

THE November 1959 eruption at Kilauea Iki, Hawaii, produced a lava lake more than 300 ft. deep containing about 45 million cubic yards of lava. An experiment was conducted to obtain knowledge of the problems encountered when drilling through the crust of the lake into molten rock, and to obtain as much volcanological data as possible.

On July 25, 1960, after drilling 19 ft., the crust of the lava lake was pierced, making possible temperature measurements of the molten rock, collection of gas samples emanating from the melt, and direct sampling of molten lava.

The experiment clearly demonstrated that it is possible to drill into hard rock at temperatures up to 850° C. with standard core-drilling equipment, using compressed air to cool the rock and to remove the cuttings. By using water to cool the rock and drilling with water periodically injected into the compressed air line, it is possible to drill with standard equipment into rock that has been at temperatures exceeding 1,050° C.

The first 14 ft. of the hole was drilled to 3.5 in. in diameter and cased to seal off possible communication with the surface. Vibration as a result of air drilling limited core recovery and diamond bits were badly damaged by heat and inadequate air circulation; otherwise, drilling proceeded rapidly. The remainder of the hole was left uncased and drilled to a 2-in. diameter. Drilling progressed more slowly due to the high temperatures encountered and also an increase in the rock density. At 15.5 ft. silver solder on the bits melted and core recovery was poor. Binding of threads on the drilling tools caused considerable difficulty; however, powdered graphite as a lubricant cured this trouble. At 16.8 ft. water was used to cool the hole and was periodically injected into the compressed-air line for additional cooling during drilling. This worked very well, and the drilling increased from 1.5 ft. in 8 hr. to 3.5 ft. in 3.5 hr. Core recovery remained poor, but there was little damage to the drill bit.

The crust-melt boundary was encountered at about 19 ft., and the melt was quite fluid at 20 ft. The air-and-water-vapour drilling coolant quenched a protective crust between the bit and the melt and further drilling did not cut this crust, but pushed it into the melt. At 19.5 ft. the bit and tools dropped

slowly in the hole of their own weight. A core of melt was then taken by cutting off circulation, allowing the silver solder to soften and the teeth on the bit to close inward. Circulation was restored and about 2 in. of melt was trapped in the bit. Sulphur from the outgassing melt was also deposited on the bit.

Gas samples were afterwards collected by John Naughton of the University of Hawaii, Wayne Ault of the U.S. Geological Survey, and me. It was also found that melt samples could be obtained by attaching a 'shoe', a tapered cylinder, to the drill rods and driving this into the melt by hand. The core melt thus obtained could then be tapped out of the shoe. At 20.4 ft. further removal of melt by sampling did not deepen the hole. In less than two days the lava had risen from 20.4 ft. to 18.7 ft. deep in the hole. The hole was then sealed with a capped stainless steel pipe. A platinum-platinum 90 per cent rhodium 10 per cent thermocouple package was installed in the pipe to study the cooling history at three points in the lava lake crust.

Difficulties were encountered in obtaining temperature data as the hole was drilled. Fig. 1 is a plot of the most reliable measurements. These measurements are preliminary and require further evaluation. The peak temperature of 1,064°C. was obtained with an optical pyrometer and is probably a little low due to some gas in the hole.

Fig. 1. Measured temperature as a function of depth of the hole. ●, Chromel-alumel thermocouple; △, platinum-platinum 90 per cent rhodium 10 per cent thermocouple; □, optical pyrometer; ▲, platinum-platinum 90 per cent rhodium 10 per cent 18 days after completion of hole

It is planned to run complete chemical and petrographic analyses on the core and melt samples. The gas samples will be analysed, oxygen-16 : oxygen-18 ratios will be determined on the water and carbon dioxide gases, and the deuterium and tritium content of the water will be measured. These will be compared with local rain and ocean water to determine whether they are primary gases or not. The hydrogen-water ratio of the gases and the ferrous oxide : ferric oxide ratio of the melt and crust samples will also be determined. Thermal conductivity will be measured on the crust samples, making possible a calculation of thermal conductivity of the crust material as a function of temperature and a calculation of heat-flow through the crust.

This work was conducted as part of the Plowshare Program supported by the U.S. Atomic Energy Commission. Details of the experiment, the results of the forthcoming analyses, and their implications will be published elsewhere.

Thanks are due to Dr. G. C. Kennedy of the University of California at Los Angeles, Dr. G. H. Higgins, and others at the Lawrence Radiation Laboratory for their interest in the investigation; Dr. G. A. Macdonald of the University of Hawaii and W. P. Bennett from this Laboratory for their participation; members of the Hawaiian National Park Service and the U.S. Geological Survey Volcanological Observatory for their kind co-operation; and the drilling contractor, Nat Whiton from Honolulu, Hawaii.

GEOLOGY

Occurrence of Hydromagnesite in Sediments in South Australia

A PROMINENT feature of the South Eastern Province of South Australia is the system of lagoons associated with a long narrow arm of the sea, the Coorong, formed by a receding and partly resubmerged coastline. In some of these lagoons, as well as in the shallow waters at the closed end of the Coorong, dolomite-calcite sediment is forming, apparently by direct precipitation from saline waters^{1,2}.

Recently, C. von der Borch examined the sediment in a lagoon which lies within a few hundred yards of the eastern edge of the Coorong from which it is separated by a belt of low sand dunes. Macroscopically the sediment closely resembles other fine-grained carbonate sediments of the region but was found in its surface layers to consist essentially of aragonite and hydromagnesite in approximately equal amounts. The proportion of hydromagnesite decreases with depth and has not been detected below about 9 in., at which level the sediment is essentially aragonite. Calcite then appears, and the proportion of aragonite diminishes to zero, after which dolomite makes its appearance. At a depth of 2 ft. the sediment consists essentially of calcite and dolomite.

This mode of occurrence of hydromagnesite appears to be unusual, and is of particular interest in South Australia where the origin of sedimentary magnesite associated with dolomite of Proterozoic age has presented a problem. These rocks occur mainly in the Flinders Ranges and have recently been described by B. G. Forbes³. They show sun-cracks and ripple marks, and may have been formed by sedimentary processes similar to those in progress in the shallow lagoon in the South Eastern Province to-day.

Work on the geochemistry and mineralogy of the hydromagnesite sediment is proceeding.

OCEANOGRAPHY

Occurrence of *Calanoides carinatus* (Kröyer) in the Plankton of the Gulf of Guinea

THERE are fairly regular fluctuations in the temperature of the water of the Guinea Current off the coast of tropical West Africa between Cape Palmas and Lagos^{1,2}. Minimum temperatures are usually observed during the months of July–October. The fall in temperature is most pronounced in the coastal waters between Accra and Lome. Observations carried out by Howat², from June 1943 until September 1944 at a station about $1\frac{1}{2}$ miles from the shore off Accra, showed that the variation in the temperature of the surface water exceeded 10 deg. C., with minima of 19.0° C. during August 1943 and 19.8° C. during August 1944. This colder water was rich in phosphate and its appearance was accompanied by a flowering of diatoms.

During 1952, the R.V. *Cape St. Mary* made a series of exploratory fishing voyages in the coastal waters between Cape Verde and Fernando Po for the West African Fisheries Research Institute. During these surveys the opportunity was taken to obtain information on the quantity and composition of the zooplankton. Hydrographic and plankton sampling was carried out along a series of transects running from the coast to the edge of the shelf. At each station water samples for temperature and salinity determinations were taken at standard depths, and plankton samples were collected with 18-in. diameter plankton nets (20 meshes per cm.) hauled vertically from the bottom to the surface.

The stations worked included seventeen between Fernando Po and Lagos, during July, and twenty-five between Lagos and Cape Three Points in August. The distribution of surface temperature during the survey is illustrated in Fig. 1a. There was a decrease in temperature from east to west with a maximum of 27.8° C. between Fernando Po and the mainland and a minimum of 22.1° C. close to the coast off Cape Three Points. Greatest quantities of zooplank-

+, Present.

ton were found along the edge of the shelf in the region where the surface temperature was less than 25° C. These higher zooplankton displacement volumes were mainly due to large numbers of the large copepod, *Calanoides carinatus* (Kröyer), the distribution of which is shown in Fig. 1b. The majority of individuals were stage V copepodites; but a few adults were also observed at most stations. In contrast to the usual colourless appearance of preserved copepods from tropical regions, these specimens of *C. carinatus* contained orange globules of oil.

Table 1 illustrates the relative abundance of the more common copepod species in hauls taken from 100 m. to the surface along three sections of the shelf. *C. carinatus* was the dominant copepod between Cape Three Points and the Volta, but was not recorded between Lagos and Fernando Po where the

Fig. 1. a, Stations, surface temperature and zooplankton displacement volumes; b, distribution of *Calanoides carinatus*

zooplankton was sparse and no species clearly dominant.

In the Atlantic, *C. carinatus* is widely distributed between 47° N. and 37° S., although it is by no means a common species³. It was not recorded by Scott⁴ in his monograph on the Entomostraca of the Gulf of Guinea collected during the cruise of the *Buccaneer* in 1886 although this expedition covered much the same area as that sampled by the *Cape St. Mary* sixty-six years later. However, the results of this latter survey suggest that the distribution of the species is, in some way, related to colder surface water. The cruise of the *Buccaneer*, between Cape Three Points and Lagos, took place during January and February and Scott's records showed that surface temperatures at this time exceeded 27° C.

The distribution of zooplankton along this coast is of interest in connexion with the fishery for *Sardinella aurita* Valenciennes. This fish is rare in Nigerian waters but abundant off the coast of Ghana⁵, where high landings correspond closely to the period when the surface temperature is below 25° C. (ref. 6). Recent work on *S. aurita* has shown that its chief food groups are copepods together with other planktonic Crustacea, and that aggregations are often closely related to the available food supply^{7,8}.

Internal Waves and Waves of Sand

A DESCRIPTION has been given of some large sand waves on La Chapelle Bank which lie parallel to the general direction of the edge of the continental shelf¹. They occur within a zone about 10 miles wide, have a mean separation of 2,800 ft. and are up to 40 ft. high. Berthois² believes them to be fossil ridges while Cartwright³ has shown in some detail how they could be formed by stationary waves, which develop in the thermocline as the tidal streams, moving landwards, feel the constraining influence of the shelf. These would be equivalent to lee-waves found on the down-wind side of a mountain.

Internal waves (not necessarily stationary) of similar amplitude and wave-length to the sand waves are the only possible explanation of the abnormal oscillation of a scattering layer shown in Fig. 1. The pattern was recognized on August 15, 1959, and on August 3, 1960, when R.R.S. *Discovery II* passed over the bank using a 36-kc./s. narrow-beam echo sounder. The new information appears to

Fig. 1. An echo sounder record over La Chapelle Bank, showing internal waves (revealed by a well-developed scattering layer) overlying sand waves of similar size. The record was taken approximately at right-angles to the crests of the sand waves and its mid-point is situated about 8 miles from the oceanward side of the bank. (The vertical white stripes are due to defective recording paper)

support Cartwright's theory, and adds interest to the study of the internal waves in the western approaches to the English Channel.

METALLURGY

'Intrinsic Stress', σ_0 , in the High-Temperature Behaviour of Metals

THE governing relation between strain ϵ and stress σ for the behaviour of metals at temperatures above about half the melting point seems to be of the form :

$$\frac{d\epsilon}{dt} = \frac{1}{E} \frac{d\sigma}{dt} + M \sinh \frac{\sigma}{\sigma_0}$$

where E is the elastic modulus and M is a function of temperature¹. The quantity σ_0 , which has the dimensions of stress, is a constant for a metallurgically stable material and is independent of temperature. Its value does, however, vary considerably, depending on the presence of impurities or of alloying material.

The constancy of σ_0 with temperature has been a mystery, but a recent paper² has perhaps thrown some light on the matter. In this paper the authors relate creep to the presence in the metal of so-called 'bad sites' which impede the free movement of dislocations. These bad sites are provided by crystal imperfections, impurities, and alloying elements. At these sites there develops a stress concentration which is relieved by diffusion of matter in the vicinity of the site. Such a movement of matter permits the activation energy for creep to be rationally identified with the activation energy for self-diffusion in agreement with experimental observations.

The authors, who call σ_0 an 'intrinsic stress', have attempted to compute its value on the basis of the postulated material with its bad sites. They find that :

$$\sigma_0 = \frac{nk\theta}{v} \varphi^2$$

Table 1. COMPUTED VALUES OF φ

Material	θ ($^{\circ}$ K.)	V (c.c.)	$\bar{\sigma}_0$, psi	c	b	$\sigma_0 = \bar{\sigma}_0 (1 + cb)$, psi	$\sqrt{\frac{V}{\theta}} \sigma_0$	σ	Reference for value of σ_0

* Annealed 30 min. at 733° K.; mean grain diameter, 0.21 mm.

† Mean grain diameter, 0.25 mm.

where n is the order of the highest vibrational level which is sufficient to avoid holding up a dislocation (since this communication is concerned with elevated temperatures, n is taken as 3); k , Boltzmann's constant, 1.37×10^{-16} erg/sec.; θ , the Debye temperature, $^{\circ}$ K.; v , the volume per atom (c.c.); φ , the mol fraction of bad sites.

For computational purposes it is convenient to replace v by:

$$v = \frac{V}{N}$$

where V is the atomic volume and N is the Avogadro number, so that:

$$\sigma_0 = \frac{3Nk\theta}{V} \varphi^2$$

For a given material, the intrinsic stress from this formula is thus independent of temperature and varies only with the concentration of bad sites. (It may be noted that σ_0 as defined above is not a stress as such, but is thermal energy per unit volume.)

It is known experimentally that σ_0 increases linearly with concentration of alloying element, at least for small concentrations (see, for example, Fig. 8 of ref. 2). Thus one may write:

$$\sigma_0 = \bar{\sigma}_0 (1 + cb)$$

where $\bar{\sigma}_0$ is the value of σ_0 for the pure metal; b is the concentration of the alloying element; c is a constant.

In recent years, enough values of σ_0 have become known for various materials with sufficient accuracy from phenomenological observations of creep and related behaviour at elevated temperatures to enable these values to be used with confidence in calculations. For the purposes of this communication, these values of σ_0 are considered as known.

The question therefore presents itself in the form: Are the values of φ required to account for these known values of σ_0 reasonable in magnitude? On solving for φ , the mol fraction of bad sites, it is found that:

$$\varphi = \sqrt{\frac{V}{3Nk\theta} \bar{\sigma}_0 (1 + cb)} = 0.01665 \sqrt{\frac{V}{\theta} \bar{\sigma}_0 (1 + cb)}$$

with $\bar{\sigma}_0$ expressed in lb./sq. in. and V in c.c.

Table 1 shows some computed values of φ . In the case of the lightly alloyed metals, the values of V and θ used were those for the pure metals.

Thus for 'pure' metals, out of 15–20 sites, one will be 'bad'. Note that the concentration is about

the same for gamma iron and for lead, two widely different metals. The process of alloying aluminium with 1 per cent of magnesium increases the number of bad sites by about 50 per cent over the number for the original pure metal, while the addition of 2 per cent magnesium doubles the original number of bad sites. For a practical aluminium alloy like 7075 which uses 2.32 per cent zinc, the number of bad sites is apparently as high as one in every six.

It is noticed that at the temperature-range under discussion, the dislocation locking force by chemical interaction of the solute and solvent atoms accounts for a large portion of resistance to dislocation movement (ref. 5). It is known that this locking force is strongly dependent on concentration. Thus it appears that φ may be an expression of the effectiveness of this locking force.

The explanation by the authors of ref. 2 thus seems to furnish a rational picture of the nature of the 'intrinsic stress' σ_0 .

CHEMISTRY

Liquid Chromatographic Separation of Mixtures of Polymers and Mineral Oil

Porath and Flodin¹ have shown that macromolecules in aqueous solutions may be separated from low molecular weight compounds by liquid chromatography using a cross-linked dextran ('Sephadex') as the stationary phase, and water as the mobile phase. It has now been found in these laboratories that polymers dissolved in mineral oil can be separated by a similar chromatographic technique. Small pieces of thin vulcanized natural rubber latex are used as the stationary phase, and a light paraffin hydrocarbon as the mobile phase.

The column used was 21 mm. in diameter, and an 82 cm. length was packed tightly with small pieces of rubber; for convenience pieces of surgeons' finger-cots ('London' brand, supplied by Osborne Garrett and Co., Ltd., 51/55 Frith Street, London, W.1) were used. The area of the pieces of unswollen

Fig. 1. Separation of a mixture of polyisobutene and mineral oil by liquid chromatography using rubber as the stationary phase and *n*-heptane as the mobile phase

rubber varied from less than 1 to about 200 sq. mm., the average size being about 15 sq. mm. The rubber was washed with *n*-heptane before being placed in the column, *n*-heptane being also used as the mobile phase. Under a head of 10 cm. of solvent the flow-rate was about 50 ml. an hr. The sample (about 250 mgm.) dissolved in 5 ml. of *n*-heptane was placed on top of the rubber packing. After all the sample had passed into the packing, further solvent was added, and the flow-rate adjusted to 10–15 ml. an hour. Fractions of 6 ml. were collected, the solvent being evaporated from each fraction and the residue weighed. A graph showing the separation obtained with a mixture of polyisobutene (average molecular weight = 18,000) and mineral oil is shown in Fig. 1. The weight per cent of polyisobutene found was 25.0 compared with 21.9 found by another method; 98.2 per cent of the material placed on the column was recovered. The rubber is slightly soluble in the *n*-heptane; about 0.2 mgm. is found in a 6 ml. fraction.

The separation is presumably due to the swollen rubber acting as a type of molecular sieve. The relatively small mineral oil molecules are able to diffuse into the rubber and are thus delayed during their passage through the column. This explanation is supported by Hill and Munsell's² observation that mixtures of polymers and mineral oil dissolved in light paraffin hydrocarbons can be separated by dialysis using a rubber membrane. Other types of polymers in solution in mineral oil have also been separated.

Decomposition of Water by Light

WE wish to direct attention to two simple cases in which the decomposition of water (or some other oxidation-reduction reaction) can be effected by light of practically any wave-length, and which may play some part in Nature^{1,2}.

The experimental details of these arrangements have already been described^{3,4}. A novel aspect of these experiments is that an organic crystal acts as a photovoltaic and a photoconductive device. In our case, an anthracene crystal was placed between, and separated, two 1 *M* sodium chloride solutions, which acted as transparent electrical contacts to each face of the crystal. These solutions were then connected to each other by an external wire. A current flowed in the external circuit when the crystal was illuminated on one side by 3650 Å. light, as a result of the production of a photo-voltage.

If the crystal had merely been immersed in the salt solution, with no external wires, there would still have been a flow of current through the salt solution, producing in this case hydrogen at the illuminated face and oxygen at the unilluminated face. In other words, the suspension in a salt solution of material capable of exhibiting a photovoltaic effect, and the subsequent illumination of this material alone will lead to the decomposition of the water into hydrogen and oxygen. The wave-length at which this will occur will depend entirely on the action spectrum of the photovoltaic material.

This decomposition of water is, of course, simply an electrolysis, which will take place even at voltages much smaller than the decomposition potential of 1.7 volts, a fact which is sometimes overlooked. More important is the fact that in our case no special photovoltaic device containing a *p-n* junction or special electrodes was necessary for such a decomposition. The pure material, in contact with water, and exposed to strongly absorbed light, will develop a photovoltage, a current, and consequently will decompose water. This voltage is produced by an internal concentration gradient of charge carriers, which is brought about by the inhomogeneous excitation of the organic material. The light is practically completely absorbed in a thin layer adjacent to the illuminated side of the organic material. No special layers and no asymmetrical electrodes are required. This is the first process to which we wish to direct attention.

The second process we envisaged is quite different and uses a chemical reaction plus light. If the electrodes in the arrangement described above are asymmetric, as would be the case if the composition of the electrolyte were different on both sides of the organic material, or if the two faces of the crystal were different from each other, an electrochemical potential would be set up across the crystal; but only an extremely small current would flow in the dark as long as the organic material is non-conductive. If now the organic material is illuminated with light that is either uniformly or inhomogeneously absorbed and thus become photoconductive, a current will flow driven by the electrochemical voltage, and this current would decompose the water. Here the effect of the light is only to make the organic material conductive. Of course, both the photovoltaic and the conductive effects could occur in the same unit and the respective currents produced could either add or subtract, depending on the relative polarity of the photovoltaic and electrochemical potentials.

The fact that a pure organic material suspended in water can decompose the water under the action of strongly absorbed light should be an important consideration in those theories which propose the intervention of an electronic mechanism in the early stages of photosynthesis⁶. It would be expected, of course, that in Nature the photosensitive material would be more highly adapted and efficient than in our laboratory experiment.

The Concerted Mechanism in Acid-Base Catalysis

THE velocity, v , of reactions which exhibit general acid-base catalysis in carboxylate buffers is generally assumed to conform to the equation:

$$v = k_W[H_2O] + k_H[H_3O^+] + k_{OH}[OH^-] + k_{HA}[HA] + k_A[A^-] \quad (1)$$

where the various catalytic constants, k , are differentiated by their subscripts. However, Dawson and Spivey¹ reported in 1930 that the quantitative description of the rate of enolization of acetone, as measured by its iodination in acetate buffers, required an additional cross-term $k_X[HA][A^-]$. The experimental result was substantiated in 1953 by Bell and Jones², who also found similar cross-terms, which may account for up to 20 per cent of v , for trimethylacetate and glycolate buffers. These data are widely considered to be the sole evidence^{3,4} for the occurrence in aqueous solution of a catalytic mechanism, which requires the simultaneous presence of an acid and a base in the transition state complex. The process has been variously described^{3,4} as 'concerted', 'synchronous', 'push-pull', 'ternary' (with reference to the hypothetical number of species in the transition state) and 'bimolecular' (with reference to the hypothetical number of catalytic molecules).

Although Dawson and Spivey¹ appreciated that the kinetic data are consistent with the formation of the hydrogen diacetate ion, HA_2^- , in aqueous solution, the possible existence of this species has been repeatedly discounted⁴⁻⁶. Preliminary reports⁷ of the existence of the hydrogen diacetate ion and three homologues in a 3 M sodium ionic medium at 25° C. have been given elsewhere. Values of the association constants for the relevant reactions:

under these conditions are given below.

Acid	log K_{11}	log K_{12}	log K_{22}	
HOCH ₂ CO ₂ H	3.920 ± 0.005	-0.53 ± 0.02	3.16 ± 0.03	(J. D. E. Carson)
MeCO ₂ H	5.014 ± 0.009	-0.34 ± 0.03	4.63 ± 0.01	(D. L. Martin)
Me ₂ CCO ₂ H	5.327 ± 0.005	~ -0.14	~ 5.33	(J. J. Clarke)

The original potentiometric evidence for the above equilibria in the acetate system has now been substantiated by calorimetric titrations, and the enthalpies and entropies of association have been calculated⁸. The analogous equilibria have also been characterized potentiometrically in eleven other monocarboxylate buffer systems^{7,9}.

As the concept of an inert ionic medium¹⁰, which effectively controls activity coefficients, has not been generally accepted, it may be noted that dimerization constants, referring to the conventional thermodynamic standard state in aqueous solution, have also been reported¹¹ for seven monocarboxylic acids. If our general conclusion that the first acid dissociation constants of the monomeric and dimeric acids are of the same order of magnitude be accepted, then it may readily be confirmed that appreciable concentrations of HA_2^- ions do indeed exist in concentrated buffers.

Accordingly, there is no unambiguous experimental evidence for the concerted mechanism in aqueous solution. Dawson and Spivey's original hypothesis¹ that HA_2^- ions are catalytically active is simpler than the hypothesis of a bimolecular catalytic process and a ternary transition state complex.

The term k_X may readily be shown to equal k_{HA_2} , K_{12} . On the reasonable hypothesis that the secondary salt effect is zero for reaction (3), we may combine our values of K_{12} with Bell and Jones's catalytic constants². We find $10^4 k_{HA}$, $10^4 k_A$, $10^4 k_{HA_2}$ to be 5, 15, 44 for acetate; 4.4, 25, 64 for trimethylacetate; and $10^4 k_{HA_2} \approx 35$ l.mole⁻¹ min.⁻¹ for glycolate at an ionic strength of 0.2 and 25° C. Hence, the proton bismonocarboxylate ions appear to be more effective catalysts than the monomeric acids and carboxylate ions in enolizing acetone. Bell and McCoubrey¹² have reported that the iodination of acetone is also catalysed by the analogous ion, HF_2^- , which they consider to function as an acid catalyst. Correlations of the available data suggest that the HA_2^- ions are functioning as base catalysts. However, they are more effective than would be expected on the basis of the Brönsted relationship for the monomeric bases A^- . It may well be that they are really polyfunctional catalysts, and that the transition state complex has the cyclic structure proposed by Swain and co-workers³.

Finally, it may be stressed that equation (1) can only be valid for very dilute buffers. For concentrated buffers, (1) might be expected to contain not only the cross-term under discussion, but also a further term $k_D[HA]^2$. The concentrations of the dimeric monocarboxylic acids H_2A_2 in concentrated buffers with a high ratio of acid to salt are of comparable magnitude to the concentrations of the HA_2^- ions in 1:1 buffers. The dimers are, moreover, in the open form in aqueous solution and not cyclic^{7,8}. A complete analysis of more extensive and precise

kinetic data would follow the principles outlined elsewhere¹³.

Spectra of Tetrahedral Inorganic Complexes

In the course of work on the spectra of tetrahedral inorganic complexes we have obtained two important types of information, both of which are specially significant for the interpretation of the physical properties of these complexes. The first is the magnitude of the ligand field appropriate to these complexes, and the second is the nature of the inorganic complex-solvent interactions.

Following the recent work of Gill and Nyholm¹, it is now possible to obtain authentic simple tetrahalogeno-complexes of manganese, iron, cobalt and nickel. These have been shown² to be essentially tetrahedral except possibly for some slight distortions which are not important to this communication. It proved, however, somewhat more difficult than anticipated to obtain the spectra of these complexes because of the large solvent-complex interactions which were observed in different supposedly 'inert' organic solvents such as nitromethane, dimethylformamide (DMF), dimethyl sulphoxide (DMS) and dimethylacetamide (DMA).

Even nitromethane solutions of the CoCl_4^{2-} ion (with the triphenylmethyl arsonium cation) show departures from Beer's law which are due to the presence of such species as $\text{CoCl}_{4-n}\text{X}_n$, X being a solvent molecule, and for solutions of the NiCl_4^{2-} complex the degree of solvation is very large. Not only tetrahedral species occur, however, for in dimethylformamide as solvent there is an octahedral-tetrahedral equilibrium which lies almost entirely on the octahedral side for solutions of the $[\text{NiCl}_4]^{2-}$ complex and on the tetrahedral side for the analogous manganese, iron and cobalt complexes. In dimethyl sulphoxide the nickel complex is present entirely as the octahedral form.

The complexing power of these solvents is such that we have been able to isolate complexes of many types, including $[\text{M}(\text{DMF})_6](\text{ClO}_4)_2$ and $\text{MCl}_2(\text{DMF})_2$, and, by studying the effect of chloride ion addition to the octahedral perchlorate, we have been able to determine the extent of solvation. This has previously been done in alcoholic solutions^{3,4}, and recently

some complexes with dimethyl sulphoxide have been isolated⁵, but the equilibria in non-hydroxylic solvents have not previously been understood.

Briefly, on addition of triphenyl methyl arsonium chloride to $[\text{Co}(\text{DMF})_6](\text{ClO}_4)_2$, the latter is at first transformed into the species $\text{CoCl}_2\text{DMF}^-$ without any other detectable intermediates; and addition of further chloride, up to a molar excess of about 10:1, converts a large part of this into CoCl_4^{2-} .

The behaviour of $[\text{NiCl}_4]^{2-}$ in dimethylformamide solution (and dimethylacetamide and dimethyl sulphoxide) is much more complicated, since nearly all the solute is present as an octahedral form in the absence of excess chloride. The equilibrium is strongly dependent on temperature, higher temperatures favouring the various, presumably tetrahedral but perhaps square, species; there are at least three and possibly four of these which occur in the solution, together with at least two octahedral complexes. Complete analysis of the spectrum is very difficult, however, because the spectra of the two stereochemical species overlap one another considerably, as do also the various tetrahedral spectra. Even in nitromethane, which is found to be the least solvating medium, the ϵ_{max} values of $[\text{NiCl}_4]^{2-}$ solutions are increased by nearly 30 per cent when excess chloride ion is added and a spurious band is eliminated at the same time.

The above synopsis emphasizes the need for caution in ascribing absorption bands of complexes in solution to any particular species, unless the absence of solvation has been clearly demonstrated.

The spectra of the tetrahedral species yield very interesting information concerning the magnitude of $\Delta (= 10Dq)$ for tetrahedral halide complexes, and in Table 1 we have summarized the results found for the chlorides of manganese¹⁴, cobalt and nickel.

Table 1

Con- fig. of free ion	Com- plex	Absorption maxima (cm. ⁻¹)			Δ in cm. ⁻¹
		Experiment		Calculated	
d^5	MnCl_4^{2-}	21650	22520 23200	21850 22350 23150	2650
			23420 26550 27330	(23420) 27500 27200	
			28090 35550 37100	(28090) (35550) 35730	
d^7	CoCl_4^{2-}	75800	14415 14965	36450	3250
		15580	15745 16295	3250 (5850) 14900	
d^8	NiCl_4^{2-}	?	7550 14180	4000 (7500) 14200	3650
		15170	16255		

Note. In Table 1 the figures in brackets are used as parameters to calculate the other frequencies. Also, except for manganese, all the transitions listed are spin allowed. It will also be noted that only one visible band is listed instead of many for the cobalt and nickel complexes. The other bands are usually (ref. 6) assigned as partner spin-orbit components of the main band, but for cobalt there are too many of them, and in both cases they are too far apart (ref. 7) to be due simply to this, so that there are still features requiring explanation.

Some rough estimates of Δ for tetrahedral halides of manganese, cobalt and nickel have been given previously¹⁰⁻¹³, but these have been based either on incomplete experimental evidence or else upon spectra which have been erroneously ascribed to the assumed species.

Thus we have been unable to confirm the usually quoted^{10,11,15} value of 6,300 cm.⁻¹ for the ${}^4\text{T}_1(\text{F}) \leftarrow {}^4\text{A}_1(\text{F})$ transition in CoCl_4^{2-} . The infra-red spectrum has been examined in this region by Dr. C. Barraclough, who finds a very broad band with its maximum in the range 5,800-5,500 cm.⁻¹, but at least below 6,000 cm.⁻¹. Such a value leads to a notable

reduction of Δ from the 3,750 cm^{-1} provisionally estimated by Orgel¹⁰ and the 3,500 cm^{-1} used by Ballhausen and Jorgensen¹¹. The molecular extinction coefficients given by Orgel¹⁰ are also too large by a factor of five.

We have also been unable to confirm the spectrum claimed¹² for NiCl_4^{2-} , which was based on bands found in the spectrum of a complex melt; we consider that the melt spectrum belongs to some other (perhaps essentially square or tetrahedral) species of nickel halide, since it closely resembles a spectrum we obtained when anhydrous nickel chloride was dissolved in dimethylformamide, dimethylacetamide or dimethyl sulphoxide. The spectrum of the NiCl_4^{2-} species in a 'Nujol' mull has one broad band with a maximum between 7,500 and 7,600 cm^{-1} , and on simple crystal field theory it is impossible to account for a band at that energy unless a value of Δ larger than 4,000 cm^{-1} is used. From other compounds this seems too large, and it can be reduced to about 3,650 cm^{-1} if the complete treatment including spin-orbit interaction⁷ is used for the calculations. Even this value seems large, and it may be that there are relatively large non-cubic components of the perturbing field in this molecule because of departures from a perfectly tetrahedral structure.

The values of Δ for cobalt and manganese are close to one-third the value of $\Delta(\text{octahedral})$ for the hexahydrates. If, as has been suggested⁸, the Dq for Cl^- is only 75 per cent that of water, then the theoretical ratio of 4/9 between the octahedral and tetrahedral Δ values would be well supported by experiment.

A complete report of this work is now being prepared for publication.

BIOCHEMISTRY

A Possible Biochemical Mechanism for Memory

In a recent paper¹, Leo Szilard has shown that a system consisting of an enzyme, an enzyme-forming apparatus and a repressor may be able to exist in two stable states, provided the combining energies between the various components of this system lie within certain ranges of magnitude. The two stable states which can exist contain either high or low

concentrations of the enzyme. If the concentration of the enzyme or the repressor is changed by external manipulation, the system returns to one or the other of the stable states. Such a system was termed 'para-constitutive' by Szilard, and its possible biological significance in differentiation and antibody formation² was suggested by him.

I should like to direct attention to another possibility, namely, that a para-constitutive system, the components of which are at this time beyond conjecture, may constitute the unit of memory in the brain. A change from one to the other of the two stable states would correspond precisely to the binary memory components used in computers. Since a human brain cell may contain as many as 10^6 genes, as estimated by Szilard for other human cells, a very large number of binary units per brain cell seem possible. It appears conceivable that one might obtain experimental information on the existence of such systems by the careful analysis of brain constituents as a function of the number of memory impulses to which the brain was exposed. A brain exposed to a large number of sensory stimuli would be expected to have different concentrations of the components of the postulated system from a brain carefully shielded from such stimuli.

I should like to suggest that 'para-constitutive' systems may have numerous other biological applications, and that the recognition of their existence appears to be one of the most important biological hypotheses made in recent times.

Heterogeneity of Fatty Acids from Royal Jelly

THE presence of hydroxy fatty acids as the major component of the lipid portion of royal jelly was indicated many years ago by Townsend and Lucas¹ and was confirmed recently by Butenandt and Rembold². The latter authors characterized the major component as 10-hydroxy-2-decenoic acid. A *trans* configuration has been assigned to the double bond^{3,4}. This unusual fatty acid has been found also in the food of worker bee larvae² and in the mandibular glands of worker bees^{3,5}, but appears to be absent from pollen and other bee food. Unusual biological activity has been ascribed to the substance by Blum *et al.*⁶ and by Townsend *et al.*⁷.

Several chromatographic methods have been employed in our Laboratories for a careful examination of the chloroform-soluble portion of lyophilized royal jelly. The results have revealed that the lipid portion is a mixture which is resolved with difficulty and is somewhat more complex than has been previously supposed. A large fraction of the royal jelly lipids consists of free fatty acids. Chromatography of the chloroform extract on a silicic acid adsorption column separated the major acidic components into three fractions. The first of these consists of decanodioic acids, the second consists of several monohydroxy monocarboxylic acids, and the third consists principally of dihydroxy monocarboxylic acids. Each fraction was separated further by silicic acid partition chromatography, paper chromatography, and chrom-

atography of the methyl esters in the vapour phase employing a silicone stationary phase.

The decandioic acid fraction consists of roughly equal parts of two acids that were separated by partition chromatography using 1 *M* citrate buffer, pH 5.75, on silicic acid as the stationary phase and a gradient of butanol-1 in chloroform as the moving phase. The methyl esters were also separated by vapour-phase chromatography. One of these compounds had chromatographic properties and melting point identical with those of sebacic acid. The other compound had properties identical with those reported for 2-decen-1,10-dioic acid. On reduction with hydrogen in the presence of platinum it gave sebacic acid. This confirms the work of Brown and Freure⁴, who also reported the presence of these substances in royal jelly.

The hydroxy acid fraction contained at least six components, as judged by vapour-phase chromatography of the methyl esters. A major component that constitutes at least 80 per cent of this fraction was obtained in a fairly high state of purity (95 per cent or greater homogeneity, judged by vapour-phase chromatography) by careful chromatography on silicic acid. This material melts at 61.5–62° C. (corrected) and on reduction with platinum and hydrogen gives more than 80 per cent yield of 10-hydroxydecanoic acid (m.p. 73.5–74.5° C., mixed melting point with authentic compound 73.5–75° C.). Mixtures of this acid, which is assumed to be 10-hydroxy-2-decenoic acid, with the other naturally occurring constituents of the hydroxy acid fraction melt in the range from 53° to 60°.

A second component, comprising about 5 per cent of the hydroxy acid fraction, has the chromatographic properties of the saturated compound, 10-hydroxydecanoic acid. A small amount of this material was separated from the unsaturated acids by a modification of the method of Jantzen and Andreas⁷. The somewhat impure compound melted at 71.5–73.5° C., and a mixture of this material with the authentic compound melted at 72–75° C.

The third crude fraction yields on recrystallization a material that melts at 98–101° C. Analysis gives the formula C₁₀H₂₀O₄ and the neutral equivalent is 208 (calculated 204). The infra-red and ultra-violet spectra indicate a saturated carbon chain. Vapour-phase chromatography of the methyl ester indicates that this consists of three very similar and not completely separable components. The major compound constitutes about 85 per cent of the mixture. Although it has not been possible to separate the components, and only small amounts of material are available, preliminary work involving chromic acid oxidation, dehydration and acetylation indicates that the principal compound is a dihydroxydecanoic acid containing a hydroxyl group in the β -position to the carboxyl group. The other hydroxyl group does not appear to be terminal.

The complexity of the mixture of fatty acids in royal jelly indicates the need for caution in interpreting the results of experiments on the biological activity of crude samples presumed to consist of 10-hydroxy-2-decenoic acid. Many of the fatty acids have similar polarity and cannot be removed by repeated recrystallization. The presence in this mixture of a homologue of traumatic acid (duodecen-1,12-dioic acid), which is known to have a profound effect on cell growth, serves to emphasize the care that should be exercised in such experiments.

The fact that all fatty acids thus far identified in royal jelly contain ten carbon atoms and that the queen substance, recently characterized and synthesized⁹, also is a decenoic acid (9-oxo-2-decenoic acid) probably indicates a common biogenetic origin of these compounds. It is tempting to speculate that some component of the diet fed to the queen by her workers is converted in her body to the queen substance. However, no evidence for this is now available.

Experiments have been performed using isotopically labelled compounds in an effort to demonstrate formation of hydroxy fatty acids in worker bees. Sodium acetate-1-¹⁴C and sodium stearate-1-¹⁴C have been fed to worker bees and included in an incubation medium with excised mandibular glands. In both cases considerable radioactivity was detected in lipid extracts of the mandibular glands, but the hydroxy acid fraction did not become labelled.

The details of these experiments will be reported elsewhere. This work was supported by research grants from the U.S. Public Health Service and the National Science Foundation.

Malic Acid Synthesis in *Escherichia coli* and its Inhibition by Cocaine

It has been shown that cocaine specifically inhibits the synthesis of citrate in yeast¹ and in animal tissues², and that other local anesthetics possess a similar specificity of action in blocking cellular respiration³. An enzyme, malate synthetase, which catalyses the synthesis of malate from acetate and glyoxylate in a manner analogous to the formation of citrate from acetate and oxaloacetate, has since been discovered⁴ and has been shown to participate in some micro-organisms in a modified citric acid cycle which has been described as the glyoxylate cycle⁵.

In view of the analogous functions of malate synthetase and citrate synthetase, it occurred to us that cocaine might have a similar effect on both these condensing enzymes and would thus inhibit the synthesis of malate. Such inhibition has now been demonstrated in *Escherichia coli*, and it is of interest to compare the effects of cocaine on the two enzyme systems under similar conditions.

We find that, whereas citrate accumulates in an aerated suspension of washed baker's yeast in 0.2 *M*

magnesium acetate⁶, malate accumulates in *E. coli* under these conditions. The bacterial cell suspensions, with and without cocaine, were aerated at pH 7 and 37° following the procedure previously described for the experiments with yeast². Samples were withdrawn at intervals for the estimation of malic acid by the fluorimetric method of Hummel⁷, or of citric acid by the colorimetric method of Natelson, Pincus and Lugovoy⁸. In a series of experiments in which malic acid synthesis occurred at the rate of 20–30 $\mu\text{gm./ml. cell suspension/hr.}$, cocaine (0.001 M) inhibited by 79 ± 4 per cent. Citric acid synthesis in yeast under similar conditions was inhibited by about 70 per cent¹.

No citric acid synthesis occurred in the *E. coli* suspension, which suggests that a glyoxylate cycle in this organism may function independently of citric acid metabolism and would thus differ from the glyoxylate cycle of Kornberg and Krebs. We are investigating this possibility and extending the work with cocaine to a study of its action on the isolated enzymic systems.

We wish to thank Dr. N. F. T. Crowley of the Royal Free Hospital for supplying the pure strain of *E. coli* used in these experiments.

β -Lactoglobulins in the Urine of the New-born Suckled Calf

IMMUNOLOGICAL, electrophoretic and ultracentrifuge data have been presented which show that certain proteins present in bovine colostrum contribute to a transient proteinuria which persists in the suckled calf for about 30–40 hr. *post partum*^{1,2}. The work reported here supports previous findings, but emphasizes more specifically that it is the β -lactoglobulin in the colostrum which is absorbed from the gut along with the immune lactoglobulin, during the period of gut permeability immediately *post partum*, which is afterwards selectively cleared from the circulation probably by glomerular filtration by virtue of its low molecular weight and gives rise to a β -lactoglobulinuria. The immune lactoglobulin carrying the antibody activity is largely retained.

Aschaffenburg and Drewry^{3,4} have shown that there are two lactoglobulins A and B which can be identified by their differing electrophoretic mobility and that the presence of either one or both is determined genetically. We have confirmed these observations using starch-gel electrophoresis and have used these characteristics to identify further and confirm the major contribution of β -lactoglobulin to the urine protein of the new-born suckled calf.

Fig. 1. Boundary electrophoretic patterns (ascending side only, phosphate buffer pH 8, $I = 0.2$) for rennin milk-whey proteins showing β -lactoglobulins (A, B and AB) at (i), (ii) and (iii), respectively, and at (i), (ii) and (iii) after the addition of a bovine serum albumin fraction to equal approximately the concentration of the β -lactoglobulin.

In rennin-prepared milk-whey usually no separation of the mixed β -lactoglobulin AB was obtained by boundary electrophoresis, and bovine serum albumin could only be distinguished as a separate component from the slower β -lactoglobulin B (Fig. 1).

In starch-gel electrophoresis, on the other hand, the β -lactoglobulins A and B were easily separable and in addition both could be distinguished from serum albumin, which showed a slightly slower mobility (Fig. 2a). Therefore colostrum were selected in which the β -lactoglobulin had been identified as either A, B or AB and were fed to new-born calves.

Calves 1, 2 and 3 were fed colostrum containing AB, A and B β -lactoglobulin respectively. Fig. 2b, c and d show an exact correlation between the electrophoretic mobility in starch-gel electrophoresis of the particular β -lactoglobulins fed and the major protein components in the associated urine during proteinuria. The heavily stained slow component (immune lactoglobulin) in the colostrum fed is almost entirely absent from the urine.

Although this method of electrophoresis does not give reliable quantitative data, it is evident that neither the immune lactoglobulin (mol. wt. 180,000)

present at high concentration in the colostrum and after suckling in the serum of the calf, nor, with the possible exception of calf 3, the serum albumin (mol. wt. 68,000) contributes significantly to the proteinuria.

The immune lactoglobulin has been shown to confer a passive antibody protection on the new-born calf, which prior to suckling is agammaglobulinæmic. Therefore its retention by the calf has a survival value, and since it is derived from the maternal serum⁵⁻⁷ it is unlikely to be antigenic. However, the β -lactoglobulin is synthesized locally in the udder⁸

Serotonin (5-Hydroxytryptamine) in the Male Reproductive Tract of the Spiny Dogfish

In elasmobranch fishes, in which fertilization is internal, the caudal portion of the pelvic fin of the male is prolonged to form a stout rod-like copulatory organ or 'clasper'. The clasper is rolled up in a scroll-like fashion, enclosing on its medial side the so-called clasper groove or tube, along which at copulation the spermatozoa pass from the urogenital papilla of the male to the oviducts of the female.

The clasper groove communicates with an accessory organ, located under the skin of the abdomen, which in the shark and dogfish usually takes the form of a muscular sac, the so-called clasper siphon, whereas in the skate it assumes the form of a solid glandular organ, the so-called clasper gland. Leigh-Sharpe¹, who studied in detail the comparative anatomy of secondary sexual characters of elasmobranch fishes, came to the conclusion that the clasper siphon of the Selachii acts as a "reservoir of seawater" which is emptied at copulation by muscular contractions of the siphon wall, and in this way helps to pump the spermatozoa from the clasper groove into the oviducts. Gilbert and Heath², on the other hand, expressed the opinion that the siphons may actually have some secretory function, and contribute a part of the seminal plasma.

The total lack of data on the biochemical properties of the clasper siphon prompted me to study this organ in the spiny dogfish, *Squalus acanthias*, a viviparous aplacental elasmobranch, in which the abdominal siphons are particularly well developed and easily accessible. The siphon sacs of an adult male, caught early in July in the Gulf of Maine, were tapped by inserting through the apophyle the finely drawn-out end of a ball pipette, filled with water, and flushing the siphons with the water. Various chemical reactions were carried out with this fluid, including tests for ergothioneine, which is known to be secreted by male accessory organs of reproduction in certain mammals^{3,4}. In the course of these analyses a strong diazo reaction was observed which, however, was not typical of ergothioneine but resembled other aromatic amines in its behaviour. This observation was followed up by a more extensive study of 25 ml. fluid which had been obtained by flushing the siphon sacs of five male spiny dogfishes. On deproteinization with zinc sulphate and barium hydroxide, and centrifugation, a water-clear extract was obtained, representing a dry weight of 175 mgm. or 7 mgm./ml. This extract, when used in 0.02-0.1 ml. quantities, yielded strongly positive colour reactions with sulphanilic acid and sodium nitrite; Ehrlich's dimethylaminobenzaldehyde reagent; 1-nitroso-2-naphthol; and ninhydrin. At this point, a

Fig. 2. Starch-gel electrophoretic patterns (phosphate buffer pH 7.6) showing at (a) serum albumin fraction and milk-whey β -lactoglobulins AB, B and A, at (b), (c) and (d) colostrum whey fed and derived urine during proteinuria in calves 1, 2 and 3, together with control milk-whey β -lactoglobulin AB and crude serum albumin fraction

and there is some evidence that proteins in this category may be antigenic in some circumstances when exposed to the general body tissues of the host⁶. The rapid elimination of this protein together with the relative unresponsiveness of the new-born to antigenic stimuli could help to avoid the development of sensitivity.

I am indebted to Mr. L. J. Wright for the starch-gel electrophoresis, to Mr. D. Hardman for technical assistance and to Mr. J. Clark for the maintenance and handling of the calves.

Fig. 1. Ultra-violet absorption curve of serotonin in the protein-free extract from the clasper siphon secretion; mercury lines are shown for reference

spectrophotometric analysis was carried out. The ultra-violet spectrum (Fig. 1) obtained with the 1:20 diluted extract in a Bausch-Lomb recording spectrophotometer exhibited all the characteristic features of the spectrum of the aromatic amine serotonin, known also as enteramine or 5-hydroxytryptamine. It possessed a maximum at 275 $m\mu$ and a subsidiary peak at 295 $m\mu$; on alkalinization with sodium hydroxide it exhibited two distinct maxima, at 275 and 325 $m\mu$, respectively. From the optical density observed, and the molecular extinction coefficient $\epsilon = 5.3 \times 10^3$, the serotonin content of the protein-free extract was calculated as 437.5 $\mu\text{gm./ml.}$, or 6.25 per cent of the dry material. A determination based on absorption measurement of the purple-coloured reaction product with 1-nitroso-2-naphthol⁵ gave a closely similar result, 6.38 per cent. Further confirmation of the identity of serotonin was obtained by paper partition chromatography. The chromatograms were run at room temperature for 16 hr. on Whatman No. 1 filter paper, with butanol/acetic acid as the solvent (40 vol. *n*-butanol + 10 vol. acetic acid + 50 vol. water; upper layer used); the spots were located with the following reagents: diazotized sulphanilic acid³, Ehrlich's reagent⁴, silver nitrate, ninhydrin. These reagents revealed spots the R_F value of which was identical with that of pure 5-hydroxytryptamine creatinine sulphate.

Six more male spiny dogfishes became available in August. Three were sexually mature (990–1,280 gm.) and contained numerous spermatozoa in the seminal ducts and the 'seminal vesicles'; their clasper siphons were about 9 cm. long and 1.5 cm. wide. The siphons were opened longitudinally and the undiluted secretion was collected. Each pair of clasper siphons yielded about 250 gm. of a highly viscous, yellowish

fluid, the analysis of which revealed a remarkably high concentration of serotonin, namely, 5.7–7.7 per cent, which corresponds to a content of more than 16 mgm. serotonin per animal. After the removal of the secretion the siphons were washed with water, the tissue ground and analysed for serotonin. Pairs of siphons, weighing 2.8–3.6 gm., contained on the average 0.3 per cent serotonin, that is, about 9 mgm. per animal. Serotonin was absent, or present only in traces, in the sperm removed directly from the seminal ducts and the so-called seminal vesicles, in the contents of the cloaca, and in the liver and testes. The remaining three dogfishes were sexually immature males (275–440 gm.) which contained no spermatozoa in the reproductive tract, and had clasper siphons about 0.5 cm. long, and weighing about 100 mgm. The clasper siphons of these immature males contained 0.017–0.048 per cent serotonin, that is, some 200 times less than found in sexually mature fishes.

Serotonin is known to occur in certain organs, of vertebrates and invertebrates alike, usually in association with the so-called enterochromaffin cells; it is implicated in various vital functions, including cardiac output, blood pressure, pulmonary and renal circulation, and the activity of the central nervous system and the gastrointestinal tract^{7,8}. Serotonin exerts a powerful stimulating influence on the isolated rat uterus, in dilutions 1:100–200 millions⁹; and when administered intravenously to dogs, 1–3 $\mu\text{gm./kgm.}$, it elicits strong uterine contractions, followed by an inhibition¹⁰. The findings concerning the spiny dogfish show that the clasper siphon is a rich source of serotonin, the concentration of which exceeds by many times the values recorded for other animal organs: a fish weighing 1 kgm. contains in its clasper siphons some 20 mgm. of serotonin. The presence of so much serotonin in a secretion which represents an integral part of semen suggests that, in the spiny dogfish in any event, serotonin may play a part in the reproductive process, either by affecting the mechanism of copulation and ejaculation in the male, or by eliciting contractions of the female reproductive tract, thus influencing passage of sperm and fertilization.

I thank the Lalor Foundation for the award of the Senior Lalor Fellowship, Dr. P. S. Galtsoff and Dr. H. W. Graham of the U.S. Bureau of Commercial Fisheries Biological Laboratory for generously placing the experimental animals at my disposal, and colleagues at the Marine Biological Laboratory for friendly co-operation.

Function of Ribonuclease in Germinating Peas

ALTHOUGH ribonucleases have been found in a large variety of tissues of plant, animal and microbial origin, only the crystalline enzyme from bovine pancreas has been studied in detail. This enzyme is known to bring about the degradation of ribonucleic acid by transesterification. In this process, a 5'-phospho-ester residue is split and a new 2'-phosphate ester linkage is formed, giving a 2',3'-cyclic phosphate of a pyrimidine nucleoside as shown (I→II; R_1 = cytosine or uracil; R_2 = adenine, guanine, cytosine or uracil); subsequent hydrolysis of the cyclic phosphate by the enzyme then produces the 3'-hydrogen phosphate of the pyrimidine nucleoside (III)¹. Synthesis of internucleotide linkages has been demonstrated with certain ribonucleases^{2,3} by reversal of the above reaction (II→I), and it has been shown that the specificity of the pancreatic enzyme in the reverse reaction is such that only linkages of the type known to be present in ribonucleic acid are formed⁴. The involvement of ribonucleases in the synthesis of ribonucleic acid has frequently been suggested; but, although the capacity of the enzyme to effect synthesis is not in doubt, it is difficult to obtain direct evidence to support the hypothesis that ribonucleases fulfil a synthetic function in the cell.

Reddi⁵ has found that infection of tobacco leaves with tobacco mosaic virus is accompanied by a substantial increase in the ribonuclease activity of the leaves, and since the virus possesses no independent enzyme systems, it was suggested that synthesis of viral ribonucleic acid occurs at the expense of leaf ribonucleic acid through the action of the leaf ribonuclease. In view of this suggestion, we wish to record our preliminary investigations on the activity of ribonuclease in the early stages of the development of the pea seedling.

We have measured the ribonuclease activity, the percentage of ribonucleic acid and of protein in the cotyledons and in the root and shoot in peas germinating in the absence of external nutrients. The results are shown in Fig. 1. It is seen that in the cotyledons, similar variations with time occur in protein and ribonucleic acid concentrations and in ribonuclease activity. In each case an abrupt change in the curve occurs around the fifth to the sixth day after sowing. Holden and Pirie⁶ examined the ribonuclease of pea seedlings grown in compost and found that activity of the enzyme in the whole seedling increased from the second to the sixth day after sowing and remained constant thereafter until the tenth day when activity began to decrease. These results are not entirely comparable with ours, since in

Fig. 1. Ribonuclease units per plant (1 unit = 1 mgm. pancreatic ribonuclease). □, Total; △, cotyledons; ■, root and shoot. Ribonucleic acid per plant (μmoles P). ×, Cotyledons; ▲, root and shoot. Protein nitrogen per plant (mgm. N). ●, Cotyledons; ○, root and shoot

our experiments no external nutrient was supplied. However, it is significant that the time at which sharp maxima occur in curves I, II and III corresponds closely to the time at which Holden and Pirie observed maximum ribonuclease activity, and it appears that at about the sixth day after sowing a marked change occurs in certain reactions taking place in the cotyledons.

The situation in the growing parts of the plant is quite different from that in the cotyledons. The ribonucleic acid of the root and shoot remains at a very low level until after the acid of the cotyledons has reached its maximum value, after which a slow increase occurs. Whereas in the cotyledons the ribonucleic acid content and ribonuclease activity run approximately parallel, in the root and shoot the appearance of ribonuclease activity precedes the increase in ribonucleic acid content (curves IV and V). Furthermore, the increase in activity occurs at a time when total protein (curve VI) is not increasing in the growing parts.

It is felt that increase in ribonuclease activity at a time when synthesis of ribonucleic acid is taking place cannot be taken necessarily to imply involvement of the enzyme with synthesis, and no conclusions can be drawn regarding the function of the enzyme in the cotyledons from curves II and III, which run parallel both during increase and decrease of ribonucleic acid content. In the root and shoot, however, the appearance of active ribonuclease prior to the increase in ribonucleic acid strongly suggests a synthetic function for the enzyme, since activity increases at a time when there is apparently little or no substrate for the degradative reaction.

So far as is known, nucleoside cyclic phosphates of type II have not been recognized as normal cellular constituents, and it seems likely that, if internucleotide bonds are formed *in vivo* by a reaction of the type II→I, the process is involved not with net synthesis of ribonucleic acid but with the reversible breakdown and re-synthesis. During the early stages in the development of the pea seedling in the absence of external nutrient, the growing organs are dependent on the cotyledons for some cellular materials. We

suggest that in the germinating pea, ribonuclease is involved in the translocation of polynucleotide material by bringing about degradation of ribonucleic acid in the cotyledons and re-synthesis in the root and shoot. This mechanism, since it does not involve nucleoside 5'-polyphosphates as intermediates, could operate without interference with the synthesis of nucleotide coenzymes in the growing parts of the plant.

Mechanism of the Action of Thymidylate Synthetase

It has been postulated¹⁻⁴ that the enzymic synthesis of thymidylic acid from deoxyuridylic acid occurs according to the equations:

Previous evidence that dihydrofolate is a product has been indirect, since it rested on: (1) balance studies which indicated that tetrahydrofolate is a substrate, and that it assumes the role of catalyst only under conditions where it is regenerated^{1,3,4}; (2) isotope experiments in which it was shown that hydrogen isotope from tetrahydrofolate is incorporated into the methyl group of thymidylate⁵.

We have now obtained direct evidence that dihydrofolate is a product of the reaction by experiments with thymidylate synthetase purified 100-fold from sonic extracts of *Streptococcus faecalis* R. Dihydrofolic reductase purified 300-fold from *S. faecalis* R. was used to generate L-tetrahydrofolate in the reaction mixture and the latter compound then reacted with formaldehyde to give methylene tetrahydrofolate, which produced a characteristic absorption spectrum. In the presence of the purified thymidylate synthetase (activity 10 μ moles of thymidylate synthesized/hr./mgm. protein), addition of deoxyuridylylate caused a spectrum change, the rate of which has been used to determine enzyme activity. On completion of the reaction the spectrum was that of dihydrofolate. The product with this spectrum was hydrogenated by reduced triphosphopyridine nucleotide in the presence of the highly specific dihydrofolic reductase and the reduction was inhibited by aminopterin, which is a specific inhibitor of folic and dihydrofolic reductases.

Friedkin and Kornberg postulated⁵ that in the thymidylate synthetase reaction deoxyuridylylate and methylene tetrahydrofolate react to form an intermediate in which a methylene bridge links C⁵ of uracil to N⁵ (or N¹⁰) of tetrahydrofolate. During the course of our work on the purification of thymidyl-

ate synthetase, none of the many fractionations has resulted in even partial separation of activity into the two different enzyme fractions which would be required to synthesize and cleave such an intermediate. When the reaction was followed spectrophotometrically there was no indication of a change in reaction-rate of the kind to be expected if an intermediate accumulated in the reaction mixture. Moreover, two well-defined isosbestic points were observed for the spectrum change, indicating that dihydrofolate was the only new species formed in significant amounts from methylene tetrahydrofolate.

In isotope experiments we have generally used labelled glucose-6-phosphate-³H, glucose-6-phosphate dehydrogenase and triphosphopyridine nucleotide to hydrogenate dihydrofolate in the presence of dihydrofolic reductase to yield L-tetrahydrofolate-³H. The hydrogen transfers proceeded to completion and the entire product was then allowed to react according to equations (1) and (2). The thymidylate formed was degraded to thymine, which was isolated by paper chromatography. The specific activity of the thymine did not differ significantly from that of the hydrogen attached to carbon-1 of the glucose-6-phosphate. The latter was estimated by forming glutamate-³H from the glucose-6-phosphate-³H in the presence of appropriate enzymes and substrates⁶. When tritiated water and unlabelled reduced triphosphopyridine nucleotide were used in a similar sequence of reactions the isolated thymine had only 2 per cent of the specific activity of the water. These results are similar to those obtained by Friedkin⁵ with chemically synthesized DL-tetrahydrofolate, except that in our experiments the transfer of hydrogen occurred without significant dilution, and confirm that one hydrogen of the thymine methyl group is derived from tetrahydrofolate.

This evidence suggests that thymidylate synthetase is a single enzyme and that no intermediate of the type suggested by Friedkin and Kornberg⁵ accumulates in significant amounts, although its transitory formation on the enzyme surface would be consistent with the isotope results and other data.

PHYSIOLOGY

Derivation of an Equation for the Diffusion Potential

AN equation for the potential across a membrane arising from the steady-state diffusion of univalent ions was derived by D. Goldman¹ under the assumptions of a constant electric field and constant ionic mobilities across the membrane. His equation may be written as²:

$$V = \frac{RT}{F} \ln \frac{\sum_{i^+} P_{i^+} C_{i^+} + \sum_{i^-} P_{i^-} C_{i^-}}{\sum_{i^+} P_{i^+} C_{i^+} + \sum_{i^-} P_{i^-} C_{i^-}} \quad (1)$$

where V is the electric potential on the right side of the membrane relative to the left side, C_{i^+} is the concentration of the i th positive ion, C_{i^-} is the concentration of the i th negative ion, P is the permeability of the membrane to an ion, r and l denote the right and left side of the membrane respectively, and R , T , and F have their usual meanings. It is the purpose of this communication to derive, without the use of the above two assumptions, an equation similar to equation (1) in which the permeabilities are replaced by unidirectional rate constants.

H. H. Ussing³ has shown under very general conditions without the use of the previous assumptions that if an ion diffuses across a membrane:

$$\frac{\vec{j}_i}{\overleftarrow{j}_i} = \frac{C_{il}}{C_{ir}} \exp\left(-z_i \frac{FV}{RT}\right) \quad (2)$$

where $\vec{j}_i$ and $\overleftarrow{j}_i$ are the unidirectional diffusional fluxes from left to right and right to left respectively, and z_i is the valence of the univalent i th ion. For steady-state diffusion with no current:

$$\sum_{\text{all } i} z_i (\vec{j}_i - \overleftarrow{j}_i) = 0 \quad (3)$$

The unidirectional rate constants will be defined as:

$$k_i = \frac{\vec{j}_i}{C_{ir}} \quad (4)$$

$$k'_i = \frac{\overleftarrow{j}_i}{C_{il}}$$

The k 's need not be constant, but may actually be functions of the concentrations and electric potential. Elementary algebraic manipulation of equations (2), (3), and (4) then yields the desired relationship:

$$V = \frac{RT}{F} \ln \frac{\sum_{i^+} k_{i^+} C_{i^+} + \sum_{i^-} k'_{i^-} C_{i^-}}{\sum_{i^+} k_{i^+} C_{i^+} + \sum_{i^-} k'_{i^-} C_{i^-}} \quad (5)$$

$$= \frac{RT}{F} \ln \frac{\sum_{i^+} k'_{i^+} C_{i^+} + \sum_{i^-} k_{i^-} C_{i^-}}{\sum_{i^+} k'_{i^+} C_{i^+} + \sum_{i^-} k_{i^-} C_{i^-}}$$

When equation (1) is valid:

$$\frac{k_{m^+}}{k_{n^+}} = \frac{k'_{m^+}}{k'_{n^+}} = \frac{P_{m^+}}{P_{n^+}} \quad (6)$$

(all m and n)

$$\frac{k_{m^-}}{k'_{n^-}} = \frac{k'_{m^-}}{k_{n^-}} = \frac{P_{m^-}}{P_{n^-}}$$

Equation (6) yields an independent method in which the ratio of the permeabilities may be experimentally found. Thus, this ratio may be experimentally tested for constancy as the concentrations and electric potential are altered.

It should be noted that if equations (2) and (3) are satisfied for any sub-group of ions in the system, then

equation (5), in which the summation is only over this sub-group, will apply. Thus, for example, for sheep erythrocytes there is a one-to-one exchange of sodium for potassium ions through the active transport system⁴. When there is no net movement of sodium or potassium ions across the membrane, equation (3) will be satisfied for these ions. Hence, letting $\alpha = k_{Na^+}/k_{K^+}$:

$$V = \frac{RT}{F} \ln \frac{\alpha Na_{l^+} + K_{l^+}}{\alpha Na_{r^+} + K_{r^+}} \quad (7)$$

where l and r now stand for the outside and inside regions. Equation (7) has been discussed by A. Hodgkin⁵ under the assumption that the α equalled P_{Na^+}/P_{K^+} and was therefore a constant.

A New Anthelmintic for Canine Hookworm

AN earlier communication¹ reported the discovery of a new series of quaternary ammonium compounds possessing anthelmintic activity against a wide range of nematodes parasitic in the gastro-intestinal tract of mammals. The hydroxynaphthoate salt of one of these compounds (I; bephenium) has proved to be of considerable practical value in the treatment of hookworm and roundworm in man², and in the prevention and treatment of nematodiriasis and parasitic gastro-enteritis caused by other trichostrongylid nematodes of sheep^{3,4} and cattle^{5,6}. In addition, it has proved to be highly effective against hookworm in dogs⁷, with less effect against canine ascarids, but its introduction into veterinary usage has been severely hampered by its emetic properties in the dog (Rawes, D. A., and McIntyre, A., private communications).

We now report a related series of compounds (II; $R = 2$ -thienyl, $A = H, Me, F, Cl, Br$ or NO_2) which were all effective against our two original screening organisms, *Nippostrongylus muris* and *Nematospiroides dubius*. The related compounds (II; $R = 2$ -furyl) were also prepared and tested but were of much less interest.

One of these compounds (II; $A = H, R = 2$ -thienyl), also known as 611C55, has since been tested extensively in larger animals (as its *p*-chlorobenzene-

sulphonate). It has been shown to be highly effective against both natural and experimental infections of *Ancylostoma caninum* and *Uncinaria stenocephala* in the dog. Compared with bephenium hydroxynaphthoate, 611C55 was marginally more effective against these two hookworms but at effective therapeutic dose-levels was only minimally emetic. Further experiments against natural infections suggested that 611C55 was also more effective against *Toxocara canis* and *Toxascaris leonina*. In contrast, 611C55 was substantially less effective than bephenium against some of the gastro-intestinal trichostrongyles in sheep. All these observations are of particular interest in the species/structure/activity complex, since salts of bephenium and 611C55 were of equal activity against *N. muris* and *N. dubius*; of the two, 611C55 was more effective against *Ascaris lumbricoides in vitro* (L. G. Goodwin, private communication) but they had similar and rather low activities against *Aspiculuris tetraptera* and *Syphacia obvelata*.

In those countries where hookworm infection in the dog is widespread and presents serious problems, tetrachloroethylene is the drug used in standard treatment. While effective, it possesses serious toxic properties. The development of 611C55 as an anti-hookworm drug for the dog is of considerable interest since it combines high efficiency with only mild emetic properties in this vomit-prone animal. Clinical trials with 611C55 against human hookworm infections are planned.

Irreversible Elimination of Muscle Receptors

NERVOUS activity is closely related to, and dependent on, the afferent inflow from peripheral receptors. In order to study the effect of decreased afferent inflow on spinal synaptic functions many experimental models have been suggested and investigated, but all these are open to criticism. De-afferentation by section of the dorsal roots proximally to the ganglion leads to degeneration of the central stump and corresponding synaptic endings in the spinal cord, thus causing changes which are not directly associated with the elimination of afferent discharges from the periphery^{1,2}. Section of the dorsal roots distally

to the spinal ganglion³ has a similar disadvantage since it causes changes of the retrograde degeneration type in the spinal ganglion cells. Besides this, both these methods lead to the elimination of all modalities of sensitivity, so that they are not suitable for investigations requiring the selective elimination of muscle afferent inflow. Bremer⁴ attempted to eliminate muscle receptor discharges by novocain infiltration of the muscle; but this is not a reliable method, and besides it is not possible to maintain this for any period of time. Neither are experimental procedures, such as tenotomy⁵, as yet sufficiently analysed to vouchsafe a solution in this direction.

During the study of the morphogenetic influence of the nervous system on the differentiation of muscle spindles in the rat, it was found that spindles begin to develop shortly before birth and cannot be considered as differentiated until 14 days after birth^{5,6}. When the sciatic nerve is either sectioned or crushed at the beginning of their differentiation, at birth, for example, their development is arrested and spindles disintegrate within a few days. When re-innervation of the muscle occurs following crushing of the nerve, recovery of motor functions occurs within 14 days; but spindles which had disintegrated during the denervation period do not differentiate again. Even five months after crushing the nerve, the muscles studied contained on the average 0.5 spindles (Fig. 1); they were either completely devoid of spindles or contained an occasional single spindle small in size and atypical in structure (Fig. 2), whereas control muscles contained 32.3 spindles. The presence of atypical spindles can most probably

Fig. 1. Number of muscle spindles in normal (white column) and re-innervated (black column) extensor digitorum longus 5 months after crushing the sciatic nerve in new-born rats (arithmetical mean of six animals $\pm$ standard error)

Fig. 2. Cross-sections of a normal muscle spindle from control extensor digitorum longus (C) and an atypical spindle from a re-innervated muscle (R) 5 months after crushing the sciatic nerve at birth. Hematoxylin-eosin, $\times c. 133$. E, sections from the equatorial zone; P, sections from the polar zones of each spindle. The scales on each side indicate the length of spindles computed from serial sections.

be explained by the assumption that they are spindles which had not disintegrated completely during the denervation period, and that the remnants were then re-innervated by the regenerating nerve fibres. As yet, only muscle spindles have been studied quantitatively, but tendon organs seem to behave in a similar way.

Since normal differentiation of spindles is governed by afferent nerve fibres^{5,6}, it was of obvious interest to find out whether in these animals afferent fibres have actually regenerated. For this reason muscle nerves were studied in rats after bilateral anterior rhizotomy. It was found that even though the nerve fibre diameters were somewhat smaller than on the control side, yet there were as many as 75 per cent regenerated afferent nerve fibres on the re-innervated side. They branched and formed free endings in the re-innervated muscles.

Pertinent data have also been obtained concerning the extrafusal muscle-fibres in re-innervated muscles, which were found to be even somewhat larger in diameter than those of the control muscle⁷. These re-innervated muscles, however, lagged considerably behind control muscles so far as their weight was concerned (38 per cent). It can thus be expected that the number of muscle fibres in the re-innervated muscles is reduced and probably also the number of motor neurons innervating these muscles⁸. Nevertheless, the remaining motor neurons, judging by the recovery of the muscle fibre diameter, seem to be functionally efficient.

Muscles without spindles may, after further analysis, represent a suitable model for studying the elimination of muscle proprioception when the afferent endings deprived of special terminal structures are functionally inactive. If free endings are still found to react to muscle stretch, then differences in discharges from endings with and without specialized end-organs could be investigated. Even the study of single atypical spindles might be of considerable interest since morphological and physio-

logical properties of a single known receptor could be correlated using this approach.

Lucerne Saponin Fractionation and Bloat

EVIDENCE has recently been presented that bloat on red clover is due primarily to the formation of stable foams due mainly to the clover cytoplasmic protein¹. Even accepting this factor as an important one in the production of bloat on lucerne, variation in bloat potency of the herbage still cannot be accounted for in terms of protein differences¹. Of course, extensive work in the United States on experimental bloat produced by lucerne saponins² still has to be taken into account when bloat factors are considered.

Following the work of Shaw and Jackson³ at Purdue, we examined the response of rat diaphragm respiration to the isolated saponins of lucerne. So far we have not found qualitative differences between lucerne saponins isolated from bloat-producing and non-bloat-producing herbage on the basis of this test, but inhibition increases with the amount of saponin added. Since it is considered³ that inhibition, as measured by this *in vitro* test, differentiates between bloat-producing and non-bloat-producing herbage, quantitative levels of saponins in lucerne may be a factor; however, little seems to be known about the seasonal variation in lucerne saponin-levels.

Previously, little chemical difference had been found between bloat-producing and non-bloat-producing herbage. Dried lucerne samples (kindly supplied by Dr. J. M. A. Tilley of the Grassland Research Station, Hurley) from bloat-producing and non-bloat-producing stands with no detectable difference in protein-levels or cytoplasmic/chloroplastic protein ratios (Tilley, J. M. A., private communication) had their saponins extracted and isolated by the cholesterol procedure of Thompson *et al.*^{4,5}. The bulk triterpenoidal saponins were compared with those isolated from other lucerne, Aberystwyth⁵ and Beltsville⁴ (the latter kindly supplied by Dr. C. R. Thompson) by means of paper chromatography. One-dimensional ascending multiple development was used (ethyl acetate/acetic acid/water: 13/3/3 by 3; Whatman No. 3 MM; 15 hr.; 40 cm. run; 30° C.) and the saponins were detected by a modified Liebermann-Burchard reagent⁶. Ten (and possibly twelve) constituent saponins were revealed by the improved methods of saponin fractionation—six were previously thought to be present⁵.

Differences have been found in the saponin constituents with high R_F values between bloat- and non-bloat-producing lucerne. The bloat-producing

lucerne contains an extra saponin (in low concentration) with the highest R_F . The constituent saponin with the next highest R_F is probably more abundant in bloat-producing lucerne than in non-bloat-producing samples. The other, 'random', lucerne saponin samples appear to correspond to those from the non-bloat-producing lucerne.

One would conclude from this evidence that certain constituent saponins may be involved in the production of the complex condition known as bloat. As one would expect, herbage samples chosen at random are allied to the non-bloat producing samples.

The saponin differences could possibly explain the transient nature of bloat potency of herbage. Certain saponin constituents acting in conjunction with foam-producing agents could provide the necessary conditions for bloat production.

The history of bloat research should have taught us to view with suspicion any theory of single-factor causation of pasture bloat and it should also underline the need for a chemical and biochemical study of bloat which seriously entertains the possibility of a multi-factor causation. The trend appears to be in this direction¹.

Effect of Reserpine on Heart Mitochondria

RESERPINE has been shown to uncouple oxidative phosphorylation of brain and liver mitochondria *in vitro*^{1,2}. In view of this, the effect of reserpine on heart mitochondria, *in vivo* and *in vitro*, and on the content of energy-rich phosphate compounds in heart muscle was studied.

Cats and guinea pigs were used. The experimental and control animals were injected intraperitoneally with 5 mgm./kgm. of reserpine in an average of 1.2 ml. of vehicle or with an equivalent volume of vehicle only, respectively. Twenty-four hours afterwards, the animals' chests were opened under artificial respiration. An 18-gauge hypodermic needle was inserted into the left ventricular cavity and coupled to a Sanborn Twin-Viso recorder through a Statham pressure transducer for recording intraventricular pressure. After the recording, a sample of tissue was excised from the left ventricle and quickly plunged into liquid nitrogen. These frozen tissue samples

were saved for the analysis of catecholamine and energy-rich phosphate compounds. The right and left ventricles were then excised and homogenized for isolation of the mitochondria. The phosphorus: oxygen ratios and response to the addition of phosphate acceptor (hexokinase and glucose) of these mitochondria were studied by the methods utilized previously by Lee *et al.*³.

Epinephrine and norepinephrine in ventricles of three control cats as determined by a spectrophotofluorometric method⁴ averaged 0.18 and 1.48 μ gm./gm. of tissue respectively. Following the reserpine treatment, the catecholamine content in three cats was decreased to 1-5 per cent of that found in control animals, confirming the previous work⁵. A similar degree of depletion of the catecholamine content was also observed following the reserpine treatment of guinea pigs. In addition, left ventricular systolic pressure and heart-rates of reserpine-treated cats and guinea pigs were 25-36 per cent lower than those found in control animals. In the examination of oxidative phosphorylation, it was found that the phosphorus: oxygen ratios of mitochondria of reserpine-treated cats and guinea pigs were significantly depressed compared to the controls (Table 1). It is noteworthy that the Q_{O_2} of reserpine-treated mitochondria is somewhat higher than the control values. Since the Q_{O_2} response of mitochondria to the addition of phosphate acceptor was found to be dependent on the extent of coupling of oxidative phosphorylation^{3,6}, experiments were performed in which the oxygen consumption of mitochondria was measured before and after the addition of phosphate acceptor. The results are also shown in Table 1. It is apparent in cats that the Q_{O_2} of control mitochondria is markedly increased by the addition of phosphate acceptor, whereas the Q_{O_2} of mitochondria from reserpine-treated cats show only a small increase following the similar addition of phosphate acceptor. Similar results were obtained with guinea pig mitochondria. These results suggest that oxidative phosphorylation is uncoupled in heart mitochondria of reserpine-treated animals. In view of these observations, the effect of reserpine, added *in vitro*, on the phosphorus: oxygen ratio of heart mitochondria from normal cats was studied. In these experiments, reserpine (final concentration of 50 μ gm./ml.) or vehicle only was added to flasks containing normal mitochondria. It was found that phosphorus: oxygen ratios of normal mitochondria with and without reserpine were 2.40 ± 0.09 (S.E.) and 3.12 ± 0.08 (S.E.) respectively. These results suggest that reserpine uncouples oxidative phosphorylation in cat heart mitochondria both *in vitro* and *in vivo*. In two experiments, in which reserpine was administered subcutaneously to guinea pigs in a dose of 0.03 mgm./kgm. daily for 15 days,

Table 1. THE EFFECT OF PRE-TREATMENT OF ANIMALS WITH RESERPINE ON PHOSPHORUS: OXYGEN RATIO AND ACCEPTOR RESPONSE OF HEART MITOCHONDRIA

Guinea pig experiments			
Type	No. of exp.	P:O ratio $\pm$ S.E.	$Q_{O_2} \pm$ S.E. μ atom/mgm. protein/hr.
Control	17	3.11 ± 0.08	8.17 ± 1.08
Reserpine	10	2.39 ± 0.05	12.54 ± 0.71
Cat experiments			
Type	No. of exp.	P:O ratio	Q_{O_2}
Control	16	3.25 ± 0.08	9.43 ± 0.4
Reserpine	9	2.34 ± 0.20	11.89 ± 0.50
Q_{O_2} without acceptor			
Control	5	2.54 ± 0.5	8.16 ± 1.0
Reserpine	5	6.78 ± 2.1	8.80 ± 2.9
Q_{O_2} with acceptor			

heart mitochondria from these animals showed a similar uncoupling of oxidative phosphorylation. However, due to a limited number of experiments no definite conclusion can be drawn at present.

In view of the above results, the contents of adenosine triphosphate, phosphocreatine and inorganic phosphate of heart muscle in control and reserpinized cats were studied according to the methods of Furchgott and deGubareff^{7,8}. Although the uncoupling of oxidative phosphorylation in mitochondria might be expected to result in a lower level of energy-rich phosphate compounds, the results in Table 2 show that contents of these compounds in hearts of reserpinized animals are unchanged when compared to control values. No satisfactory explanation is at present available for this phenomenon. Two possibilities may be considered. First, the *in vivo* uncoupling effect of reserpine may not be pronounced enough to impair the synthesis of high-energy phosphate compounds. Secondly, if the synthesis of these compounds is assumed to be impaired, this impairment of synthesis may be compensated by the depressed utilization of them by heart muscle. It has been shown in the dog heart-lung preparation⁹ that increasing the resistance against which the heart must work resulted in a decrease in the high-energy phosphate content of the left ventricle. Therefore, the lower ventricular pressure and lower heart-rate of reserpinized cats, resulting in less ventricular work compared to those of control, may compensate, at least partially, for the decreased synthesis of high-energy phosphate compounds in reserpinized animals, thus maintaining the control-level of these compounds.

Table 2. EFFECT OF RESERPINIZATION ON THE CONTENT OF ATP, PC AND IP IN HEART MUSCLE OF CATS

Type	No. of exp.	IP $\pm$ S.E.	PC $\pm$ S.E.	ATP $\pm$ S.E.
Control	4	2.52 $\pm$ 0.08	8.48 $\pm$ 0.27	5.47 $\pm$ 0.18
Reserpine	5	3.83 $\pm$ 0.57	9.61 $\pm$ 1.0	5.34 $\pm$ 0.25

All values are expressed in μ mole/gm. wet weight tissue. ATP, Adenosine triphosphate; IP, inorganic phosphate; PC, phosphocreatine.

We acknowledge with thanks the assistance of Dr. S. M. Kirpekar for analysis of catecholamines. We also wish to thank Dr. A. J. Plummer of Ciba Pharmaceutical Products, Inc., for supplies of reserpine and vehicle.

This work was supported by a grant (No. H-2875) from the National Institutes of Health, U.S. Public Health Service.

HÆMATOLOGY

Identity of Hæmoglobin A₂

At least two forms of adult hæmoglobin are present in the blood of the normal human adult, a main component hæmoglobin A₁ and a minor one hæmoglobin A₂ (ref. 1). In normal individuals the concentration of hæmoglobin A₂ is about 2.5 per cent of the total hæmoglobin. In persons heterozygous for the Cooley gene, this amount is increased to a level of about 5 per cent. The A₂ fraction can be isolated from the main component by starch-block electrophoresis and by chromatography on carboxymethyl cellulose². The presence of two hæmoglobin A₂ fractions in some persons, belonging to different generations of one family, makes it likely that the synthesis of hæmoglobin A₂ is genetically determined³. This led us to investigate whether there exist chemical differences between the main component, hæmoglobin A₁ and hæmoglobin A₂, and to locate eventual differences.

We started with hæmoglobin A₂ prepared from erythrocytes of a person with thalassaemia minor, because of the higher hæmoglobin A₂ concentration in the blood of carriers of the Cooley gene. In a later stage of the investigation also the hæmoglobin A₂ of a normal person was investigated since the possibility of differences between these A₂ hæmoglobins could not be excluded.

The A₂ component was isolated and purified by chromatography on carboxymethyl cellulose using a pH gradient². After tryptic digestion at pH 8.0 in a pH-stat of the heat-denatured protein, those peptides that are soluble at pH 6.5 were 'fingerprinted'⁴. The resulting pattern showed differences in peptides numbered 26, 12 and 16 from the pattern of normal adult hæmoglobin⁵. By specific staining reactions for arginine and tyrosine an additional difference in the unresolved part of the neutral band of the 'fingerprint' could be visualized. The remaining part of the 'fingerprint' was identical for hæmoglobin A₂ and hæmoglobin A₁.

The differences in spots 26 and 12 indicate that the differences are located in the β -chain; these peptides only being present in this chain. This, however, could not be said for peptide 16 and the difference in the neutral band, as it is known that these spots contain peptides which occur in both chains. In order to learn whether these differences are localized in the α - or β -chain, 100 mgm. of globin of hæmoglobin A₂ was prepared with the use of the method of Anson and Mirsky⁶. The globin was separated into two fractions, one consisting of the α -, the other of β -chains, by chromatography on 'Amberlite IRC 50', using a urea gradient⁷. 'Fingerprints' of the first fractions of hæmoglobin A₁ and hæmoglobin A₂ consisting of α -chains appeared to be identical when stained with ninhydrin as well as when stained with special reagents on arginine-, histidine-, tyrosine-, tryptophan- and sulphur-containing peptides.

All the differences mentioned above, however, could be visualized in the 'fingerprints' of the β -chains (Fig. 1). With the 'fingerprinting' method no differences could be detected between the hæmoglobin A₂ of a normal individual and the hæmoglobin A₂ of a carrier of the Cooley gene.

These results indicate that hæmoglobin A₂, like foetal hæmoglobin, differs from adult hæmoglobin in the β -chains and can be denoted by $\alpha_2\delta_2$. The differ-

Fig. 1. Comparison of the β -chains of haemoglobin A_1 and A_2 . A, Arginine; H, histidine; S, sulphur; Tr, tryptophan; and Ty, tyrosine-containing peptides

ences between the β -chain of haemoglobin A_1 and haemoglobin A_2 are, however, smaller than those between the β -chain of haemoglobin A_1 and that of foetal haemoglobin.

We may conclude that in the human erythrocytes three haemoglobins are present, all three with the same α -chains, but with β -chains that differ in several parts.

These investigations were supported by a grant of the Dutch Organisation for Pure Research (Z.W.O.).

The Half-life of Human Platelet Phosphatide

PLATELET life-span has been measured by incorporating into the platelet a tracer compound and following its disappearance. The labels used have included radioactive phosphorus, as ^{32}P -orthophosphate and as ^{32}P -diisopropyl fluorophosphonate, radioactive chromium, radioactive sulphur and radioactive carbon. Aas and Gardner¹ reported a life-span of 9–11 days using *in vitro* labelling with chromium-51. Leeksa and Cohen² calculated a life-span of 8–9 days using ^{32}P -diisopropyl fluorophosphonate *in vivo*. Both methods gave a calculated life-span that was longer than previous results had suggested and longer than the 1½–3 day half-life for transfused ^{32}P -platelets reported by Adelson *et al.*³ These authors pointed out the hazards of using *in vitro* techniques and attempted to reduce platelet handling to a minimum. A longer platelet life-span would explain more adequately the occurrence of a maximum depression of platelets at 25–30 days in human beings exposed to radiation⁴.

Following the use of therapeutic doses of phosphorus-32 we have found radioactivity in isolated platelet phosphatides three and four weeks following injection. Platelets were obtained by differential centrifugation, using ethylenediamine tetraacetic acid as the anticoagulant. Smears revealed little or no contamination with white blood cells. The phosphatides were isolated using the Folch extraction procedure⁵ and ascending chromatography on glass fibre impregnated with silicic acid⁶. The lipid spots were identified with rhodamine 6G and ultra-violet fluorescence; these spots were cut out, and their radioactivity was measured using a thin-window Geiger tube. Phosphorus was determined by the Gomori method⁷.

Analyses were performed simultaneously on platelets and 'platelet poor' plasma samples (centrifuged at approximately 1,000g).

Table 1 presents the comparative results for platelets and plasma. It is evident that considerable radioactivity was present in platelets at the end of 21 days, and significant radioactivity was found at 28 days in patients Aregi and Whitehead (13 and 10 actual c./min. above background were found respectively, using 1,000 counts, with a background activity of 17 c./min.). Activities of similar magnitudes were found in the phosphatidyl choline of both platelets and plasma. However, platelets consistently yielded significant amounts of phosphatidyl ethanolamine whereas only small amounts were found in plasma and not in every patient. This was also demonstrated in radioautograms of the chromatograms.

The specific activities found are consistent with an exponential curve of disappearance, with a suggestive half-life of 10–13 days for platelet phosphatidyl choline. It should be emphasized that this is a figure for the phosphatide and not whole platelets. The data are not yet adequate to determine if there is a

levelling off to a relatively constant level of activity.

Our observations are compatible with the hypothesis that human platelet life-span is longer than present data in the literature suggest. It is likely that a combined megakaryocyte-platelet phosphatide half-life is being measured. The megakaryocyte probably incorporates the ^{32}P -orthophosphate into the phosphatides and on 'maturation' delivers the labelled platelets into the peripheral circulation. The time of this process is unknown in humans, although the fact that the peak of platelet radioactivity in humans is usually found one week after injection of ^{32}P -orthophosphate may suggest 7 days. Kinoshita⁸ has reported a 5-day period for the development of the mature megakaryocyte and release of the platelets by time-lapse photography of rabbit marrow.

The questions of adsorption of phosphatides from plasma, a more active process of exchange with plasma phosphatides, and that of possible phosphatide metabolism of platelets remain to be evaluated. The appearance of (^{14}C) acetate-labelled phosphatides in human red blood cells following *in vitro* incubation with labelled plasma was recently reported by Lovelock *et al.*⁹.

The fact that labelled phosphatidyl ethanolamine is consistently found in platelets while little or no phosphatidyl ethanolamine is found in our plasma samples argues against simple adsorption from plasma. Indeed, the reverse has been postulated, namely, that plasma phosphatidyl ethanolamine may be derived in part from ruptured platelets¹⁰. Our results are compatible with this concept.

The half-life of plasma phosphatidyl choline varied from approximately 9 to 27 days, using a semi-logarithmic plot of the specific activities. This too is considerably longer than present turnover data in the literature indicates^{11,12}. This will be discussed in more detail in a subsequent report.

Further work is in progress.

RADIOBIOLOGY

Incorporation of Cesium-137 from Nuclear Debris into the Biosphere

It is generally assumed that caesium deposited on plant leaves or stems can be taken up by the plant¹⁻⁵. When such plants are ingested by a cow a considerable part of the ingested caesium is excreted in the milk. The results of the experiments described here, however, seem to indicate that caesium-137 can follow an alternative route from fall-out to man that under certain conditions could well be responsible for part of the caesium-137 found in milk and meat.

In order to obtain data concerning the transport of caesium in soil, experiments have been carried out with artificially contaminated soils. When caesium is present at the top of a compact layer of clay it can scarcely be washed downwards by water free of electrolytes (Fig. 1). However, in a layer of crumbled clay or loosened sand a considerable transport of caesium by water was observed. This transport is apparently caused by the downward movement of very small particles containing most of the caesium. From sedimentation experiments, it became apparent that about 50 per cent of caesium-137 present in a slightly alkaline clay (pH 7.5) was adsorbed on to particles smaller than 2μ , representing only 5 per cent of the total mass of the clay. In a sand free of humus (pH 7.2) more than 70 per cent of the caesium-137 was found on only 2 per cent of the total mass. These small soil particles washed downwards with rain-water were retained by a compact layer of clay in a model experiment, causing a maximum activity at the top of the compact layer (Fig. 2). The relatively large activity at the bottom of a furrow described by Herbst⁶ could be caused by a retention of small particles carrying a large fraction of the caesium-137 by the compact layer of clay just under the ploughed layer.

Fig. 1. Distribution of radiocesium, after surface contamination with $0.10 \mu\text{c./cm.}^2$, in compact clay after 700 mm. water precipitation (500 mm. with a drop-diameter of 0.2 mm. and 200 mm. with a drop-diameter of 6 mm.)

Fig. 2. The distribution of radiocesium in clay after 1,000 mm. precipitation. The layer from 0-5 cm. depth is crumbled clay, from 5-12 cm. depth the clay is compact

When 1-gm. samples of a clay and a sand containing 0.1 µc. caesium-137 per gm. soil were shaken for 4 hr. with 2.5 ml. acetate buffer (pH 4.8) only 2 and 5 per cent respectively of the caesium-137 went in solution. This result might point to a small assimilation by the roots of plants. Indoor experiments on grass, growing on clay or sand containing 10 µc. caesium-137/kgm., showed (in agreement with the results of Romney *et al.*⁷ and Nishita *et al.*⁸) that only a few tenths of 1 per cent were actually assimilated in a period of several months. Probably only the exchangeable fraction of the caesium-137 present in the near vicinity of the roots was assimilated.

The assumption that the main route of contamination of the biosphere is by foliar absorption was re-examined in experiments with cut grass. Thoroughly washed grass was held for 15 min. in solutions with caesium-137 in different concentrations. The results of measurements of the amount of absorbed caesium-137 indicate that from extremely

Fig. 3. The fraction of caesium-137 coming off suspended clay after shaking for different lengths of time with solutions of varying pH . +, After 5 min.; o, after 30 min.; ●, after 240 min.

diluted solutions of caesium-137 in water about 30 per cent is fixed by the leaves in 15 min. Since even washed grass still contains about 0.1 per cent (weight) of adhering soil particles a considerable part of the absorbed caesium-137 might actually be bound to these particles. Natural grass contains 0.2-2 per cent silica originating from adhering soil⁹.

Cows may ingest together with grass several hundred grams of top soil a day (private communication by staff members of the University Veterinary X-ray Department). In Fig. 3 it is shown that with decreasing pH increasing amounts of caesium-137 go in solution. In the omasum of the cow a pH of 2-3 prevails, and this is sufficient to dissolve in $\frac{1}{2}$ hr. about 20 per cent of the caesium-137. Under suitable conditions, for example, prolonged drought or low caesium-137 activity of rain-water, soil could become of importance as a source of caesium-137 to the cow and possibly also to pigs and goats. It might be worth while to re-investigate available data for an evaluation of the relative importance of soil in the transport of caesium-137.

In vitro Uptake of Iodine-131 by Salivary Glands, Stomach and Placenta

THE ability of the thyroid gland to accumulate iodide against a concentration gradient and to maintain a high gland/plasma concentration is well known. Recently it has been shown that *in vitro* uptake of iodine-131 by the lactating mammary tissue of the rat was 10-15 times that of liver, muscle or boiled mammary tissue, and uptake of iodine-131 was increased to about twice the level observed in fresh mammary tissue by storage for 24 hr. in Ringer-phosphate at 7° C. and continued high for 25 days storage¹. In the present experiments, *in vitro* uptake of iodine-131 by salivary glands, that is, submaxillary, parotid and sublingual; different regions of stomach, that is, fundic and pyloric; placenta, that is, foetal and maternal; duodenum and liver of rat were studied by incubating the tissue at 37° C. for 6 hr. in nutrient medium with pH 7.2 and the effects of thiouracil, potassium thiocyanate, sodium cyanide, iodide and thyroid-stimulating hormone on uptake of iodine-131 by these tissues were also investigated.

The T/M value (counts per minute per 100 mgm. tissue divided by counts per min. per 0.1 ml. medium) for uptake of iodine-131 by parotid gland was significantly higher when compared with that of submaxillary or sublingual glands. Slices from the fundic

region of the stomach showed significantly higher T/M value for uptake of iodine-131 when compared with slices from the pyloric region. The difference between the T/M values for uptake of iodine-131 by slices from foetal and maternal placenta was not significant. Slices of liver showed very low uptake of iodine-131 and the T/M values for the fresh and boiled tissues were practically the same. Addition of thiouracil (0.02 mgm./ml.) to the medium resulted in a decrease in uptake of iodine-131 by salivary glands and stomach slices, but it had no effect on uptake of iodine-131 by placenta or liver. Potassium thiocyanate and sodium cyanide also caused a decrease in uptake of iodine-131 by salivary glands and stomach, but not in the case of placenta or liver. Addition of thyroid-stimulating hormone (50-200 mgm./ml.) to the medium containing tissue slices did not show any effect on uptake of iodine-131 by these tissues.

Addition of large doses of penicillin (1,000 i.u./ml.) to the medium resulted in a decrease in T/M values for uptake of iodine-131 by salivary glands and stomach slices. The results for T/M values for uptake of iodine-131 by salivary glands and stomach of mouse, dog and cow were similar to that for rat except the difference between parotid and submaxillary glands was not so marked as in the case of rat. Uptake of iodine-131 by placenta of mouse was similar to that of rat. In general, the results indicate that iodide concentration mechanism in the salivary glands and stomach, but not in liver or placenta, appears to be similar to that of thyroid gland.

Tumours of the Small Intestine in Rats after Intestinal X-Irradiation

CERTAIN effects of X-irradiation of the exteriorized or *in situ* intestine of Sprague-Dawley rats were previously reported from these Laboratories¹. In view of the scarcity of information concerning the occurrence of tumours after exposure of the intestine to irradiation, survivors of that study, and their controls were kept for further observation. This communication reports the incidence of intestinal tumours among 51 rats that were irradiated at an age of 5 months and were killed between 9 and 30 months later. All but seven experimental and two control animals were killed because of the presence of tumours or other diseases. The nine rats were arbitrarily killed at an age of ten months at the conclusion of the period of experimentation.

In the exposures of the exteriorized intestine, the entire intestine except a portion of the duodenum and the rectum was delivered through an incision in the abdominal wall for irradiation while the remainder of the body was protected by a lead shield. The partial-body exposures were carried out through a window in a lead shield designed so that only the abdominal region was exposed. The LD_{50} was about 1,550 r. and the LD_{90} about 1,900 r. for both modes of exposure.

The incidence of intestinal tumours in irradiated and control groups is presented in Table 1. There the animals are grouped by exposure into doses

Table 1. INCIDENCE OF INTESTINAL TUMOURS

Method of exposure	Dose range (r.)	Incidence	Type of tumour
Exteriorized	900-1,300 1,500-1,900	0 of 10 5 of 18	3 mucinous carcinomas 1 leiomyosarcoma 1 lymphosarcoma
Partial body	700-1,300 1,500-1,900	0 of 11 2 of 12	1 mucinous carcinoma 1 leiomyosarcoma
Control		0 of 25	

below the LD_{50} and those at or above the LD_{50} . The number of survivors at high levels was necessarily small. All intestinal tumours occurred in the small intestine, the region of principal histological damage. The earliest tumour was observed at 9.5 months.

The incidence of malignant intestinal tumours is lower and the tumour development later than that reported by Osborne². However, the radiation exposures cited here were predominantly in the mid-lethal range in contrast to the uniformly lethal dose-range employed by Osborne, who obtained survival by clamping the superior mesenteric artery and vein during exposure. Tumour development in this experiment was confined to the mid-lethal and higher dose-range, for which substantial acute intestinal damage was previously demonstrated histologically¹. The results presented here are compatible with a dose-dependent carcinogenic effect of X-irradiation on the small intestine of the rat.

We gratefully acknowledge the technical assistance of Alma L. Crosby and Glenda S. Vogt.

BIOLOGY

Fine Structure of the Neurosecretory System in Lepidoptera

THE following is a short account of an electron microscope study of neurosecretory cells found in three lepidopterous insects, *Bombyx mori*, *Philosamia cynthia ricini* and *Papilio xuthus*. I believe I may have succeeded in observing early stages in the formation of secretory granules in the perikarya of neurosecretory cells of the intercerebralis.

The brain-cardiaca-allata complexes were taken from mature larvae and fixed in 1 per cent osmium tetroxide adjusted with phosphate buffer to pH 7.0-7.4. The tissue was then embedded in methyl methacrylate and *n*-butyl methacrylate in the proportions 1:3.

Mitochondria, Golgi apparatus and the endoplasmic reticulum are commonly present as in neurones in general. The most striking feature frequently encountered is the appearance of fine, elliptical, electron-dense granules (Fig. 1, *g*). These

Fig. 1. Elemental granule (g), near Golgi apparatus (G) in the neurosecretory cells of intercerebralis (*Philosamia*). Note the mitochondria (m). Electron micrograph. ($\times 44,160$)

granules are relatively uniform in size, each being 900–2800 Å. (1500 Å. on average) across their longest axis. These granules may be equivalent to the elemental granules^{1–3} described in the neurosecretory system of vertebrates. They are either neurosecretory material or a substance intimately associated with it. They appear in crowds in the peripheral part of the cell and some are aggregated into giant granules. It is highly probable that the giant granules coincide with the secretory granules of high refractive index seen under the light microscope.

Those cells which possess few of these granules usually contain in their place many well-defined membranes of the endoplasmic reticulum. Since the secretory granules are frequently encountered within the Golgi zone, it seems possible that granule-formation occurs in close relation to the Golgi apparatus (G). Moreover, as shown in Fig. 1, the mitochondria which occur near the Golgi apparatus are constricted in such a way as to form strings of elliptical-shaped bodies (m). The cristae in these bodies are more numerous than in the mitochondria seen in other parts of the cell. Some distance away from the Golgi apparatus the mitochondria appear to fragment and their parts (that is, the elliptical-shaped bodies) become scattered among the electron-dense granules already referred to. Gradations can be seen between the elliptical-shaped bodies and the more dense bodies which lack cristae. These observations seem to favour the view that the elemental granules may originate from mitochondria which receive some material from the Golgi zone, as has been suggested for zymogen granules of the mouse pancreas⁴. The elemental granules in the perikarya of neurosecretory cells of the intercerebralis are transferred via axons into cardiaca and allata.

Day-Length as a Factor affecting the Variation of *Chenopodium* spp. in Britain

CUMMING¹ has recently reported from the genus *Chenopodium* the existence of precociously reproductive individuals induced by short photoperiods. This communication is concerned with similar observations made during 1955 and 1956 on *Ch. album* L. and *Ch. polyspermum* L. These results were obtained during an experimental investigation into the variation pattern and cytotoxonomy of *Chenopodium* in Britain, further details of which are being published elsewhere.

Previously, Khlebnikova², Potapenko³, Fuller⁴ and Wahl⁵ had shown that many species of the genus *Chenopodium* were photoperiodically short-day with or without a critical day-length. In addition, Wahl suggested that the day-length factor may be of significance in experimental taxonomy when he showed that the form of the mature phenotype in *Ch. bushianum* Aell. and *Ch. missouriense* Aell., in the United States, depended on the average day-length a plant received during maturation, and hence on its date of germination.

Independently, I had observed a similar, though more complex, situation in Britain. Both *Ch. album* and *Ch. polyspermum* are similar in possessing parallel intraspecific variation patterns. This intraspecific polymorphism involves a range of biotypes which form at one extreme of the continuum individuals which are predominantly vegetative with 'spicate' inflorescences, while at the other extreme plants are largely reproductive with 'cymose' inflorescences. The morphological extremes of this continuum have in the past been given taxonomic status of one form or another^{6–10}. Some of these taxa are shown in Table 1.

Table 1	
Inflorescence largely spicate	Inflorescence largely cymose
<i>Ch. album</i> : f. <i>spicatum</i> (Koch) Aellen	f. <i>cymigerum</i> (Koch) Aellen
v. <i>candicans</i> (Lam.) Syme	v. <i>viride auct.</i> (non L.)
v. <i>incanum</i> Moq.-Tand.	v. <i>concatenatum</i> Moq.-Tand.
<i>Ch. polyspermum</i> v. <i>acutifolium</i> (Sm.) Gaud.	v. <i>obtusifolium</i> Gaud.

Both genetic and environmental variables (for example, temperature and day-length) are now known to be responsible for this polymorphism, and experiments under glass and in the field have elucidated some of the problems involved. It has been found, for example, that nearly all spicate biotypes of *Ch. album*, germinating in the field in southern England after the beginning of August (day-length about 15 hr. and decreasing), produce markedly cymose phenotypes which exactly phenocopy those biotypes which are less flexible and remain cymose under all conditions. Similarly, if seed from *Ch. polyspermum* v. *acutifolium*, which normally develops a vegetative, spicate phenotype when germinating in the spring, commences growth in the open after the third week in July (day-length about 15½ hr. and decreasing) it will mature into the cymose type, which is usually described as v. *obtusifolium*.

Fig. 1 shows a plastocline of *Ch. polyspermum*. This plastocline was produced experimentally by planting this species in a heated greenhouse (c. 25°C.) at intervals of three weeks during the spring and early summer of 1956. Thus the various treatments comprised differing and increasing day-lengths. As illustrated, the form of the inflorescence and the leaf-shape progressively change as the length of day increases. Those plants receiving an average day-

Fig. 1. A day-length plastocline of *Ch. polyspermum* L. (P1-P6 v. *obtusifolium* Gaud.; P7-P10 v. *acutifolium* (Sm.) Gaud. The day-lengths given below represent the average photoperiod (in hr.) received by each treatment: P1, 11·00; P2, 11·35; P3, 12·00; P5, 13·10; P6, 14·25; P7, 14·50; P8, 15·17; P9, 15·27; P10, 16·00

length (as calculated from germination to visible inflorescence initiation) of less than 13½ hr. at 25° C. were more or less exact phenocopies of *Ch. polyspermum* v. *obtusifolium*. As the day-length increased so the plants became more vegetative, their leaves more acute, and the inflorescences less cymose until, in average day-lengths exceeding 15½ hr., the treated plants became indistinguishable from v. *acutifolium*. A similar day-length plastocline of *Ch. album* was not obtained under the same conditions since the high temperature prevented normal growth in this species. However, a comparable plastocline was obtained by planting *Ch. album* in the open at monthly intervals from July until October.

While cymose individuals of *Ch. album*, which owe their predominantly reproductive habit to naturally occurring short-days (short-day plastodemes) and not to the inflexible expression of their genotypes (cymose genodemes), are reasonably widespread in Nature after the middle of August, at least in southern England, similarly naturally occurring populations of *Ch. polyspermum* have been observed in Britain only where this plant occurs as a greenhouse weed and never, as yet, in the open. This observed absence of short-day, cymose, plastodemes of *Ch. polyspermum* in the open is almost certainly due to the higher temperature requirements of this species, which occurs as a native only in southern England and finds its greatest development in warmer areas. Where short-day cymose phenocopies were produced experimentally, in the field in this species, full inflorescence elaboration was not completed owing to the prevailing low temperatures in October. In warmer climates, however, particularly in southern Europe and parts of the United States, the interaction of day-length and biotype and the resultant phenotypic distributions should prove worthy of further study.

In conclusion, attention is directed to the heterogeneous reaction of the spicate genodemes of *Ch. album* to autumnal short-days, in that not all the spicate biotypes do become cymose. In view of this, and in view of the phenocopying phenomena, it is conceivable that the origin of the inflexible cymose genodeme can be explained in terms of Waddington's "genetic assimilation"¹¹. It is hoped that further experiments planned will add to our knowledge of this process in plants.

Most of the experimental results were obtained at the University of Southampton during the tenure of a Department of Scientific and Industrial Research maintenance award.

Lepidoteuthis grimaldii—a Squid with Scales

In August 1959, I collected the stomach contents of a sperm whale caught off Madeira and flensed at the whaling station at Canical in Madeira. These included three heads and four mantles of squids belonging to the genus *Lepidoteuthis*. The squids of the only known species in the genus are characterized by having a covering of 'scales' on the mantle. Joubin in 1895 first noted this unusual feature in his description of *Lepidoteuthis grimaldii* Joubin. The description was based on two mantles from a sperm whale's stomach and a fragment from the stomach of a Risso's dolphin (*Grampus griseus*). These animals were caught off the Azores. Lönnberg¹ regarded Joubin's description of scales with some scepticism, and considered that the structures referred to were the same as those he had described as papillae in *Moroteuthis ingens* (E. A. Smith, 1891). Later, Joubin² gave a more detailed description of the material in his possession. No further records of this species were made until Rees and Maul³ noted it in the fauna of Madeira. Mr. G. E. Maul, of Funchal Museum, saw two specimens of this species in the stomach contents of sperm whales caught off Madeira

Table 1. MEASUREMENTS IN CM.

	Present specimens				Joubin's specimens	
Dorsal mantle, length	88.6	69.0	75.3	62.0	86.0 (total length)	72.0
Ventral mantle, length	83.6	64.7	70.4	57.8		
Maximum mantle width	24.1	19.7	19.5	21.5	25.0	24.0
Fin, length	38.0	33.0	32.0	28.0	42.0	32.0
Fin, width	40.5	28.2	26.5	23.4	40.0	36.0
'Tail' behind fins	5.0	5.0	6.0	5.0		
End of pen projecting beyond body	1.8	3.0	4.2	3.3		
Maximum width of scales	1.0	0.9	0.8	0.8		

and one which was vomited by another whale killed in the same locality between 1952 and 1954⁴. He was also able to collect a complete specimen. Dr. R. Clarke⁵ saw the mantle of a specimen, again in the stomach of a sperm whale caught off the Azores and processed at San Miguel.

Thus, the present record is the fourth published and only the second to include the head, which has not yet been described.

The 'scales' of these specimens are rather softer than those usually forming the external protection of fish, although, as suggested by Joubin in 1895, they resemble ganoid scales in general appearance. It is perhaps pertinent to mention that they seem to have become rather softer since being preserved in formalin, and my recollection of the fresh condition is of rather 'horny' structures. Those on the posterior of the mantle lie side by side but there is some overlapping in the anterior (oral) region of the mantle.

There is no reason for supposing that these newly found specimens belong to a different species from that described by Joubin.

With regard to the past controversy over the use of the word 'scales' when referring to the structures in *Lepidoteuthis*, I have examined the papillae of

Moroteuthis ingens (Smith, 1891) in several specimens collected from the stomachs of sperm whales and in their general appearance they are quite different from the 'scales' in these *Lepidoteuthis* specimens.

According to the Concise Oxford Dictionary the term 'scale' includes "plate of thin outer piece with some resemblance to fish scale in organic or other object" as well as the narrower meaning of "one of the thin horny overlapping plates protecting the skin of many fishes and reptiles". Thus, the term covers the condition found in *Lepidoteuthis*, but seems inapplicable to that found in *Moroteuthis*.

d'Orbigny⁶ described the mantle of *Onychoteuthis dussumieri* d'Orbigny 1839 as being "finement chagrinee". This was discussed by Adam⁶ and sounds rather similar to the 'papillae' described by him in *Pholidoteuthis boschmai* Adam, 1950, and to the "scale like plates" described by Voss⁷ in *Pholidoteuthis adami* Voss, 1956.

Fig. 2. Close up of 'scales' of *Lepidoteuthis grimaldii* Joubin 1895. Scale in cm.

Fig. 1. Ventral view of mantle of *Lepidoteuthis grimaldii* Joubin 1895

These structures seem quite similar to those found in *Lepidoteuthis*, but are only about one-tenth of the size.

Voss⁸ also described *Thysanoteuthis rhombus* as being 'scaled', but he adopted the term from previous literature (notably d'Orbigny⁶) which seems to be misleading. Specimens of this species in the *Discovery* Collections have no sign of structures which could be described as 'scales'.

A study of the relationships of *Lepidoteuthis* should prove of great interest, and a full description of the squid will shortly be published in conjunction with Mr. Maul.

I am indebted to Mr. A. Madgwick for the photographs.

Origin of Angiosperms

PROF. T. M. HARRIS, in his recent presidential address to Section K (Botany) of the British Association¹, has directed attention to the successive failure of attempts to find fossils which appear to be ancestors of the Angiosperms. He makes a plea for more intensive study of Angiosperm-like fossils from rocks of the Triassic, Jurassic and Lower Cretaceous periods, in the confident hope that some will be found to be the early Angiosperms that have eluded search for so long. I suggest that this search for the fore-runners of the Angiosperms might more profitably be directed towards gymnospermous plants occurring in the Middle Cretaceous period immediately before the first appearance of Angiosperms. In my opinion the origin of Angiosperms may have been so sudden and their early evolutionary change so rapid that there is little likelihood of early Angiosperms having been preserved as fossils.

Ten years ago I suggested² that the origin of the Angiosperms could be related to the occurrence of multiple-allele incompatibility between the pollen and diploid tissue surrounding the ovules. Recently, this hypothesis has received striking support from the work of Lewis and Crowe³, who have made reciprocal crosses between self-compatible and self-incompatible species, and have shown, not only that the multiple-allele incompatibility in various Angiosperm families is of ancient origin within those families, but also that in the Solanaceae and Scrophulariaceae the incompatibility must have arisen before these families diverged from one another. In view of these findings, I believe that the abrupt origin of angiospermy, following on the evolution of this type of incompatibility, is a very real possibility. The sudden appearance of Angiosperms in the fossil record at a time when "no other stirring event occurred in the world", to quote Prof. Harris¹, would then be explained.

If this hypothesis is correct, it would follow that the Angiosperms originated immediately prior to their appearance in the fossil record, and that they arose from a single species in which this incompatibility had developed. Moreover, the change from gymnospermy to angiospermy would probably have been abrupt. Prior to the evolution of incompatibility, mutations which prevented direct access of the pollen to the ovules would be disadvantageous, owing to the greater likelihood of failure of the pollen to bring about fertilization, and the lack of any compensating advantages. However, once multiple-allele incompatibility had appeared, such mutations would be strongly favoured, since self-pollen would thereby be excluded from fertilization, while all but a minute fraction of cross-pollen would not. It is unlikely that fossils exist of this particular species in which it is presumed that the incompatibility evolved and the transition to angiospermy occurred. Hence, transitional forms may never be found. However, the family or order of Gymnosperms containing this hypothetical species might well be represented among fossils from just before the rise of the Angiosperms. This family would presumably be expected to show some of the characteristics of Angiosperms, such as the peculiarities of stamen construction, but nevertheless be gymnospermous in reproduction. Thus, in my opinion, the best hope of finding recognizable ancestors of the Angiosperms lies in a study of fossil Gymnosperms in the Middle Cretaceous period,

just antecedent to the appearance of the Angiosperms.

Nature of the Resistance of Oat Varieties to Races of Oat Stem Rust

WHETHER resistance of a given variety of plant to a given race of rust is based on a nutritional mechanism or on an inhibitory one seems still to be a debatable point. For example, is resistance due (a) to the inability of the rust fungus to obtain from the resistant host all the chemical precursors necessary for adequate nutrition, or is resistance due (b) to the presence of substances in and natural to the host or of substances arising from the interaction of the host and pathogen that directly or indirectly result in the inhibition of the pathogen? The observations recorded here contribute somewhat to the elucidation of the mechanism of resistance.

In the following experiments, the plant host comprises varieties of oats (*Avena sativa* L.) and the pathogen races of oat stem rust (*Puccinia graminis* Pers. f.sp. *avenae* Erikss. and Henn.). The 'leaf sandwich' technique designed and used in this work was a modification of a 'tissue transplant' technique described by Sharp and Emge¹.

The sandwiches were of three types: (a) a leaf from each of two susceptible (S) plants; (b) a leaf from a susceptible and from a resistant (R) plant; (c) a leaf from each of two resistant plants. To prepare a leaf sandwich, a strip of epidermis (2–3 cm. long) was removed from the under surface of each leaf. The exposed mesophyll tissue was bathed in 0.5 per cent water agar to prevent drying of the cells and to act as an adhesive when the two under-surfaces of the leaves were brought together. The margins of the two leaves were then cemented together with paraffin wax. One member of the leaf sandwich, the donor leaf, was inoculated with the uredospores of a given race of the rust. Once the rust mycelium was established in the donor leaf, it advanced in the region where the epidermis had been removed, through the thin layer of agar separating the two leaves, and entered the exposed mesophyll of the uninoculated (receiver) leaf.

The bridging of the rust mycelium from a donor S-leaf to a receiver S-leaf resulted in a susceptible type of infection on both leaves. Bridging from a donor S-leaf to a receiver R-leaf, or vice versa, gave rise, respectively, to a resistant or a susceptible type of infection on the receiver leaf. Bridging from a donor R-leaf to a receiver R-leaf resulted in a resistant type of infection on both leaves. The several results are illustrated in Fig. 1. In the scores of leaf sandwiches made by using the host variety combination Markton (S) and Rodney (R) and race 6 (Fig. 1), Markton (S) and Ajax (R) and race 7A, Markton (S) and Lanark (R) and race 8A, and Markton (S) and C.I. 4023 (R) and race 13A, the infection type was never found to differ from the standard reaction of the particular variety concerned.

Fig. 1. Four different 'leaf sandwiches' showing the development of rust mycelium in donor leaves (left) inoculated with uredospores of race 6 and receiver leaves (right) invaded by the outgrowth of mycelium from the under surface of donor leaves. Susceptible leaf (S) = Markton; resistant leaf (R) = Rodney

The following evidence demonstrates that the failure of the *R*-leaf to show any trend toward a susceptible reaction is not due to the inability of the mycelium in the *S*-leaf to transport 'food materials' to its more remote hyphal extremities in the *R*-leaf. When the epidermis of a donor leaf was removed and the leaf merely maintained in an atmosphere of air saturated with water vapour, masses of aerial mycelium developed on the exposed under surface. This aerial mycelium received its nourishment from the mycelium living in association with the cells of the host leaf. Again, when a sandwich was made of a donor *S*-leaf carrying the radioactive tracer phosphorus-32 and a receiver *R*-leaf free from the tracer element, some of the phosphorus-32 passed through the mycelial bridge from the *S*-leaf to the *R*-leaf. The radioactivity in the *R*-leaf was concentrated at the site of the infection, though a low level of activity occurred in the immediate peripheral host tissue. In this experiment, the two leaf components were kept entirely separate from each other by means of a strip of plastic (0.5 mm. thick) except for a small opening (3 mm. diameter) in the plastic opposite the point inoculated on the donor *S*-leaf. In the absence of mycelium (uninoculated control), phosphorus-32 did not pass from the donor *S*-leaf to the receiver *R*-leaf. These results indicate that the mycelium in the *S*-leaf was able to support its mass extension beyond the confines of the leaf tissue itself and that, indeed, nutrient materials do pass over the mycelial bridge from the mycelium of the susceptible leaf to its more distant extension in the resistant leaf.

If resistance is due to a deficiency or an inadequate availability of the growth medium in the *R*-leaf, the mycelium in this leaf should be able, via the mycelium bridge, to supplement its local food supply from the mycelium in the *S*-leaf. Granted that the supplement received may not be entirely adequate to change the infection type from resistant to susceptible, yet it might reasonably be expected to shift the reaction somewhat in that direction. No such shift has been observed to occur, at least within the time interval of these experiments (14 days after inoculation). Resistance in the oat plant seems, therefore, not attributable to the failure of a resistant plant to supply the factors necessary for the growth of the rust pathogen, but rather to some specific type of inhibition, the nature of which has not been ascertained. The inhibitory mechanism seems not to be operative beyond the resistant tissue because the mycelium is capable of migrating from this tissue to a receiver *S*-leaf and of growing vigorously in it. This fact suggests that the inhibition arises from the interaction of the rust mycelium and the host cells. Details of this work will be published elsewhere.

Grateful acknowledgment is extended to: Dr. H. A. Senn, director, Plant Research Institute, for providing growth room and laboratory facilities; and to Mrs. G. Shaw for technical assistance.

ENTOMOLOGY

Facultative Parthenogenesis in Collembola (Insecta)

PARTHENOGENESIS in insects is well known, and its occurrence in the class is fairly widespread. In the order Collembola (the springtails) its presence has been suggested on rather disputable grounds and then afterwards denied on more than one occasion¹. Choudhuri gave the first real proof of the phenomenon within the order when he described² a new species of Collembola (*Onychiurus parthenogeneticus*). He was able to study this species not only by examination of museum material from Europe and Africa but also by observations on specimens maintained in culture for more than two years. No males of this species were ever seen by him. In all, some forty species of the genus were examined by Choudhuri, and this was the only species in which no males were found. This led to the assumption that the phenomenon may be rather rare in Collembola. Gisin³ placed *O. parthenogeneticus* as a junior synonym of *O. hortensis* Gisin, 1949, and stated that "die Kolonien offenbar meist aus lauter Weibchen bestehen". This synonymy is not upheld by Choudhuri and Goto (in the press), but the two species are obviously very close. The suggestion that at least some males are present in Gisin's species indicates that facultative parthenogenesis might possibly occur in certain circumstances in Collembola.

A number of species of Collembola have been reared in this Department during the past ten years. Among these are two species of the isotomid genus *Folsomia* (*F. candida* Willem and *F. cavicola* Dela-

mare). In both these species, males and females have been found in wild populations in approximately equal numbers. They may easily be separated from each other by the form of the external genital aperture; the sexes are otherwise indistinguishable. Neither pairing of any kind nor the deposition of spermatophores has ever been noted in these species; but it was assumed that the males were functional since the testes were normally developed. Individuals raised from single eggs were kept in isolation and in the case of females produced eggs without ever having been in contact with a male. Great care was taken to ensure that the food and culture dishes were free from any possible contamination with spermatophores. The eggs produced under these conditions were viable and gave rise only to females. From these, completely parthenogenetic cultures were built up. Repetition of these experiments always gave the same results. There is no significant difference in the number of eggs viable nor is there any obvious structural or biological change in the parthenogenetic individuals.

Observations on other genera of Collembola are still in progress and all that can be said as yet is that facultative parthenogenesis is present, but by no means universal in the order.

Antigenic Property of the Oral Secretion of Fleas

THE development of hypersensitivity to bites of blood-sucking insects in man and animals requires an initial sensitization by the insect, or by antigens prepared from the insect. A latent period occurs between the time of the initial exposure and the time when challenge elicits skin reactions characterized by delayed and/or immediate types. Thus B. Hudson *et al.*¹ and Benjamini *et al.*² demonstrated that when guinea pigs were exposed to flea bites they developed an allergic state which required a latent period of 5-7 days for the appearance of delayed reactions, and an additional 2-5 days for the onset of immediate reactions. It was further shown by Benjamini *et al.* that guinea pigs could be sensitized to flea bites by intradermal injection of saline solution containing antigens prepared from fleas, or by the intramuscular injection of such antigens in combination with the complete Freund's adjuvant. When sensitization to flea bites with prepared flea antigens was achieved, the latent period required for the appearance of delayed skin reactions extended from 10 to 14 days, the immediate reaction still appearing within 2-5 days following first appearance of the delayed reaction.

Although most workers have assumed that the specific agent responsible for sensitization and for the allergic reaction is present in the oral secretion ('saliva') of hematophagous insects, this hypothesis lacks direct experimental evidence. By a series of delicate experiments it was recently shown by A.

Hudson *et al.*³ that severing the main salivary duct of mosquitoes prevented allergic reactions to their bites, thus suggesting that the source of the allergen lies in the salivary glands.

It is the purpose of this communication to present direct experimental evidence for the allergenic nature of the oral secretion of fleas. This was achieved by the experimental sensitization of guinea pigs to flea bites with oral secretion of these insects collected *in vitro*.

The oral secretion of laboratory-bred cat fleas, *Otenocephalides felis felis* (Bouché), was collected *in vitro* in distilled water using the apparatus described by Kartman⁴. Approximately 1,000 fleas were confined in each feeding chamber. The insects were allowed to feed for 1 hr. on distilled water, maintained at 37° C., through a highly purified animal membrane⁵. At the end of the feeding period the substrate was collected and lyophilized. The lyophilized product was green-brown in colour and had a somewhat gummy consistency. The yield of the lyophilized product obtained from the feeding of about 100,000 fleas was approximately 100 µgm. The product was then taken up in 15 ml. of saline and filtered through an ultrafine glass filter to remove bacterial contamination. Controls consisted of identical distilled water collection and treatment, but with no fleas confined in the feeding chamber. On lyophilization, the control flask was colourless with no detectable yield.

The animals used were white or albino guinea pigs of mixed sexes weighing 200-300 gm. each. Each animal was injected intradermally twice, at weekly intervals, with 0.5 ml. of the oral secretion or the equivalent control in saline. The oral secretion consisted of 3 µgm. of the final lyophilized product, which is equivalent to the oral secretion collected from the feeding of about 3,000 fleas. With intraperitoneal injections, each animal was given 0.5 ml. of the oral secretion in saline, or in combination with Freund's complete adjuvant⁶. The oral secretion-adjuvant combination was prepared by mixing the oral secretion in saline with an equal volume of adjuvant (thus each intraperitoneal injection contained 1.5 µgm. of the final lyophilized oral secretion, which is equivalent to that collected from the feeding of about 1,500 fleas). The corresponding control was prepared in an identical manner. In addition, two other groups of guinea pigs were used. One consisted of animals each of which received two weekly intradermal injections of 0.5 ml. of 2 mgm./ml. whole flea extract in saline. In the other group, each guinea pig was exposed daily to bites of 20 fleas.

Two weeks following the initial injection, the animals were challenged daily with bites of 20 fleas each until delayed reactions appeared. The challenging procedure follows the method described by Benjamini *et al.*². Results are shown in Table 1.

Results presented in Table 1 show that sensitization to flea bites was achieved when animals were injected intradermally with whole flea extract, and when animals were injected intraperitoneally with oral secretion in combination with the adjuvant. These results demonstrate the presence, in the oral secretion of cat fleas, of a substance or substances which are responsible for the development of hypersensitivity to flea bites in guinea pigs. The fact that the majority of animals injected with whole flea extract, or with oral secretion in combination with adjuvant, reacted to the challenging bite on first exposure demonstrates the ability of the oral secretion to induce

Table 1. INDUCTION OF SENSITIVITY TO FLEA BITES IN GUINEA PIGS BY INJECTIONS OF WHOLE FLEA EXTRACT, FLEA ORAL SECRETION, AND BY FLEA BITES

Method of sensitization	No. of animals used	Flea bite challenge two weeks after initial injection				
		Per cent animals showing delayed reactions on day of exposure				
		First day	Second day	Third day	Fourth day	Fifth day
Flea bites*	20	0.0	0.0	0.0	10.0	100.0
Whole flea extract (intradermal)	20	100.0	100.0	100.0	100.0	100.0
Oral secretion (intradermal)	20	0.0	0.0	0.0	10.0	100.0
Control for oral secretion (intradermal)	20	0.0	0.0	0.0	5.0	100.0
Oral secretion (intraperitoneal)	10	0.0	0.0	0.0	20.0	100.0
Oral secretion with Freund's adjuvant (intraperitoneal)	15	80.0	80.0	80.0	93.2	100.0
Control for oral secretion with Freund's adjuvant (intraperitoneal)	15	0.0	0.0	6.7	26.6	100.0

* Flea bite sensitization began on first day of challenge.

hypersensitivity. In comparison, the corresponding controls reacted only after five daily exposures, when sensitization finally was elicited by the challenging bites. The fact that sensitization was not induced when oral secretion was injected intradermally or intraperitoneally in saline alone suggests that oral secretion contains an incomplete antigen which by itself is incapable of inducing sensitivity. On the other hand, in combination with an adjuvant the oral secretion achieves its full antigenic properties. The observation that animals sensitized to flea bites by bites of fleas do react to skin challenges given with oral secretion is further support of the hypothesis that the substance in the oral secretion responsible for the induction of hypersensitivity shows characteristics of a hapten. It remains for future work to test this hypothesis.

GENETICS

Natural Selection and the Sex Ratio

In a recent article, Kalmus and Smith¹ have attempted to explain why a sex ratio of about one half is selectively advantageous. More recently, Bodmer and Edwards² have published a paper on the same subject. The two approaches differ in the emphasis placed on different forms of selection. Kalmus and Smith believe that there are two main selective forces: one which requires the chance of encounter of a male and a female at the reproductive age to be a maximum, and hence that the sex ratio at this age should be one half (as suggested by Crew³); and the other that the genetic variance of a population should be as large as possible for a given population size, which also requires a sex ratio of one half at sexual maturity. On the other hand, Bodmer and Edwards maintain that the most important selective force arises through the advantage of reproducing as efficiently as possible, that is, of making the maximum genetic contribution to future generations for a given amount of effort devoted to the bearing of young. As Fisher⁴ pointed out, a sex ratio of about one half is the most efficient in this sense.

The fundamental difference between these two approaches lies in the mode of selection. The types of selection that Kalmus and Smith believe important can only operate *between* populations, whereas the latter, or Fisherian, type can only operate *within* a population. Thus Kalmus and Smith maintain that populations with sex ratios about one half are common because they have replaced populations with other sex ratios, while Fisher's argument supposes that even an isolated population will evolve towards a sex ratio of one half. It is thus clear that only in exceptional circumstances will a population be at a selective advantage over a competing population on account of its sex ratio since both will already have evolved a sex ratio of one half.

If interpopulation selection were of paramount importance in determining the sex ratio one would expect to have found that isolated populations, which are not subjected to it, frequently had sex ratios different from one half, which has not been observed. Furthermore, in polygamous species in which a single male, after defeating his competitors, fertilizes a large number of females, there is no longer any reason for it to be advantageous if the chance of encounter of a male and a female is at a maximum: prolific reproduction is ensured only if there is a plentiful supply of females and the sex ratio is very low. The fact that the genetic flexibility of the population is then somewhat restricted is unlikely to outweigh the advantages of such a sex ratio in interpopulation selection, where the ability to breed large numbers is of particular importance. Nevertheless, the sex ratio in such species seems to be about one half.

Kalmus and Smith concede the relevance of Fisher's theory when they state that "in the case of species which rear their young, a further reason for expecting equality of sex-ratio at the time of sexual maturity has been given by Fisher". But this is a misrepresentation of what Fisher actually wrote: his argument refers not only to species which *rear* their young, but also to species in which reproduction involves some expenditure of effort by the parents—

that is, to all sexually reproducing species. Furthermore, as Bodmer and Edwards have shown, it is not equal numbers of the sexes at maturity that is expected but equal numbers at the end of the period of parental dependence.

It thus seems that Kalmus and Smith have not fully appreciated the force of Fisher's argument. When the two points of view are compared in detail there is little doubt that it is Fisherian selection that is primarily responsible for the observed numerical equality of the sexes in many species.

Chromosome Breakage induced by electrolytically produced Free Radicals

IN assessing the mode of action of radiations in biological systems, the free radicals have been recognized as playing an important part in producing the end effect¹. It has also been shown that chemically produced free radicals (hydroxyl ions from hydrogen peroxide plus iron ions) are capable of inducing chromosome breakage in barley². In the present work, attempts were made to study the biological effects of free radicals and secondary products produced electrolytically by the well-known Kolbe synthesis³ in which the anode reaction can be described as follows:

Reaction 2 is accompanied by release of energy. Although the possibility that this energy may be emitted as light is certainly very low (about 1 in 10¹⁰), it can be measured by means of a sensitive photon-counting detector system. The life of the light-emitting species can be measured by applying the pulses from the photomultiplier tube to a rate-meter circuit on an oscilloscope. The emission spectrum was recorded by means of six interference filters (350–700 mμ).

We have observed that when different plant oils react with alkaline buffers, there is a simultaneous emission of light during the reaction. The energy of the light emitted varies with different oils. At present it is not clear as to whether the light comes from the reacting radicals or from the decomposition of peroxides. However, the light-energy can be correlated with the mutagenic ability of the oils^{4,5}; mutagenic oils emit light of higher energy than the non-mutagenic oils.

Similarly, it is possible by electrolysis of some simple amino-acid solutions to produce reactive species with different light 'emission energy' and different length of life; for example, tyrosine gives reactive species with high energy and long life, whereas cysteine, known as affording protection from radiation, gives light with low emission-energy and short life (high energy refers to quanta of 2.7–

3.0 eV., low to about 2.4 eV.). Furthermore, when both tyrosine and cysteine are present during electrolysis, light emission and length of life were the same as in cysteine electrolysis⁶.

In the present work we have used tyrosine and cysteine as a 'model system' and barley root meristems as the biological material, since the latter is known to be an extremely stable cytological material (ref. 7 and Ehrenberg, L., and Natarajan, A. T., unpublished work). Freshly germinated barley seeds (with roots about 5 mm. long) were placed with their root tips on a platinum anode and electrolysed (4.5 V.) for 1 hr. in the following solutions:

- (1) Sodium acetate (0.06 M)
- (2) " " + tyrosine (saturated)
- (3) " " + cysteine (0.01 M)
- (4) " " + " " + tyrosine (saturated)

After treatment, the seeds were washed and allowed to recover for 18 hr. The root tips were fixed in acetic alcohol (1:3) and slides were prepared as Feulgen squashes. The slides were scored for chromosomal aberrations at both metaphase and anaphase stages. The results are presented in Table 1. Two sets of controls were treated for 1 hr. without electrolysis in different solutions as well as in solutions which had been electrolysed for 1 hr. At least two hundred cells were scored for each treatment and no cytological abnormalities could be detected in this material. Material electrolysed in tyrosine exhibited at least a ten-fold increase in chromosome breakage over the rest of the treatments. It is of interest to note that by the addition of cysteine to the system, the effect of tyrosine could be nullified.

Table 1

Solution electrolysed	No. of cells studied	Aberrant cells (per cent)	Aberrations (per cell)
(1) Sodium acetate (0.06 M)	722	0.41	0.0041
(2) Sodium acetate (0.06 M) + tyrosine	172	5.80	0.0820
(3) Sodium acetate (0.06 M) + cysteine	414	0.23	0.0023
(4) Sodium acetate (0.06 M) + cysteine + tyrosine	215	0.47	0.0047

In the genetic material there are obviously chemically reactive groups susceptible to radiomimetic agents such as radicals, peroxides, epoxides, etc. To get a reaction, the radiomimetic agent and the reactive group in the nucleus must have more energy than the possible reaction products. If we assume the reactivity of the actual genetic material to be constant, then the energy content of the radiomimetic substance determines if a reaction will take place or not.

The results from the experiments mentioned above together with the emission spectroscopic measurements⁶ on various substances make it reasonable to assume that the energy of the emitted light is an expression of reacting potential towards other molecules⁸ (this is not valid in the case of molecules where the excited state is protected against external chemical reactions). Then it is possible, by means of emission spectroscopy, to screen reactive species from a radiobiological point of view.

In our experiments, the reactive species are produced outside the cell and must have a long life to reach critical sites inside the cell. Though the kind of reactive species involved is not clear at present, it is of interest that such types of species are certainly produced in irradiated biological systems also.

The occurrence of low energy-levels in the chromosome with high polarizability of electrons in these

levels makes it possible to assume that the reactivity of the genetic material is highly dependent on the chemical environment, for example, as determined by water content. Perhaps this polarizability can be increased by addition of particular substances and cause the reactive groups to be even more reactive towards radiomimetic agents. This problem is under investigation.

The financial support of the Swedish Cancer Society and the Swedish Natural Science Research Council for these investigations, and an award of a fellowship to one of us (A. T. N.) by the Swedish Institute, are gratefully acknowledged.

ANTHROPOLOGY

The Olduvai Giant Hominid Tooth

THE giant molar tooth found by Dr. L. S. B. Leakey¹ in Bed II at Olduvai Gorge in Tanganyika was reported by him^{1,2} to be a lower deciduous second molar of a hominid, possibly related to *Smantropus* and *Homo heidelbergensis*. This interpretation has been questioned by a number of workers including G. H. R. von Koenigswald³ of Utrecht and John T. Robinson⁴ of Pretoria, who conclude that the tooth is rather a permanent upper molar, probably *Australopithecine*.

I am in agreement with the views of the last two authors on all but one point, that is, the contention that it necessarily is a permanent tooth. Its size certainly places it in the range of the *Australopithecine* permanent molars (including those of *Zinjanthropus*), but several things make it difficult to rule out the deciduous grouping.

Beyond a doubt the root system is that of an upper molar. There are three roots, two obviously buccal and the large lingual one extending palatally in the typical fashion which required that it had the accommodations of the maxillary alveolus rather than the restrictions of the mandibular bony support. The cast of the tooth, available to me through the courtesy of Dr. K. P. Oakley of the British Museum (Natural History), suggests also that the roots may have been in the process of resorption from the influence of the developing permanent tooth which nestled above and between them. This may be questioned, though, by the fact that lack of wear suggests that the tooth is not old enough to be in the resorptive stage. The spreading disposition of the roots with the markedly constricted neck of the tooth strongly suggests a deciduous character.

The occlusal surface of the Olduvai tooth is long and narrow, as outlined by the tips of the cusps.

Table 1. LENGTH AND BREADTH OF UPPER MOLARS

	MD lg	BL br	M ₁ MD lg	M ₁ BL br	M ₂ MD lg	M ₂ BL br
Olduvai tooth	15	14				
<i>Zinjanthropus</i>			15.5	18.0	17.0	21.0
<i>Australopithecus crassidens</i> Swartkrans 89 (av.)			14.6	15.0		
<i>Australopithecus crassidens</i> Swartkrans 27 (av.)			14.0	13.2		

This is a feature seen mainly on deciduous teeth, although it does occur on the permanent ones but much less frequently. The strong development of the metacone also speaks in favour of this being a deciduous rather than a permanent tooth.

Robinson's points on the relative position of the buccal and lingual cusps, the intercuspal crest and the accessory cusps in the fovea, are valid. So is his argument against the heavily worn deciduous canine belonging to the same individual from which the molar came. Von Koenigswald used an index based on mesio-distal crown lengths to compare the tooth sizes in *Homo*, *Australopithecus* and the Olduvai specimen. He felt that the value of 214 for the latter placed it definitely within the range of *Australopithecus*, which had indexes of 148 and 187 as contrasted to 117 and 153 for *Homo*. The tooth dimensions of *Zinjanthropus boisei* (from Bed I in the same gorge)⁵ were not available to him at the time. The difference in size between anterior and posterior teeth in *Zinjanthropus* is so considerable that applying von Koenigswald's index to the permanent first molar of the latter and the Olduvai deciduous canine⁶ gives a value of $228 = \left(\frac{15.5}{6.8} \times 100 \right)$. An Olduvai deciduous

second molar would be expected to be smaller than this, and hence comes closer to the measurement of the giant Olduvai tooth being discussed. Thus, the argument of size and proportions favours rather than discounts the identification of the Olduvai molar as a deciduous tooth.

In my opinion, therefore, the Olduvai molar could very well be a left maxillary deciduous second molar.

PSYCHOLOGY

Senile Dementia and Cerebral Oxygen Uptake measured on the Right and Left Sides

In a recently concluded work¹ on cerebral oxygen uptake in the aged, an unexpected result was that uptake values based on blood drawn from the left internal jugular vein were more closely related to mental function than were values based on right jugular blood. Five normal aged men and nine male

patients with chronic brain syndrome were included in this part of the investigation. Bilateral cerebral oxygen uptake determinations were made with Lassen and Munck's modification² of the inert gas method of Kety and Schmidt³. This modification employs krypton-85 as the inert gas, and bilateral simultaneous sampling of internal jugular blood is carried out. Psychological functioning was assessed by the Wechsler adult intelligence scale and Raven's matrices⁴. The physiological and psychometric data were not compared until after completion of the investigation.

Table 1 lists the correlations obtained between the Wechsler adult intelligence scale sub-tests and matrices scores, and the cerebral oxygen-uptake values of the right and left sides. One patient was aphasic and unable to perform any psychological tests, and other patients did not complete all tests; the numbers for the several correlations therefore vary. It will be seen that the correlations are consistently higher on the left and that many are statistically significant. None of the correlations on the right achieves statistical significance. The values of cerebral oxygen-uptake for the two sides were negatively but not significantly correlated, $r = -0.14$.

Table 1. CORRELATIONS OF CEREBRAL OXYGEN UPTAKE VALUES* MEASURED ON THE RIGHT AND LEFT SIDES WITH PSYCHOMETRIC TESTS

Wechsler adult intelligence scale sub-tests	Correlation with central oxygen uptake values		
	No.	Right	Left
Block design	12	0.22	0.63*
Similarities	13	0.16	0.60*
Digit span	13	0.04	0.32
Picture arrangement	10	-0.13	0.77†
Picture completion	10	0.00	0.62*
Digit symbol	9	0.38	0.57
Arithmetic	13	0.13	0.57*
Information	13	0.04	0.61*
Vocabulary	13	0.04	0.41
Progressive matrices	10	0.18	0.44

Uptake right versus uptake left, $r = -0.14$.

* $P < 0.05$; † $P < 0.01$.

* The uptake values with which the correlations of Tables 1 and 2 were computed are 'infinity' values, based on extrapolation of the venous curve (cf. discussion in ref. 1). Correlations based on 10-min. values, available in this work, showed an even more marked difference in favour of the left side.

In order to evaluate this finding further, correlations were computed on data available from previous work by Lassen *et al.*⁵, which employed the same physiological techniques and similar psychometric methods on a population resembling our own. These correlations are listed in Table 2. It will be seen that the correlations are again consistently higher on the left, though the difference between sides is slight. However, in this work the cerebral oxygen uptake values on the right and left sides were themselves positively and significantly correlated ($r = +0.58$). Therefore, partial correlations were computed; these indicate the relatively independent relationship to the psychometric data of the uptake values of each side. The results are listed in parentheses in Table 2. It will be seen that this procedure enhances the difference between sides: three of the four correlations on the left remain statistically significant, while none on the right does so.

These findings therefore suggest that cerebral uptake values based on right and left jugular blood have different significance for the aspects of mental function measured by the psychological tests. How may this difference be interpreted? One possibility is that uptake values based on jugular blood samples reflect predominantly the state of cerebral metabolism in the ipsilateral hemisphere. If this were so,

Table 2. CORRELATIONS OF CEREBRAL OXYGEN UPTAKE VALUES WITH PSYCHOMETRIC TESTS

Calculated from data available from a previous bilateral study. Partialled correlations in parentheses. $N = 13$

Psychometric test	Correlation with cerebral oxygen uptake values	
Wechsler adult intelligence scale sub-tests	Right	Left
Block design	0.59† (0.27)	0.72† (0.58)†
Similarities	0.43* (0.16)	0.57† (0.44)*
Digit span	0.34 (0.12)	0.44* (0.31)
Progressive matrices	0.59† (0.27)	0.72† (0.58)†

Uptake right versus uptake left, $r = 0.58†$.

* $P < 0.05$, † $P < 0.01$.

we might relate our findings to hemisphere dominance (12 of the 13 subjects were right-handed) and to the oft-noted special importance of the left side of the brain for intellectual function. (The relative importance of left and right hemisphere lesions as causes of cognitive impairment in man is not a settled issue. It has been well established that those intellectual functions closely related to or dependent on language are more severely impaired by lesions of the left hemisphere⁶. However, recent psychological work has yielded evidence that skill on certain 'non-verbal' or 'performance' tasks is reduced more by right than by left cerebral lesions⁷. It should be noted that, in our investigation, the 'performance' as well as the 'verbal' tasks of the Wechsler adult intelligence scale were more highly correlated with left cerebral oxygen uptake values.) However, the degree of intermixture of venous blood from the two hemispheres has not been definitely established. A study⁸ of intra-carotid injection of T-1824, carried out in five normal subjects, found a mean ratio of dye recovery from the internal jugular veins (contralateral: ipsilateral) of 1:3. It can be shown mathematically that correlations of the magnitude we report here are not incompatible with this degree of intermixture. (We are indebted to Dr. S. Geisser, of the Biometrics Branch, National Institute of Mental Health, for this proof and for other statistical advice.) However, until the sources of blood draining into the jugular veins are more fully determined, it would be premature to interpret the difference in correlation with mental state as the result of a general metabolic difference of the respective hemispheres. It remains conceivable that it is the metabolic activity of a localized brain area, the drainage of which is strictly unilateral, which is the significant variable.

An alternative possibility is that the two sides have differing proportions of cortical/subcortical blood, and that it is some aspect of this ratio which is reflected in the differing correlations with mental state. However, while anatomical evidence suggests that frequently one side receives the larger proportion of cortical blood, neither side appears to be consistently favoured⁹. Further, bilateral cerebral oxygen uptake determinations in normals have failed to reveal significant differences between the right and left sides^{1,2}; if one side consistently drained more cortical blood, one would expect its metabolic rate to be higher.

Whatever their underlying basis, our findings raise the possibility that cerebral oxygen uptake values on the right and left sides may not be of equal significance for mental function. If so, previous unilateral studies, which were performed predominantly on the right side and which failed to show any relationship to psychological variables¹⁰, require re-evaluation. Reliable correlations between physiological and mental states have been notoriously

difficult to establish. It now appears possible that application of the bilateral method may considerably enhance the significance of cerebral oxygen uptake measurements and thus offer new opportunities for research in this area.

The Relativity of Meaning

THE burden of Dr. Ross Ashby's communication¹—"the meaning of a message also depends on the set that the message comes from" is known to every careful user of the English language who has learnt the meaning of the word 'context', but his example is incomplete. The messages that he instances may indeed change their meanings as the set is expanded, but "How we wish you were here" does not necessarily become ironic because "Do come and join us" is available as well. If the sender knows that such joining is impossible he may honestly choose the former message, which will then have the same meaning as if it were the only one of the two available. The set is of less importance in determining meaning than is the mutual knowledge that sender and recipient have of one another.

¹ Ashby, W. Ross, *Nature*, **187**, 532 (1960).

DR. ROSS ASHBY¹ advocates the "postulate that the meaning of a message [as well as its information content] . . . depends on the set of messages that the message comes from". It seems possible that Dr. Ashby was thinking primarily in terms of non-natural languages (such as those used as models in information theory). However, his example is drawn from natural language, and presumably his argument is meant to apply to all languages.

If this is so, I suggest that his point should be thought of as a special case of a quite general rule of language, when it is used to express empirical information. It is normally true that the meaning given to an empirical statement (a message) both by the deliverer and by the receiver will depend on a number of factors in addition to its 'intrinsic' properties; that is, the shapes and ordering of its signs.

The most influential of these factors is the 'purpose' of the statement, which in its turn determines what is its mode of justification or verification, what is the relevant 'set of messages' (context), how much the statement is to be taken as elliptical, and so on; all these are, of course, themselves part-determinants of meaning—of how a statement will be interpreted. Obvious examples are "That object has a low temperature" (in the kitchen or in the laboratory?), "That hill is dangerous" (for motor-cars or aeroplanes?) and "Water is H₂O" (definition or description?).

In current linguistic theory, such cases are treated as exceptions. But in fact there are reasons² for thinking that a great deal of trouble could be saved, not only within the field of communication theory but also in controversy in general, if it were regarded as the rule that the way in which sentences (and sometimes individual words) are to be interpreted depends in part on the purpose for which they are used.

MATHEMATICS

Theory of Optimal Gammas

ROSS¹ asks for a definition of the goodness of a game. A reasonable answer, though presumably incomplete, is that a game is good in so far as it involves skill. A measure, γ , for the degree to which a game is one of skill may also be of legalistic interest in those countries where gambling is somewhat against the law. Several years ago I suggested a definition for γ , and it may now be appropriate to publish it. The definition is relative to a population of learners and trainers and to the number of learners, and is relative to the training time and to the duration of play. If we assume all these parameters to be fixed we should find that the players would fall into γ grades, $C_1, C_2, \dots, C_\gamma$, such that, on average, a player in grade C_q would have a probability of say $2/3$ of beating a player in grade C_{q+1} ($q = 1, 2, \dots, \gamma - 1$). The number, γ , of grades, is then the suggested measure of the degree to which the game is one of skill. It is not a good measure of difficulty, since some games, such as the child's game of 'boxes', are so difficult for human beings that training and ability do not count for much.

FORTHCOMING EVENTS

(Meeting marked with an asterisk * is open to the public)

Monday, December 12

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATION SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. P. B. Bryant: "Topology Concepts in Network Theory".

INSTITUTE OF METAL FINISHING (at the Northampton College of Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Mr. J. M. Kape: "Unusual Anodizing Methods and Their Practical Significance".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Brig. Bernard Fergusson, D.S.O., O.B.E.: "A Return to Upper Burma".

Tuesday, December 13

ILLUMINATING ENGINEERING SOCIETY (at the Federation of British Industries, Tothill Street, London, S.W.1), at 6 p.m.—Mr. J. M. Waldram: "Visual Problems on Motorways".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. J. P. Soltan: "Maximum Cylinder Pressure Fluctuations in a Petrol Engine".

BRITISH INSTITUTION OF RADIO ENGINEERS, ELECTRO-ACOUSTICS GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. G. D. Browne: "A Pulse Multiplex Stereophonic Broadcasting System".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, W.C.2), at 6.30 p.m.—Sir Hamish D. MacLaren, K.B.E., O.B.: "Electrical Engineering in the Naval Service".

INSTITUTION OF THE RUBBER INDUSTRY (at the Royal Overseas League, Park Place, St. James's, London, S.W.1), at 5.30 p.m.—Mr. E. E. Gunn: "Some Radiation Effects on Rubbers". 7 p.m.—Panel Discussion—"Competitive Polymers in Automobile Applications". Speakers: Mr. A. E. Bray, Mr. S. Mottran, Dr. L. Mullins, Mr. G. B. Oks, Mr. J. Walker, Dr. W. Stein and Mr. C. H. Gregory.

Wednesday, December 14

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 2.30 p.m.—Discussion Meeting on "Automatic Methods of Handling Meteorological Data". Principal Speakers: Mr. C. V. Elise, Mr. J. M. Craddock and Mr. E. J. Sumner.

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Mr. R. H. Daw: "The Comparison of Male and Female Mortality Rates".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. A. C. Stevenson: "Modern Trends in the Population Genetics of Man".

INSTITUTION OF ELECTRICAL ENGINEERS, SUPPLY SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. L. Gosland and Mr. K. G. Parr: "A Basis for Short-Circuit Ratings for Paper Insulated Cables up to 11 kV."; Mr. G. S. Buckingham: "Short-Circuit Ratings for Main Cables".

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. D. F. Galloway: "Machine Tool Research, Design and Utilization" (James Clayton Lecture).

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMISTRY GROUP (in the Restaurant Room of "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion Meeting on "A Review of Topics in Organic Micro-analysis".

SOCIETY FOR PSYCHICAL RESEARCH (at Kensington Town Hall, Kensington High Street, London, W.8), at 7 p.m.—Mr. R. B. Warr: "Levels of Awareness—Their Relevance to Psychical Research".

WOMEN'S ENGINEERING SOCIETY (at "Hope House", 45 Great Peter Street, Westminster, London, S.W.1), at 7 p.m.—Capt. F. Potts: "Power Transmission by Submarine Cable".

Thursday, December 15

ASSOCIATION FOR THE STUDY OF ANIMAL BEHAVIOUR (at Birkbeck College, Malet Street, London, W.C.1), at 10.45 a.m.—Symposium on "The Effects of Chemicals and Drugs on Behaviour".

INSTITUTE OF PHYSICS and the PHYSICAL SOCIETY, OPTICAL GROUP (in the Physics Department, Imperial College, Prince Consort Road, London, S.W.7), at 2.30 p.m.—Dr. C. G. Wynne: "A Flat Field Microscope Objective"; Mr. R. W. Uffen: "The Field for Fibre Optics".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 2.30 p.m. and 5.30 p.m.—Scientific Papers.

INSTITUTION OF MINING and METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. H. Dalton-Brown: "Recovery of Cassiterite at the Sungai Besi Mines, Selangor, Malaya"; Mr. F. A. Williams: "Recovery of Fine Alluvial Cassiterite: Correlation of Bore Valuations with Plant-Scale Recovery".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. R. C. Lyndon: "Projective Geometry and the Algebra of Relations".

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, London, W.C.2), at 6 p.m.—Discussion on "How to Pass Examinations or the Psychology of Study" opened by Prof. C. A. Mace.

INSTITUTION OF MECHANICAL ENGINEERS, NUCLEAR ENERGY GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "The Impact of Three-Fuel Economy".

Thursday, December 15—Friday, December 16

POWDER METALLURGY JOINT GROUP OF THE IRON and STEEL INSTITUTE and the INSTITUTE OF METALS (at Church House, Great Smith Street, London, S.W.1), at 2.30 p.m. on Thursday and 9.30 a.m. on Friday—Winter Meeting.

Friday, December 16

ASSOCIATION FOR THE STUDY OF ANIMAL BEHAVIOUR (at Birkbeck College, Malet Street, London, W.C.1), at 10 a.m.—Symposia on "The Acquisition of New Behaviour Patterns" and "Releasing Stimuli in Animal Behaviour".

BIOCHEMICAL SOCIETY (in the Physiology Theatre, Guy's Hospital Medical School, London, S.E.1), at 10.10 a.m.—401st Meeting.

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—"The Single-handed Trans-Atlantic Race".

Friday, December 16—Saturday, December 17

BRITISH PSYCHOLOGICAL SOCIETY (at University College, Gower Street, London, W.C.1)—Conference.

Saturday, December 17

NUTRITION SOCIETY (at the Middlesex Hospital Medical School, Mortimer Street, London, W.1), at 10.15 a.m.—Symposium on "Calorie Balance in Man".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER (Grade II) IN PURE MATHEMATICS—The Registrar, The University, Bristol 8 (December 14).

BOOTS FELLOW (with a medical or honours degree in science), for research work under the Professor of Bacteriology—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital Medical School, London, W.2 (December 30).

ASSISTANT LECTURER IN ASTRONOMY—The Registrar, The University, Manchester 13 (December 31).

LECTURER (with a degree in bacteriology or equivalent qualification) in BACTERIOLOGY—The Secretary, The West of Scotland Agricultural College, 6 Blythwood Square, Glasgow, C.2 (December 31).

LECTURER IN PHYSICS at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, January 13).

CHAIR OF CIVIL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (January 14).

ASSISTANT LECTURER (with special qualifications in experimental physics, astronomy or astronomy) in APPLIED MATHEMATICS (GEOPHYSICS)—The Secretary, The Queen's University, Belfast (January 15).

LECTURER IN ORGANIC CHEMISTRY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 15).

SENIOR LECTURERS (2) (one an ANALYST); a LECTURER; and an ASSISTANT (teaching duties and research) in THE DEPARTMENT OF MATHEMATICS—The Secretary, The University, Aberdeen (January 16).

SENIOR LECTURER or LECTURER IN PARASITOLOGY in THE DEPARTMENT OF ZOOLOGY, University College Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 20).

READER, and a LECTURER in THE DEPARTMENT OF AGRICULTURAL CHEMISTRY at the Waite Agricultural Research Institute, University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 30).

IMPERIAL CHEMICAL INDUSTRIES RESEARCH FELLOWS in PHYSICS, CHEMISTRY, BIOCHEMISTRY, ENGINEERING, METALLURGY and PHARMACOLOGY or any related subjects—The Registrar, The University, Liverpool (February 11).

LECTURER in MICROBIOLOGY in THE FACULTY OF MEDICINE, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, February 28).

ASSISTANT BIOCHEMIST (with a first- or second-class honours degree in chemistry or biochemistry, or A.R.I.C.) in THE AREA PATHOLOGY LABORATORY, Stoke Mandeville Hospital—The Administrative Officer, Stoke Mandeville Hospital, Aylesbury, Bucks.

ASSISTANT PROFESSOR, and an ASSOCIATE PROFESSOR in MATHEMATICS—J. W. Lawson, Head of the Department of Mathematics, University of Manitoba, Winnipeg, Manitoba, Canada.

LECTURERS and ASSISTANT LECTURERS in BOTANY; LECTURERS in PHYSICAL and INORGANIC CHEMISTRY, and ASSISTANT LECTURERS in ORGANIC and IN PHYSICAL CHEMISTRY; a LECTURER (preferably with qualifications in algebra or topology) in MATHEMATICS; and LECTURERS and ASSISTANT LECTURERS in both EXPERIMENTAL and THEORETICAL PHYSICS—The Secretary to the Council, Westfield College (University of London), Hampstead, London, N.W.3.

POSTDOCTORAL FELLOW IN THE DEPARTMENT OF CHEMICAL ENGINEERING, for research in flame spectroscopy or a related subject—Dr. A. G. Gaydon, F.R.S., Imperial College of Science and Technology, London, S.W.7.

SCIENCE GRADUATE (with experience in the bacteriological aspects of chemical disinfection) in the DISINFECTANT REFERENCE LABORATORY—The Director, Central Public Health Laboratory, Colindale, London, N.W.9.

SENIOR RESEARCH FELLOW (with a degree in chemical or mechanical engineering, metallurgy or physics, and prepared to conduct research on the engineering principles which underlie processes used for metal extraction, that is, on mass, heat or momentum transfer), IN PROCESS ENGINEERING—Prof. F. D. Richardson, Metallurgy Department, Imperial College of Science and Technology, London, S.W.7.

YOUNG LADY (with B.Sc. in chemistry or a biological science), to assist in a research programme on the Medical Professional Unit—The Secretary of the Medical College of St. Bartholomew's Hospital, West Smithfield, London, E.C.1.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Philosophical Transactions of the Royal Society of London. Series B: Biological Sciences. No. 700, Vol. 243 (18 August, 1960): The Fine Structure of the Insect Ear. By H. G. Gray. Pp. 75-94 + plates 4-15. (London: Royal Society, 1960.) 25s. [129]

Tweed River Purification Board. Annual Report for the year ended 15th May, 1959. Pp. 24. (Newtown St. Boswells: Tweed River Purification Board, 1960.) [129]

PROSPECTS FOR EDUCATION IN BRITAIN

THE debate in the House of Commons on H.M. the Queen's Address from the Throne was notable for the choice of education for a full-day debate on November 7, and in speaking in the debate the Minister of Education, Sir David Eccles, said that he thought this was unprecedented. Sir David covered many aspects in his speech, beginning with a reference to the public library service. He had hoped a Bill could have been introduced during the session, but further study had been found necessary; and there seemed to be agreement that a new Act could not come into operation until the reviews of the local authority boundaries had been completed. One difficulty was in determining the qualifications of a library authority. Sir David thought that the recommendations of the Roberts Committee would not do justice to some of the good work being done to-day, and that further examination from a technical point of view might help in reaching a larger measure of agreement among those with expert knowledge of the service. Sir David also said that the Government is considering its policy in relation to sport, which would take due account of recommendations coming from the committee under Sir John Wolfenden appointed by the Central Council of Physical Recreation. The Ministry of Education is spending about £8 million a year on playing fields, swimming baths, etc., for the schools and technical colleges being built under the regular education programme, and extra resources will be available for the youth service in 1962-63. He thought, however, that there is scope for more co-operation in the use of existing facilities. Sir David also mentioned that a handbook on Commonwealth studies, written by a group of H.M.'s inspectors of education, is being issued as a guide to a subject which he believed the House wished to see widely taught.

Sir David believes that everything possible is being done in Britain to get more teachers for schools. He does not think we could have increased earlier the number of places in the general teacher training colleges from 23,000 to 47,000; the present programme came on top of the building programme for schools and technical colleges, which was already stretching the resources of many local education authorities. Colleges of 500 places and more have already been authorized in London, Loughborough, Coventry, Leeds, Sheffield, Exeter, the Liverpool area and in North Wales, and entirely new colleges are to be built in Cardiff, Canterbury, Brighton and in the Nottingham, Oxford, West Midlands and other areas. Of the places so far approved, 60 per cent will be provided by local authorities and 40 per cent by the churches and voluntary bodies, and Sir David paid a tribute to the part played by the churches. He also

welcomed the prospect of a greater number of graduate teachers, and, with the expansion of the universities, he hoped that more graduates, particularly women, would teach in the primary schools. He believes that our aim should be to establish a two-way link between the training colleges and the universities. Something should also be done about the wastage of women teachers, and a campaign on a national scale to learn more about the availability of the 50,000 or more qualified women teachers who had left the service but had not reached the age of retirement would reach its peak in the new year. The pattern of part-time teaching also requires study, and he hoped for some thorough research into this subject by one or two local authorities.

As regards the supply of graduates, the Government is giving much thought to the development of full-time higher education as a whole, and the Prime Minister is to make an announcement very shortly as to this inquiry. Neither Sir David Eccles nor Mr. John MacLay, Secretary of State for Scotland, replying on the debate, would commit the Government as to whether or not there would be a separate inquiry for Scotland. On university awards, Sir David repeated the earlier announcements regarding the eligibility of a student for an award if he got a place at a university and had two passes at Advanced Level in the General Certificate of Education, the abolition of State scholarships after the selection to be made in the summer of 1962, and the retention of up to £100 a year by winners of open scholarships and other university awards. As a result, he hoped to see the foundation of scholarships at provincial universities, and he would shortly announce a radical revision of the means test, which, he said, has proved to be a more complicated matter than anticipated.

Referring to technical education, Sir David said that students taking full-time and sandwich courses at the colleges of advanced technology have risen from 4,000 in 1955-56 to nearly 8,000 in 1959-60, and an increase to 14,000 in a few years is expected. He is also anxious that these colleges should vigorously develop applied research, and that all technical colleges should develop as centres of further education in the widest sense, serving the whole of the community in their area. Sir David noted that these colleges are drawing their students from all types of school, but he pointed out that the biggest problem is that of students between the ages of 15 and 18, and how many are not getting the education we wish to give them. Although nearly 500,000 students are benefiting from day release, the annual rate of increase has slowed down, and important decisions must be taken between possible lines of advance. It has been

decided to give priority to reducing the size of classes in schools, but discussions with the local education authorities and industry regarding day-release have commenced in a promising atmosphere. However, he pointed out that we may sooner or later have to choose between placing the primary responsibility for training young workers in industry and the French system under which about a third of their young people receive their further education and initial industrial training before entering employment.

In concluding, Sir David referred to the urgent need for more and better technicians. He said that the Ministry has during the past year been reviewing, reconstructing and bringing up to date the whole pattern of courses for some 500,000 technicians, craftsmen and operatives. He also referred to the wastage in further education and said that it should be possible to reduce this drastically, though not to eliminate it altogether. Sir David also mentioned that detailed proposals for technical education will be announced shortly.

Although there was some sharp criticism of the Government's educational programme in the debate, this was mainly on party political lines, and comparatively little that was constructive emerged. Mr. A. Neave suggested that Britain needs much better criteria as to the numbers of scientists and technologists required, and Mr. J. Boyden thought that the Chancellor of the Exchequer and the Minister of Education should have concerted lines of development and seen that the University Grants Committee is provided with adequate staff to work out plans for the expansion of university and technological education. He also commented on the importance of the universities themselves doing more to explain their policies and ensure public understanding and support.

Particular attention was given to the question of wastage; Miss H. Anderson, for example, pressed the point in relation to full-time education, on which she pointed out that very little research had yet been undertaken. A detailed analysis by Dr. D. MacIntosh of students in Fife holding bursaries had indicated a rate of failure of more than 16 per cent, compared with the agreed overall wastage of about 17 per cent indicated by investigations by Sir James Mountford at Liverpool, Dr. Malleson at University College, London, and by the University Grants Committee. Miss Anderson was also very disturbed at a rate of failure of 38 per cent in the science faculty as compared with 10 per cent in the arts faculty. Mr. W. Hannan was more concerned with the wastage in part-time education, and with the unsatisfactory position of day-release in Scotland, and Mr. John MacLay, in replying on the debate, agreed as to the need for more careful study of the causes of wastage. He also agreed that Scottish industry as a whole does not appear to recognize the contribution which day-release could make to the training of young employees; the number of day-release students in Scotland has risen from about 28,000 in 1955-56 only to 35,600 in 1959-60; but it is intended to provide 100,000 places in Scotland by 1965, and the

opening of the new technical colleges should stimulate development.

Many of the points raised in the debate, particularly regarding university expansion, the functions of the technical colleges, etc., are clearly matters which will be referred to the inquiry into further education as a whole; and there was a welcome disposition in the debate to look at education in the broadest sense, though it would undoubtedly be to the advantage of all if there was less disposition to seek party political or even sectional advantage.

JET PROPULSION ENGINES

Jet Propulsion Engines

Edited by O. E. Lancaster. (High Speed Aerodynamics and Jet Propulsion, Vol. 12.) Pp. xvii+799. (London: Oxford University Press, 1959.) 140s. net.

THE teaching of up-to-date aerodynamics has always been hampered by a dearth of good textbooks and reference works. The main reason for this has been the very high rate of progress in all branches of the field, due to the vast resources which the major countries have invested in the development of aeroplanes; the impetus being mainly from the military pressure of two World Wars. The output of data has consequently been immense, and while much of the information has been disseminated in the publications of various specialized bodies, such as the Aeronautical Research Council and the Royal Aeronautical Society in Britain and similar bodies in other countries, the sheer volume of printed reports has made it difficult for the young scientist or engineer to obtain a good grasp of the subject. To add to his difficulties, a large proportion of new aeronautical information has always had a military security value in the country of origin, and there has therefore been delay, sometimes serious, in its open publication.

It is therefore highly desirable to attempt to make periodically a review of the 'state of the art' in aeronautics, and the need for a really vigorous attack on the problem led to the formation in 1949 at Princeton University of an Aeronautics Publication programme which has culminated in the publication of twelve large volumes, treating in both a comprehensive and fundamental manner practically all aspects of aeronautics and jet propulsion and such allied sciences as thermodynamics, physics of matter, nucleonics and so on. That the editorial board consisted of Profs. Theodore von Kármán, Hugh Dryden and Sir Hugh Taylor guaranteed the high standard of the contributing authors, who were chosen on a truly international basis.

What has emerged is so huge that it cannot be referred to merely as a series of text-books. It is rather an encyclopædia of aeronautical knowledge and would be a valuable addition to most engineering libraries. Nevertheless, the very size of the work (each volume contains around 800 pages) and the large number of authors involved has meant that the publication has taken a very long time. It is noted, for example, that much of the material in the present volume was written almost ten years ago, and where it relates to performance data on actual engines is

therefore out of date. This would seem to be a failure of editorship. Either the book should have been brought up to date before publication or the obsolete material should have been omitted. It should be emphasized that this criticism may not apply with the same force to the previous volumes, which deal with the more fundamental and theoretical aspects of aeronautics.

Volume 12 is the last of the series, and deals with jet propulsion engines of all types, including rockets and reactor heat sources. It also includes some very valuable and useful information on the ground test facilities which are so necessary in the development of these types of engine. It is a very comprehensive and on the whole a well-written work.

In particular, the sections on solid- and liquid-fuelled rockets are small text-books in themselves, and will be excellent as introductions into a field which until recently has been almost entirely military and therefore to a large extent security classified.

The chapters on ram jets, ram-jet test facilities and on the use of atomic energy for jet propulsion are equally good and well presented, although suffering from the general criticism of being rather out of date in parts. Special mention must be made of the discussion on ram-jet control, which is excellent, presenting alternative methods and showing how difficult it is to sense truly representative internal pressures or velocities in closed loop systems.

The very width of the field covered has, however, meant a somewhat restricted treatment of many subjects. The volume sets out to be comprehensive, but it loses comprehension in a different sense by failing to take individual topics far enough. Many of the theoretical treatments have been so generalized as to necessitate over-simple assumptions and too perfect conditions. None the less, with this limitation, the treatments are well done, and, for example, would be useful to a flight vehicle engineer who wished to compare different methods of propulsion or to a propulsion engineer who wished to consider a different field of propulsion. The generalized treatment again could, with advantage, have been extended to cover adequately the overall performance of engine/flight vehicle combinations over complete flight patterns or trajectories.

A real weakness in the volume is the inadequacy of those parts dealing with the future of jet propulsion. Such subjects as flight in excess of Mach number 3, high-energy fuel combinations, vertical take-off engines are only touched on in the most superficial manner. Section L, which is entitled "Future Prospects of Jet Propulsion", consists of an interesting account of the morphological method of analysis which, however, fails to demonstrate how the most promising future lines of progress should be chosen. Indeed, some of the thinking in this section appears to be amorphous rather than morphological.

In conclusion, Volume 12 of the series is a considerable effort by a large number of distinguished scientists and engineers. Whether, turning to the preface, it succeeds in meeting "the long-felt want in Research Institutions, Universities and private industry" would be a matter of some doubt if the decision had to be taken on this volume alone. My opinion is that a full set of these volumes would be invaluable to those libraries which have sufficient aeronautical readers to justify the high cost.

W. CAWOOD

APPLICATION OF LAPLACE TRANSFORMS

Laplace Transforms for Electronic Engineers

By James G. Holbrook. (International Series of Monographs on Electronics and Instrumentation, Vol. 10.) Pp. xii+259. (London and New York: Pergamon Press, 1959.) 50s. net.

THE cult of manipulation without full understanding has achieved a degree of respectability since Oliver Heaviside made his remark about the necessity of eating even though the processes of digestion were not fully understood. He himself made full use of his own operational calculus without all the steps in it having been established with full mathematical rigour. It is indeed almost axiomatic that much progress in science and engineering is made by groping in the dark, and full understanding comes later, if at all. What is more controversial is whether it is desirable to teach the use of a technique, which is already fully and rigorously established, without, at the same time, explaining fully the steps on which the technique is based. The busy engineer, faced with the necessity of solving a particular problem quickly, may well feel justified in making use of the latest technique, without fully acquainting himself with the rigorous mathematics necessary to justify it. But should instruction of the student be based on the same principle of quick results? The mounting pressure of new subjects on an already crowded syllabus provides a great temptation to make the treatment of all subjects more superficial in order to introduce students to as many subjects as possible in the hope that a full understanding of the subjects of most use to him in later life will be acquired by detailed work after graduation.

Mr. Holbrook is in no doubt of the importance of a thorough study of the subject of Laplace transforms, and has the courage of his convictions to the extent of facing the possibility of this subject being excluded from the undergraduate course, rather than let it suffer from an unduly compressed course of instruction. He does not, however, insist on complete rigour, and there are places in his book where some additional rigour could be introduced with advantage, possibly by means of extended footnotes, which could be omitted during a first reading.

The first two chapters of the book deal with functions of a complex variable and the Fourier series and integral. These chapters might well prove difficult reading for a first study of Laplace transforms, but the advantage of this approach is very clearly seen in the third and following chapters, where the author establishes his transformations and transformation theorems with great ease.

The last half of the book is concerned with the application of Laplace transforms to circuit problems. Much of this is extremely interesting and valuable, but seems to lack the unity of presentation of the first half. Although the author deplores the reluctance of engineers to use nodal analysis and their fear of problems involving mutual inductance, mesh analysis is employed in most of the problems given in the book, and mutual inductance is not mentioned until the last quarter of the book where five pages are allowed for its treatment.

Apart from this lack of balance the book is most attractively written, and the arrangement of problems

in the text in preference to placing them at the end of each chapter, should encourage the student always to arm himself with pencil and paper when reading. The contrast between print and paper is restful to the eyes, but the diagrams are too small. Mistakes are few, and only on p. 140 would they be likely to mislead the student. The lay-out of the mathematics is good and there is a table of more than 200 transformations.

This book should be a useful addition to the library of many engineers and students.

A. H. M. ARNOLD

THE NUMBERS GAME

Electronic Computers

Principles and Applications. By T. E. Ivall. Second edition. Pp. viii+263 (32 plates). (London: Iliffe and Sons, Ltd.; New York: Philosophical Library, 1960.) 25s. net.

Computer Engineering

Edited by S. A. Lebedev. Translated from the Russian by Jane Stuart. Translation edited by J. P. Cleave and F. A. Sowan. Pp. vii+184. (London and New York: Pergamon Press, 1960.) 63s. net.

Analogue and Digital Computers

Introduction to Electronic Analog Computers

By Prof. John N. Warfield. (London: Prentice-Hall Electrical Engineering Series.) Pp. ix+175. (London: Prentice-Hall International, Inc., 1959.) 30s.

COMPUTERS are assuming an ever-increasing importance in the modern world. Having started as the plaything of the mathematician in the cloistered bowers of universities, they have successively penetrated into industry, commerce and, finally, they are likely to find a place in the government of nations. A measure of this increase in computer popularity is the almost exponential increase in the number of books on computers which have been and are being published.

A decade or so ago most authors started their book with a preface in which they explained why they had written the book, quite often couched in apologetic tones and usually with some cogent argument to justify their labours. Such literary politeness seems, however, to be a thing of the past and authors nowadays tend to give no reason to justify their effusions. In fact, a book may be justified on several counts. In the first place, novelty. The pioneers in a subject, if they have the time, can often write the first book which is available. Such books are useful in that they make available material which may only otherwise be found in the more esoteric literature. After this phase of development, the most likely reason for writing a book is that of popular exposition, since the original works may either be difficult intrinsically or alternatively have been succeeded by pedagogically better expositions and so have become unsuitable for teaching. In the case of the volumes under review, these two classes of book are represented and also the rather less desirable class of book, which presumably is written for no other reason than the desire of the author or publisher to 'get on the waggon'.

To deal first with the book by Ivall, this is in fact a second edition of the original book which appeared in 1956. The original work consisted of an edited version of a number of articles which appeared in *Wireless World*. The book has now been brought completely up to date, and something like a hundred pages of new material have been added. It is a book intended more for the wireless 'ham' rather than for the pure scientist or for the man in the street. There is a limited amount of technical material, but not enough, however, to build a computer, and too much to be intelligible to anyone who is not familiar with modern electronics. To the class of reader who is interested in electronics without being a specialist in computers the book can be recommended; to others, however, there are better things available.

Lebedev's book is in a different category. It is a translation of a Russian book which appeared in 1956, and deals with a number of aspects of computer design on an advanced technical basis. There is no concession to popular exposition, and the papers contained in the book are in the nature of a research collection. There is an account of the power supply for the Russian machine *BESM*, an analysis of digital differential analysers, an account of dynamic flip-flops and their use in computers, papers on automatic checking and on word selection from a dictionary (the latter based on a paper by me, which appeared in *Nature* in 1955) and two papers on matrix storage. For those Western workers in the computer field who do not read Russian, this book will be essential. Unfortunately, the price is high, considering the production, which is in lithographed, unjustified typescript; but even so, the good things in it make it well worth the money.

The collection of papers edited by Haley and Scott is, like the curate's egg, good in parts. There is an introduction to computing machines which did not appear to me to be particularly well written, three chapters dealing with the operation, application and design of analogue computing machines: these are excellent, although it is perhaps unfortunate that they are written by two separate authors with consequent breaks in style and gross overlapping. These are followed by an account of the way in which digital computing machines are operated. Part at least of this is a repetition of the first chapter, but considered as an introduction it is considerably more readable. The book ends with chapters on circuit elements for computers, on storage, on input-output equipment and on programming. The chapter on storage is dated and follows well-trodden lines, repeating several things from earlier books which have now been shown to be incorrect. That on input-output equipment is a reasoned and up-to-date account of what is available in this field, but the final chapter on programming is too short to be really worth while. This book is quite expensive for what it contains and the dichotomy of styles makes it somewhat difficult to read. It does not appear to add anything which will be of interest to the specialist, and, at the same time, is too advanced for the man in the street.

The book by Warfield has a somewhat misleading title, since, apart from a very brief introduction, in which a verbal account is given of the nature of digital and analogue computing machines, it contains nowhere any indication of the engineering details of an analogue computing machine. It is, in fact, a book which is primarily concerned with the programming of differential analysers. Considered as

such an account of programming it is one of the best books available on the subject. The techniques proposed are clearly set out and justified by sophisticated mathematics of a type which is not usually given in books on analogue computation. Apart from statements as to the way in which analogue computers are used, there is a set of appendixes which give the bibliographies of analogue computer elements and analogue computer applications. These are reasonably up to date, but suffer from the usual defect of American books in that they ignore all the literature published outside the United States. Rather surprisingly, the book ends with some suggested laboratory experiments. These will be useful to the growing body of departments which have analogue computers and have to instruct students in their use. The book is well produced and reasonably inexpensive. It can be recommended to those interested in this art.

A. D. BOOTH

INDIAN RESEARCH ON JUTE

Jute in India

A Monograph. By B. C. Kundu, K. C. Basak and P. B. Sarkar. Pp. xv+395 (47 plates). (Calcutta: Indian Central Jute Committee, 1959.) Rs. 30.

THIS book presents a most interesting and detailed account of the scientific and economic research work on jute carried out under the aegis of the Indian Central Jute Committee over the past twenty-five years. It is divided into three sections, the first being concerned with the botany, cultivation, and diseases and pests of jute, the second with the economic and marketing problems of jute growing, and the third describing the physical and chemical characteristics of the fibre, together with notes on the technology of jute manufacture.

The jute-manufacturing industries of the world consume nearly 2 million tons of fibre annually, virtually the whole of this being grown in the eastern States of India and in East Pakistan. Before partition of the sub-continent in 1947, jute was a monopoly crop for India; after partition, although India retained the jute mills, most of the fibre-growing regions went to Pakistan. In consequence, the jute-manufacturing countries outwith India now find themselves largely dependent on Pakistan for supplies of raw material, while India herself has striven to increase her acreage under jute sufficiently to maintain the volume of her production of jute manufactures independently. The book is solely concerned with the Indian aspect, but it is against this wider background that it will be read in Britain and Europe.

Commercial jute is a bast fibre obtained from the *capsularis* and *ohiorius* varieties of *Corchorus*. It is an annual crop, commonly followed by a crop of transplanted paddy, and in the first section of the book Dr. Kundu brings out very well the main factors of importance in growing and cultivation. All concerned with the production of jute, or indeed any bast fibre, will find much of value here. It is perhaps notable that the agricultural methods described are entirely manual, no power-driven machinery being employed.

Most jute growers are small-holders, and a considerable number share-croppers who pay a share of

the crop as rent of their plot of land. In section two Mr. Basak describes the economic studies which have been made into the circumstances of these small farmers, many of whom appear to live barely above subsistence-level. His comments and conclusions on the economic factors affecting the marketing of jute fibre must give food for thought to all concerned with the jute industry, and it is especially interesting to note the correlation between acreage under jute and the relative prices of jute and rice in the previous year.

The final section, by Dr. Sarkar, is somewhat condensed, and, although useful for reference, seems unrelated to the main theme of the preceding sections.

The book contains more than 400 references, the majority to Indian publications, and 75 photographs, one un-numbered and without legend. There are a few errors in the text, and throughout Indian weights and measures are used which may be unfamiliar to many readers. Unfortunately no index is provided, a serious omission in a work of this nature, which could serve as a useful reference book. These criticisms apart, however, the monograph is a welcome addition to the sparse literature relating to this fibre of world-wide usage.

H. P. STOUT

IN PURSUIT OF ANTIBIOTICS

Search for New Antibiotics

Problems and Perspectives. By Prof. G. F. Gause. (Trends in Science, Vol. 2.) Pp. x+97. (New Haven, Conn.: Yale University Press, 1960.) 4.75 dollars.

SINCE penicillin was developed as a commercial product there has been a feverish search for other antibiotics with similar or complementary properties. To-day, about a dozen antibiotics are in general use. Their discovery has been based on a purely empirical screening programme in which millions of potential antibiotic-producing organisms have been examined. Anything that could introduce a rational element into this search would be invaluable. Prof. Gause attempts to do this, and for this alone his book is worth study. His views are based on recent Russian research not too well known in Britain; it is useful to have an account of this work in English, and Prof. Gause is to be congratulated on the clarity of his exposition in a foreign language.

The author suggests that there are three principles by which the empirical search can be made more scientific. The first is concerned with the ecology of antibiotic-producers. He presents evidence that among fungi and spore-forming bacteria antibiotic-producers are more commonly found in warm soils than in cold northern soils. This could be a consequence of the richer microflora of tropical and sub-tropical soils. On the other hand, antagonistic Actinomyces seem to be equally common in soils from all latitudes. My impression is that at present it would be premature to concentrate too much on soils from one climatic region in the search for new antibiotic-producers. But with Prof. Gause's general conclusion, that further study of the ecology of antibiotic-producers may make the search more rational, I wholeheartedly agree.

His second principle is that a given species, or other appropriate taxonomic unit, 'tends' to produce the same antibiotics whenever it is isolated, and that in consequence, rapid identification of organisms can accelerate screening procedures, preventing to some extent the continual rediscovery of a known antibiotic. If such a procedure were used too rigidly of course new antibiotics might be missed. This principle would be most useful where fungi and bacteria are being screened; in the case of Actinomycetes, identification of the antibiotic produced may frequently be more certain and more rapid than identification of the producing organisms.

His third principle is that test organisms used in screening procedures should include some chosen to detect selective inhibition of specific biochemical mechanisms. Prof. Gause illustrates this by his own work at the Institute of Antibiotics, Moscow, using mutant bacteria and protozoa with impaired respiratory pathways. He considers that these are in some ways analogous to tumour cells, basing this view on the work of Otto Warburg, and therefore proposes the use of such mutants in screening for antibiotics with anti-tumour properties. It seems to me somewhat naive to base a search for anti-tumour substances on so simple a biochemical lesion in the test organism. Nevertheless, the data presented on their specific sensitivity to known tumour inhibitors are suggestive. But, whatever one may think of this particular instance, the general principle, that test-organisms with known biochemical lesions may be valuable in the search for antibiotics with specific properties, is undoubtedly valid.

In conclusion, though there is much in this book that is controversial, and much that one feels inclined to treat with reserve until more evidence is available, it is stimulating reading, and should be read by everyone interested in antibiotics.

P. W. BRIAN

DIPHENYLPROPYLAMINES AS ANALGESICS

Synthetic Analgesics

By Paul A. J. Janssen. Part 1: Diphenylpropylamines. (International Series of Monographs on Organic Chemistry, Vol. 3.) Pp. vii+183. (London and New York: Pergamon Press, 1960.) 45s. net.

THIS book is the third volume of the International Series of Monographs on Organic Chemistry, edited by D. H. R. Barton and W. von Doering. The series is intended to cover a wide variety of aspects of organic chemistry in the form of concise summaries containing all relevant literature references. It is with this premise in mind that the book should be read, since it deals with a rather specialized topic, namely, the role of diphenylpropylamines of the type:

in the analgesic field.

It is an astonishing fact that although the analgesic methadone, which possesses the diphenylpropylamine structure, was discovered by the original German workers in this field during the Second World War, an apparently unabated stream of related compounds displaying not only analgesic but also a wide variety of other pharmacological activities has been appearing ever since. It is against this background of intensive and prolonged research by Paul A. J. Janssen and many other workers in various countries that this book has been written.

The first two chapters are concerned with some ideas on the nature of analgesic activity and the relative potencies of four of the best-known analgesics. The next sixteen chapters each deal with the synthesis and properties of compounds with one variant of the group R and are rounded off by a chapter on a few less-important variants. There follows a small chapter on dissociation constants, which have been regarded as being of possible significance in the activity of such compounds. The book is completed by a brief treatment of the work of A. H. Beckett and his collaborators, who postulate that the absolute configuration of all analgesically active optical isomers is identical and related to the configuration of D-(-)-alanine.

A valuable feature of the book is a tabulated survey of physical properties and analgesic potency ratios, measured against a few well-known analgesics, of all the diphenylpropylamines reported in the literature. That the main tables cover about 100 of the 183 pages of the book gives some idea of the tremendous amount of work done in this field. Despite this, the author is frequently able to suggest further areas of research.

The accuracy of a book so full of facts requires much time to check, but spot checks and my personal knowledge of the subject revealed no gross deficiencies, either in subject-matter or literature references. There are a few minor errors. For example, on p. 111, during a discussion on preparative methods, there is some confusion of nomenclature, formula 7.4 on p. 123 has a vital bond missing, the description of the reaction sequence on p. 120 is confused by an incorrect formula reference, "amine" instead of "amide" appears at the beginning of Chapter 11, ref. 87 on p. 132 should be 88, and 'J. Org. Chem.' is omitted from ref. 317. However, in general, the errors are obvious and do not detract from the readability of the book. The correlation between the tabulated compounds and the structures discussed in individual chapters could possibly have been improved by the use of a common numbering system, but no great difficulty is involved on this score.

Dr. Janssen has written a thoughtful, analytical book which, although well confined to the subject-matter of the title, gives several glimpses of the many other pharmacological activities which modification of these propylamines produces. The reader may well detect a hint of the excitement which can be experienced during the investigation of structure-activity relationships in a successful line of research.

The book is recommended as being of value to the increasingly large number of those concerned with medicinal chemistry, as a concise method of following the work in this field. In addition, apart from its general interest, a number of chemically interesting points make it worth the attention of other chemists.

J. W. BILLINGHURST

The Great Barrier Reef and Adjacent Isles

By Keith Gillett and Frank McNeill. Pp. xiii+194 (161 plates). (Paddington, Sydney: Coral Press, Pty., Ltd., 1959.) 70s. (Australian).

TOURISTS with an interest in Nature will find all that they can desire in this book on the Great Barrier Reef of Australia by Keith Gillett and Frank McNeill. This is a first-class naturalist's guide book starting with a brief introductory account and taking the visitor first to the southerly Capricorn-Bunker group of islands. Then follow an account of the animals and plants to be found on land, an introduction to corals, and chapters devoted to molluscs, echinoderms, crustaceans, and other of the more striking reef inhabitants. This prepares the traveller for a journey farther north to the Cumberland group and other islands where a similar fauna will be found. An account is also given of Lord Howe Island and the Admiralty Islands.

There are other chapters on the resources of the reef, and the technique of underwater photography, together with practical hints for reef visitors. The book is well supplied with maps, and has good indexes to subjects and scientific names. It also includes mention of travel and tourists' facilities, including the underwater observatory at Green Island off Cairns. The interesting narrative is illustrated with superb photographs, many of which are in colour. The Great Barrier Reef is famous for the variety and splendour of its living organisms, and many of these are most beautifully portrayed. In fact, with this book the visitor can identify with certainty most of those animals which by their striking colour or form at once attract the naturalist's attention. The authors and publishers are to be congratulated on producing an authentic and beautiful handbook and guide, suitable for professional, as well as amateur, biologists, which will undoubtedly increase the enjoyment and value of a visit to the reef. It should also be in the library of those biologists not fortunate enough to go and see for themselves.

F. S. RUSSELL

Proceedings of the International Conference on Scientific Information, Washington, D.C.

November 16-21, 1958. Vol. 1: Pp. xxiv+1-812. Vol. 2: Pp. xii+813-1635. (Washington, D.C.: National Academy of Sciences-National Research Council, 1959.) 20 dollars the two volumes.

TEN years after the Royal Society Scientific Information Conference, the International Conference on Scientific Information, sponsored by the National Science Foundation, the National Research Council-National Academy of Sciences and the American Documentation Institute, was held in Washington in November 1958. All the Conference papers were issued as preprints to those who attended, but these are now re-published in two handsome volumes, together with additional material consisting of a memorandum to Dr. Alberto Thompson, who died before the Conference but who did so much towards its preparation, a preface by Dr. Wallace Atwood, jun., and the stimulating and scintillating opening address given by Sir Lindor Brown, one of the secretaries of the Royal Society. Moreover, the volumes contain the collected wisdom of the deliberations of the discussion panels and, in some instances, reports of the Conference discussions; there are also a list of those who attended and an index.

The papers cover the literature and reference needs of the scientist and their effectiveness, abstracting services, the organization of information services and storage and search systems, and the responsibilities of Governments and others in these fields. Some are verbose, some inconclusive, but there is much worth reading and pondering over. No rigid recommendations were made by the Conference, but, as Dr. Atwood remarked at the time, "'tis better to travel hopefully than to arrive". Scientific information bristles with complex problems, and while we travel hopefully towards their solution, the arrival of this important contribution to the literature is welcome.

C. A. RONAN

Lehrbuch der Physikalischen Chemie

Von Prof. John Eggert. Achte, neubearbeitete Auflage. Gemeinsam verfasst von Prof. John Eggert, Prof. Lothar Hock und Prof. Georg-Maria Schwab. Pp. xii+891. (Stuttgart: S. Hirzel Verlag, 1959.) 72 D.M.

THIS well-known book has been extensively revised and enlarged as compared with the English translation, and has to some extent lost its character as a readable elementary work and become a concise treatise on all branches of physical chemistry. Very recent work has been incorporated and there are abundant cross-references printed in the margins. References to literature are not given, apart from a list of books, mostly German and American, at the end, but the names of authors and the dates given will enable the publications to be traced in the abstract literature. The text is clearly and concisely written, and the mathematics is confined to elementary calculus. The sections on atomic physics and nuclear reactions are extensive, but the wave-mechanical theory of valency is only briefly treated. Experimental methods are dealt with concisely and there are many useful tables and graphs. As examples of modern topics the sections on low temperatures, semiconductors and reactions in solids may be mentioned. The chapters on photochemistry and colloids are good. The book covers all the branches of physical chemistry, and besides being a readable text-book it will be useful for reference purposes. The authors have evidently taken much trouble in the presentation of the material and the book will without doubt continue to be one of the best in its field.

J. R. PARTINGTON

Revision Notes on Biology for "O" Level of the G.C.E.

By G. T. Bolton. Pp. 17. (Oxford: Basil Blackwell, 1960.) 1s. 9d. net.

TO supplement existing text-books for the Ordinary Level examination in biology for the General Certificate of Education, G. T. Bolton, a biology master at Riton College, has prepared a set of notes which will be useful to all candidates in the twelve months before the examination. The notes include a number of lists and tables which the candidate can expand for himself into a full essay on the appropriate subject. The essential facts are briefly and boldly stated, but the notes can in no way be regarded as a substitute for a text-book. Some examination topics do not lend themselves to treatment in this way, and among the omissions are experiments which illustrate physiological processes in trees and plants throughout the year.

THE ROYAL SOCIETY

ANNIVERSARY ADDRESS*

By Sir CYRIL HINSHELWOOD, O.M., F.R.S.

AWARD OF MEDALS, 1960

Copley Medal: Sir Harold Jeffreys, F.R.S.

DURING the past forty-five years Sir Harold Jeffreys has carried out a long series of geophysical researches of fundamental importance. The problem of the internal constitution of the Earth involves many disciplines, and it was his outstanding achievement to take the existing scattered researches and weld them into the coherent subject now called the geophysics of the solid earth. His book, "The Earth", now in its fourth edition, is still the standard work in this field.

Jeffreys is best known as a theoretical seismologist. The Jeffreys travel-time tables, later revised in conjunction with K. E. Bullen, are not only the standard tables used in reductions of earthquake data but also are the basis of the best determinations of the elastic constants at all depths within the Earth.

He is the author of a number of papers on the radioactivity of rocks and the Earth's thermal history. Many years ago he emphasized the importance of making a deep boring through the ocean floor—a project which is now being undertaken by U.S. scientists. The interrelation of the phenomena of precession, nutation and the variation of latitude and the theory of the figure of the Earth led him to researches on these topics, and his analysis of gravity observations indicated a revision of the international formula for gravity, with a corresponding revised estimate of the Earth's ellipticity. The figures of the Earth and Moon formed the subject of his first paper in 1915, and in 1948 he gave a very important discussion of the general adjustment of the data relevant to the radius and ellipticity of the Earth, the lunar parallax and the moments of inertia of the Moon.

Jeffreys has carried out many researches in dynamical meteorology, and his classification of winds and his theory of monsoons are incorporated in the standard works on the subject. He extended the classical theory of the tides to atmospheric motions, and his work on the generation of water-waves by wind has led to many later developments.

His writings on the theory of probability and on scientific inference, his work on the asymptotic solution of differential equations and his systematic treatment of the Heaviside operational calculus have proved valuable. His continued interest in the problems of structural geology has helped markedly to close the gap that formerly existed between geology and geophysics.

Rumford Medal: Dr. A. G. Gaydon, F.R.S.

Dr. Gaydon is distinguished by his work in spectroscopy and particularly molecular spectroscopy. One of his main fields of research has been in the applica-

tion of spectroscopic techniques to the study of flame phenomena. His studies of low-pressure flames, development of the nitric oxide test for atomic oxygen, measurements of rotational temperatures and discovery, with H. C. Wolfhard, of abnormal electronic excitation in the reaction zone, contributed much to knowledge of the processes occurring in combustion. Similar techniques have recently been applied to shock waves, and the shock tube has been developed into a tool for studying times of relaxation of molecular vibrations and dissociation.

Another main field of his interest has been the determination of the dissociation energies of diatomic molecules, and his book "Dissociation Energies and Spectra of Diatomic Molecules" is a standard monograph on the subject.

Gaydon has made many contributions in other branches of molecular spectroscopy as in the discovery of new band systems (for example, the ultra-violet ${}^1\Pi_u-{}^1\Pi_g$ bands in N_2), the investigation of predissociation and laboratory observations of spectra similar to that of the night air glow.

Gaydon has also published "The Identification of Molecular Spectra" (with R. W. B. Pearse); "Spectroscopy and Combustion Theory"; "Flames, their Structure, Radiation and Temperatures" (with H. G. Wolfhard), and "The Spectroscopy of Flames". All these are distinguished works of much value and importance.

A Royal Medal: Prof. A. C. B. Lovell, O.B.E., F.R.S.

Much of our present knowledge of radio astronomy is due to Lovell's insight, initiative and originality. With his colleagues he has made contributions to our understanding of meteor astronomy and of 'discrete sources', and the conception and present achievements of the large radio telescope are largely due to his efforts. From visual observations it has long been known that meteors fall into two main classes. Shower meteors are clearly members of the solar system, but until the work of Lovell it was generally believed that the so-called sporadic meteors had velocities in excess of parabolic and were intruders from outer space. Lovell has been able to show conclusively that these objects too are members of the solar system, and further to show that the diurnal and seasonal variation in their numbers is consistent with such an origin. By his published works he has established the whole subject on a new and firm foundation.

Lovell and his colleagues have studied galactic radiation in the metre range. Fluctuations in this emission from certain constellations had suggested the occurrence of 'discrete sources'. Lovell was able to show that the fluctuations originate in disturbed regions of the ionosphere. It was found that the sources had diameters of a few minutes of arc, and thus

* Delivered at the Royal Society on November 30.

shown that the radiation did not originate in stars. Further work by Lovell's group showed that some of the discrete sources lie outside the galactic system, and that there is a roughly spherical halo well outside the visual system.

The conception and design of the large steerable paraboloid telescope are due to Lovell. Its construction represents the most significant advance in radio astronomy, and other larger instruments being built in different parts of the world are based upon it. It has proved invaluable for the tracking of stellar objects, but promises already to reveal much more about galactic radiation. Work on the 21-cm. hydrogen line is already providing much valuable information about the structure of the galactic system.

A Royal Medal: Sir Roy Cameron, F.R.S.

Sir Roy Cameron's chief interest over many years has been the mechanism of cellular damage by various agents and the response of the damaged tissue towards restoration of normal structure and function. His early work analysed the pathology of liver disease by resolving it into simple components related to the vascular system and to the excretory apparatus of the organ. This led on to a series of researches into the actions of various poisons which selectively destroy liver cells. His elegant study of the prolonged action of the chlorinated hydrocarbons provided experimental proof of the 'reversibility principle' in chronic liver disease, an achievement which has changed our outlook on some of the degenerative diseases which were once regarded as hopeless.

Cameron's investigations of body fluid redistributions in disease have added much to our knowledge of the causes of shock and of the pathogenesis of oedema of the lungs. He was the first to produce a neurogenic lung oedema, a discovery which helped to explain certain clinical phenomena that had long baffled surgeons. His war-time studies of arsenical and other poisons revealed unexpected modes of disease production and supplied a key for effective prevention and treatment. He has made important contributions to our knowledge of the mechanisms by which under-water explosions produce pathological effects, the practical result of which has been improved methods of care and treatment of men injured during diving and exposure to depth charges.

Cameron has built up a lively school of cellular pathology which has undertaken the critical re-examination of many of the classical notions about cellular disturbances and thus reorientated the outlook on diseases to which such disturbances give rise. He is recognized throughout the world as one of the foremost of living pathologists and has contributed much to revitalize British pathology by ingenious applications of the experimental method in problems of human ailments.

Davy Medal: Prof. J. M. Robertson, F.R.S.

When X-ray diffraction by crystals was first discovered nearly fifty years ago, it was a problem in optics and as such was studied almost exclusively by physicists. W. H. Bragg realized that since the compounds to be investigated would become increasingly complex, it would be advisable to have an organic chemist in his team of research workers. He therefore invited John Monteath Robertson to work at the Royal Institution; and the distinction of the research work he did fully justified that choice.

J. M. Robertson proved to have just the qualities needed for the field of crystal structure analysis by diffraction techniques. Using the two-crystal moving-film spectrometer, and numerical and mechanical methods of Fourier analysis that he himself devised, he was not only the first to make a systematic investigation of the structures of such simple organic molecules as anthracene, naphthalene, durene and *p*-benzoquinone but also was a pioneer in the study of polymorphic structures (α - and β -resorcinol), *cis*- and *trans*-isomers (azobenzene), series such as dibenzyl, stilbene, tolane, involving bonds of varying order, or such as oxalic acid dihydrate, acetylene- and diacetylene-dicarboxylic acid dihydrates, where the existence of structural isomorphism is disguised by changes of unit-cell shape. He developed the 'heavy-atom' and 'isomorphous-series' techniques and used them to obtain the formulae, stereochemistry and structure of the phthalocyanines, and later of cupric tropolone, the polysulphides and sulphonyl sulphides. He used structural data for the determination of molecular weights and (with others) investigated the effect of isotopic substitution and of thermal expansion in structures containing hydrogen bonds. His later studies of large condensed aromatic molecules and of compounds where steric hindrance forces an aromatic molecule to lose its planarity have provided valuable data for theoretical consideration.

Darwin Medal: Mr. E. J. H. Corner, F.R.S.

E. J. H. Corner first showed himself to be outstanding by his work in collecting and identifying toadstools. At the same time he developed a strong conviction about the advantage of studying plants in the wet tropics. In pursuance of this idea, he went to Singapore, where he worked for a good many years (including the period of Japanese occupation), and later worked in Brazil. The climax of his interest in toadstools was marked by his monograph on the great and exceedingly difficult group *Clavaria*. He found that he could recognize different systems of basic architecture in the growing tissues, and with this in mind he was able to organize what had seemed chaos into orderly sections.

His work on the huge fig genus, its classification, distribution and probable evolution represents work, on orthodox lines, but his studies on the evolution of tropical plants in general culminated in his celebrated 'Durian theory', which is still developing and may be deemed a major contribution to botanical thought.

This theory deals with the probable course of plant evolution in tropical high forest from remote periods down to the present time. He assumes that the main stream of plant evolution flowed in this environment, and then considers how the special features of this environment would favour particular kinds of plant organization. He concludes that the durian tree of Indo-Malaya represents the archetype of tropical forest tree—with its thick stem, large leaf, large seed, edible aril and other characters.

The Durian theory met with opposition, but is now widely referred to with respect.

Hughes Medal: Dr. J. L. Pawsey, F.R.S.

Dr. Pawsey is acknowledged as one of the pioneers in the development of radio astronomy. Soon after the War the Commonwealth Scientific and Industrial

Research Organization established a division of the Radio Physics Laboratory at Sydney, Australia, to carry out research work in radio astronomy, and Pawsey became the head of this division. Apart from many major personal contributions Pawsey has inspired a great variety of other fruitful investigations.

The Radio Physics Laboratory has carried out extensive work in both solar and galactic radio astronomy. At an early stage the principle of the Lloyd mirror was used to devise a radio-interferometer, the surface of the sea being used as the mirror. With this new device, some of the earliest evidence of the existence of the direct radio sources, radio stars, was obtained, and extensive studies of solar radio emissions carried out. Later, much more elaborate new interferometers with greatly increased resolving power were developed. The results are important for the understanding of solar terrestrial relations and include evidence of ejection of matter from the Sun during a period of intense radio emission.

Pawsey and his colleagues also continued the study of the galactic radio sources. By improved resolution they were able to identify some of the 'discrete sources'. Soon after the initial discovery of the emission of the 21-cm. hydrogen line, the laboratory began a detailed survey of the distribution of neutral hydrogen throughout the Galaxy, so far as could be undertaken in the southern hemisphere. Together with the work of Oort in Holland, the results have established the spiral character of our Galaxy. It was also soon established that the hydrogen line was emitted from an extragalactic object—the clouds of Magellan.

In addition to playing the leading part in these investigations, Pawsey has always maintained an interest in ionospheric studies and made an important contribution to knowledge of the lower fringes of the *D* region by carrying out reflexion sounding from a site in New South Wales, where the background noise was exceptionally small.

Pawsey, in conjunction with Bracewell, has written a standard monograph on radio astronomy.

OBSERVATIONS ON CELL MECHANISMS

It is five years ago to-day that I assumed the office which within an hour I shall be handing over. The intervening years have proved eventful ones in the life of the Royal Society. The Antarctic Expedition sailed to Halley Bay, made its distinguished contribution to the International Geophysical Year and returned, having written one more chapter in the Society's proud record of scientific exploration. Yet another chapter has been added by a biological expedition to one of the most interesting regions of South America. Although the future in this field is uncertain, progress has been made in the planning of space research in Britain.

When infused with true vitality, tradition is indistinguishable from progress, a truth which is apparent in many of the affairs of the Royal Society, and in none more than in our relations with our colleagues abroad. The historic friendship with American men of science, unbroken since the days of Benjamin Franklin, was movingly demonstrated by the National Academy of Sciences when it devoted one of its most important annual occasions to the honouring of the Royal Society Tercentenary and in the most cordial way invited your President to take

part. Regular exchanges of students and lecturers with the Soviet Union have been brought into operation by agreements with the U.S.S.R. Academy of Sciences. I am specially happy to record that relations with the Academia Sinica, initiated last year by my own visit to China at their invitation, are developing in an encouraging way.

The whole field of international relations has been extraordinarily active, and I want to pay just tribute to the retiring Foreign Secretary, Sir Gerard Thornton, who has throughout so admirably performed the ever-growing duties of his office.

A practical body like the Royal Society is always conscious of the problem of ways and means. The Tercentenary Appeal and the establishment of the Wolfson Research Professorship have increased the resources with which the Society can meet its many obligations. If to-day we face the future with very substantially improved prospects, it is due to the energy and the vision of Sir William Penney, who retires to-day from the office of Treasurer, leaving the Society lastingly indebted to him.

The Tercentenary Celebrations are fresh in the minds of us all and I shall not recapitulate the many thoughts about the past and the future which were then expressed. But there is one thing which must be said, and that is to record gratitude to all who toiled so hard to make the events of the summer a success, and above all to Dr. Martin and his staff; and as far as I am concerned I must express my indebtedness not only in respect of last summer but of my whole term of office.

We have now returned to the workaday world of the new century, when we do well to remember again that the great themes of science emerge only after the accumulation of the results of many patient labours. I shall revert to some of those details now, and devote the rest of this address to some recent work on the biophysics of living cells which I have been able to follow at close quarters.

It has sometimes seemed to me that many people speak too much as though little mattered in living cells beyond the code inscribed in their nucleic acids, the mechanism of expression of this code in the cell properties being a relatively trivial affair. A change in the code is a mutation, and a convenient simplification ascribes all adaptive responses to mutations, ignoring the latitude which may exist in the translation of the code. But the detailed study of cells shows that there is in fact very much latitude. To quote one example, my close colleague A. C. R. Dean has recently studied the proportions of RNA, DNA and bacterial protein in cells grown under varied conditions. They vary widely, as does the cell size. There are clear evidences of oscillatory or 'overshoot' phenomena, suggesting a subtle and adjustable balance of interacting systems in mutual dependence. With change of medium the proportions of various enzymes in bacteria change very considerably, and enzymes are of course necessary for the synthesis of nucleic acid components.

The code-pattern of the DNA determines the cytoplasmic make-up. But, unless a non-physical kind of influence is assumed, Newton's Third Law suggests that in principle the cytoplasmic constitution might influence the DNA pattern itself. In other words, mutations normally attributed to accident might be induced, though this back action might be quantitatively small. In the synthesis of DNA the code must be spelled out in some polycondensation reaction.

At any stage of this process the alternative addition of a monomeric unit X or Y is believed to depend on what are essentially steric conditions. Yet these define a probability, not a certainty, and the normal course of addition could be modified by mass action factors coming into play if the changed cytoplasmic organization changes the proportions in which the monomeric units are offered to the growing points of polymers.

Thus there are several ways for unicellular organisms to respond to changed environment: quantitative readjustments in the proportions of cell components, gradually induced changes in the DNA code, and, as commonly assumed, selection of mutants formed by chance errors in the code and ousting the original forms by growing faster or surviving longer.

It has been widely asserted that the simple selection of chance mutants is the only true mechanism of adaptation. This view may have been based on an exaggerated view of what natural selection can account for, on some misrepresentation of Lamarck and on the failure of experiments on the so-called inheritance of 'acquired characters'. Perhaps also the unmistakable evidence that natural selection has operated has masked the fact that the variations selected may have had many kinds of origin and that there is no exclusive virtue in chance.

Not all biologists indeed adopt this attitude. T. M. Sonneborn, for example, discussing cell differentiation, remarks: "There is thus in general a marvelous system of give and take among certain genes and the cytoplasm" and he refers to "successive cycles of differentiation of cytoplasm by nucleus and then of nucleus by cytoplasm".

Experiments with unicellular organisms continue to show how manifold, subtle and unexpected are the phenomena of growth and adaptation, and fail to countenance the view that mistakes in coding are the sole source of advantageous variation.

Some years ago Akiba and afterwards Szybalski reported that cells in bacterial suspensions exposed to streptomycin were found after a time to be all dead or all resistant. This result was later re-interpreted by the idea that sensitive cells underwent lysis and were replaced by pre-existent mutant types which multiply on the debris. Similar objections were raised against F. J. Ryan's experiments on cells of *Escherichia coli*, which originally required histidine for growth but which on storage in a medium deficient in histidine gradually acquired the property of histidine-independence. Ryan, however, demonstrated that lysis and re-synthesis did not in fact occur. The proof consisted in showing that, in a medium containing lactose, the predicted shifts in the proportions of (histidine)- (lactose)⁺ and (histidine)- (lactose)⁻ are not observed as they should be if cryptic growth is the explanation. Ryan thinks that the DNA pattern changes during the stationary phase by some process other than a mistake in replication during growth.

Further light on the course of an adaptive phenomenon is thrown by the experiments of Midgley on the utilization of D-arabinose, and of N. Richards on the utilization of lactose by *Bact. lactis aerogenes*. The bacterium when first offered D-arabinose as sole source of carbon begins to multiply only after a lag of some days, which represents, according to one view, the time needed for internal adjustments in all the cells, and, according to another view, time needed for the multiplication, to the threshold of detectability,

of a very minute proportion of abnormally coded mutants. Arguments, counter arguments and rejoinders beset this apparently simple theme. The new evidence is as follows. At various stages of the adaptation, enzyme activity tests (relevant to the utilization of D-arabinose) are made on unit mass of the culture. The measured chemical activity can, as a purely arithmetical operation, be divided either by the total mass of bacteria, or by the actual increase in mass since the adaptation started. In the first case the resulting quantity rises gradually and naturally to a limit as the exposure to the sugar continues and growth sets in. In the second case, which is appropriate to show the properties of the hypothetical mutants, the specific activity shows a most improbable course. Soon after the onset of growth it rises sharply to a very pronounced maximum from which it then rapidly falls again. The maximum is very much higher than is ever again found, even with the most thoroughly adapted cells. The mutants apparently acquire, just at the moment when they happen to be outnumbering the original non-mutants, a momentary activity far greater than they ever show again in the whole course of their history. If the idea of special mutants is abandoned, this strange behaviour is explained away by the simple fact that the chemical activity has been divided by the wrong quantity, not, correctly, by the total mass, but, incorrectly, by the increase in mass.

The subsequent history of the adaptive enzyme changes during prolonged cultivation in D-arabinose, and during alternate periods in arabinose and glucose reveals an intricate pattern of successive reorganizations. At first the arabinose-utilizing enzymes prove unstable to growth in absence of arabinose, and decline. But with longer adaptation to arabinose they do this less and less, and in a way which shows the whole conception of 'stable heredity' in adaptive changes to be complex and relative. According to the precise conditions of growth, the special enzyme may either decline or continue to be synthesized in the absence of the original 'inducer'.

All these facts give a powerful impression of a machine with intricately geared parts, of equilibria and quantitative balances about which by no means the last thing can be said in terms of mistakes in coding.

Cannon has complained of the confusion caused by mistranslation of Lamarck's word 'besoin'. This should of course be translated 'need', and, without entering into more controversial fields, I should like to point out that in adaptive studies the development of functions in response to needs is very much in evidence. For example, N. Richards, in his studies of lactose utilization, finds that as a culture of *Bact. lactis aerogenes* becomes short of oxygen the galactosidase activity increases. In the absence of oxygen, utilization of carbohydrate is less efficient: more is needed, and more is made available by the increase in enzyme activity. This is clearly a response to a 'need'. It is not mysterious. When the enzyme is insufficient, processes dependent on it are retarded relatively to its own synthesis, with the result that its proportion increases until a proper balance is established.

It is a quite general law for the reproduction of living matter that the reaction system tends to be established which gives the greatest growth-rate. This, it is worth while pointing out once more, is itself a form of natural selection, automatically operating to

favour the predominance of the most efficient systems. In the long run the selection of the best reaction pattern gives the same result as the selection of a special type of individual.

The orthodox view, however, is that such phenomena are of little significance beyond the generation in which they occur. On this several things may be said. Cannon has objected that most of the negative experiments on acquired character transmission have been of a rather crude kind, in which failure proves little or nothing. There is no doubt that the persistence of adaptive enzyme formation through many cell generations in the absence of the inducing agent is a very variable and complex story. The persistence may be great even where the evidence suggests that the original adaptation was not a mutation.

There are perfectly natural physicochemical mechanisms by which a changed cell organization could survive for many divisions of a unicellular organism returned to a previous habitat after an adaptive interlude. But, in addition to this, Newton's Third Law, as I have already said, discourages belief in the absolute inability of genetic codes themselves to be modified by the workings of the very systems which are built to their instructions, and by which, be it said, they themselves have to be reproduced. The gradual stabilization of adaptations is a very striking phenomenon, upon which I think we should ponder deeply. In his book "Brain, Memory and Learning", W. Ritchie Russell says, "All living matter shows features that may be considered a form of memory. It all shows spontaneous activities that tend to form patterns which are at first relatively simple, but show a strong tendency to repeat".

An interesting variation on the theme of stabilization is reported by Ierusalimski. A spore-forming organism (*Clostridium acetobutylicum*) was adapted in continuous culture for 21 days to resist the toxic action of 0.6 per cent butanol. After sporulation, the strain was no more resistant than a control. When, however, the adaptive treatment had been further prolonged and the butanol concentration gradually increased, the resistance not only rose but also could now survive passage through the spore form.

I shall now turn briefly to some of our own results on the resistance of micro-organisms to drugs, and will begin by repeating my belief that not one but several mechanisms exist for this phenomenon, and, in particular, that accidents of code replication are not the sole or even necessarily the most important source of resistance.

To find the proportion of resistant mutants a common method is to spread a very large number, N_0 , of organisms on an agar plate with nutrient and with the drug at concentration c and to count the number, N_∞ , of colonies that eventually develop. $N_\infty/N_0 = \alpha_\infty$ is the required proportion. More detailed investigation alters the picture. The colonies take different times to reach a standard size, and the proportion, α_t , rises with time from zero to α_∞ according to a curve indicating an approximately Gaussian distribution of development times. J. B. Woof has studied the phenomenon with *Bact. lactis aerogenes* and chloramphenicol. As the drug concentration increases, L' , the time at which $\alpha_t/\alpha_\infty = 0.5$, decreases, a rather paradoxical behaviour for mutants. With an adaptive hypothesis the paradox disappears. α_0 is small because there is a race between adaptive adjustments and lethal processes which, given time, stop the cells from forming colonies

at all. Calculation shows that if the logarithmic death-rate is λ , L' will in fact decrease as λ increases, that is as the drug becomes more potent. If the cells die quickly only those that make haste to adapt ever have a chance to form colonies at all. The successful ones are those in the tail of the statistical distribution. The fiercer the drug action the more the colony formation is confined to the exceptional members of the distribution. Woof's studies show that this picture works out quantitatively.

The conception of adaptive and lethal processes in competition may be thought difficult. The reality of such superpositions of conflicting processes is illustrated by some of Midgley's experiments on the adaptation of *Bact. lactis aerogenes* to D-arabinose. At the initial transfer to the pentose the lag is x days and the subsequent growth-rate r_1 , which is far below the optimum. If the lag in arabinose is interrupted by passages in glucose during which growth takes place, the total value of all the lags in arabinose before growth occurs in it still adds up nearly to x . But, as a result of the intermissions for growth in glucose, the growth-rate in the arabinose is now much greater than r_1 . During the long adaptation to arabinose other cell mechanisms suffer from ageing unless they are kept mobilized by the opportunity for use in the glucose medium.

In the competition of adaptive and lethal processes the situation might perhaps be likened to that of a man dying of destitution while he is struggling to finish a job which will furnish the means for his physical salvation.

Another approach to the problem of chloramphenicol-resistant colonies has been followed by Dean. If the drug concentration on an agar plate is low enough, every cell plated can form a colony. An inoculum from one of these colonies is spread on a plate with a slightly higher concentration of drug, and again the proportion forming colonies approaches unity. Proceeding carefully in this way, and sometimes spreading for several successive tests at the same drug concentration, we can arrive at colonies growing on plates with ten or twenty times the concentration which would originally have been completely inhibitory. At every stage of the process the yield is so high as to rule out all possible talk of rare mutants. Errors of coding which can occur every time, or even once in two or three times, would seem to be misnamed.

The most powerful proof that resistant forms can sometimes arise fortuitously comes from Lederberg's elegant technique of 'replica plating'. The principle, briefly, is that, by means of a suitable pad, multiple prints can be made from a given bacterial plate on to several others, with and without drug. Resistant colonies can be detected on the drug plates, and their opposite numbers on the drug-free plates isolated. By successive enrichment resistant strains can be obtained without previous direct contact with drug.

Lederberg obtained in this way strains resistant to streptomycin and to bacteriophage. By a modified replication technique Cavalli, however, could obtain only a small increase in chloramphenicol resistance comparable with what can occur as a result of varied cultural history. It seems, nevertheless, to be tacitly assumed sometimes that the replica plating technique can be quoted to prove the existence of mutants in cases to which it has not been applied at all. This is particularly inadmissible because both phage resistance and streptomycin resistance can arise from

damage, for example, by ultra-violet light, depriving the cells of receptors for the agents in question.

It has also been pointed out that the organisms isolated by replica plating are never known to be resistant until they have been tested in the presence of a drug. What has been selected, therefore, may be not so much a resistant form as one specially endowed with the power of responding rapidly when exposed to the drug, that is of doing what in other examples a large proportion of the population succeed in doing more slowly. This reflexion suggests the possibility that the differences in behaviour are not necessarily more than quantitative. Valuable information may thus be forthcoming from a more detailed study of the response to drugs of organisms selected by indirect means.

Discrepancies in apparent results often arise from unsuspected differences in method. It is therefore of interest to note that W. T. Drabble, by the same methods which have provided evidence for direct adaptation to chloramphenicol and other agents, has obtained results with streptomycin pointing clearly to the presence of some initially resistant forms of *Bact. lactis aerogenes*. There are also indications, which he will report in due course, of a superposition of direct adaptation upon a selective process.

In this last address from the presidential chair I have, as it were, returned to the laboratory by a deliberate choice. It was not that large general themes, scientific or otherwise, were lacking. I had perhaps reflected a little on a remark I heard recently from a young colleague to the effect that scientists tended to deal with broader questions when they were getting past work in their own field, but I am, I think, on good enough terms with my younger colleagues not to be intimidated by them. It was rather that, after the Tercentenary, it seemed better to strike the workaday note once more. Some of the views I have

expressed may seem to verge on the heretical. They are not, I think, irreconcilably so. In a recent study which Bartlett and I made on the crossing of resistant and non-resistant bacteria, we reached some conclusions which at any rate one colleague in genetics welcomed as support for an orthodox view. The truth, I believe, is that we need a re-synthesis of some of the widely accepted views with the kind of approach that appeals more to the chemist and the physicist.

Be that as it may, nobody would expect an occupant of this chair to subscribe against his beliefs to orthodoxy. May I quote once more the words of Horace with which you are familiar:

"ac ne forte roges quo me duce quo lare tuter
nullius addictus iurare in verba magistri"

I hope the President himself may be forgiven for following this example.

To have been President of the Royal Society is, it seems to me, the greatest honour which any man can have received, and one of which no man can feel he has been worthy. For myself I can only thank those who have done their best to see me through. I welcome my successor and wish him well. There are plenty of problems ahead. For example, our long and, though informal, immensely important relations with the Government are in process of adaptation to the vast scale and complexity of scientific activity to-day. The optimum solution of this problem is of the greatest importance both to the Society and to the country. Of equal importance is the establishment among the Fellows of the right balance between the pure and the applied sciences to enable the Royal Society to maintain its full influence in the modern world.

I regard the future of the Society with confidence not least because I see no sign that it is likely to depart from the principle declared in its motto that it will remain "nullius in verba".

TREND OF CAESIUM-137 IN THE EFFLUENT OF A LARGE CITY*

By DR. T. R. FOLSOM

Scripps Institution of Oceanography, La Jolla, California

AND

DR. G. J. MOHANRAO

California Institute of Technology, Pasadena, California

THE oceanographer is concerned with the mechanisms controlling the dispersion of materials in the ocean. For this reason, the progress of fall-out radioactivity in the ocean has been studied for several years at the Scripps Institution; recently special consideration has been given to contributions coming from terrestrial run-off. Several radioactivities in sewage flowing from a large coastal city were monitored at the treatment plant for more than two years. Caesium-137 was followed in detail; this fission product has useful tagging properties; it emits a

penetrating, easily detectable γ -ray, and decays relatively slowly.

Detailed off-shore mapping has not yet been done; however, the average and peak outputs from the city have been recorded over a period of 21 months, permitting estimates of the influence on coastal waters. The character and trend of the concentration, and comparisons with reported contamination of human food by fall-out, point to an unexpected source for the caesium-137 observed in the sewage. Not a great deal is known about the chemical behaviour of this nuclide, at very low concentrations and in complex systems, so that the partition observed for caesium in the plant should be of general interest.

* Substance of a paper read in part at the meeting of the International Association of Physical Oceanography, Helsinki, Finland, on August 5 1960.

We were fortunate in being permitted to make measurements throughout the Hyperion Treatment Plant of the City of Los Angeles. This modern installation is situated on the seashore 120 miles north of the Scripps Institution; it collects sanitary sewage from a large city centred about 30 miles inland; and disposes the treated material mainly through outfall pipes extending as far as 7 miles into the open sea where the depth is about 200 ft. Very little storm water enters this system.

For about ten years, until June 1, 1960, the treatment included primary settling, aeration with activated sludge, final settling, digestion of primary and activated sludge, followed by the filtering, washing and drying of part of the digested solids to produce a stable dry fertilizer that was sold as soil conditioner. After this date a change was made in the treatment schema, so that routine drying of large amounts of fertilizer was stopped.

Investigation at the plant consisted of: (1) sampling continuously and in detail at one point in the system; (2) sampling also at several points during a given short period, preferably when the input character was not changing rapidly. While it was available, the commercial fertilizer was used in the continuous monitoring; it was convenient, and because caesium is greatly enriched by treatment up to this point, extremely small changes in input concentration could be deduced. These samples were assayed after being composited daily for periods of 3-5 days. Most of the other specimens used for establishing partition ratios were liquids, some of them very dilute. All were reduced to dryness at the plant in 40-gallon soup kettles heated with steam.

Assaying was done at the Scripps Institution by exposure of a sodium iodide scintillator crystal to the radiation from a relatively large specimen, one weighing about 200-400 grams. With a modern multichannel gamma-ray spectrometer a specimen may be analysed within a few minutes for one or more gamma-emitting nuclides, even when their concentrations are very low. Usually no wet preparation whatever was undertaken; however, specimens were assayed in plastic containers under uniform conditions, so that accurate comparisons with standard specimens could be made. The laboratory at Scripps had already developed a spectrometer accessory¹ permitting the rapid comparison of measurements with a library of background measurements and measurements of standard specimens all stored in digital form on magnetic tape loops.

In passing, it will be mentioned that the sewage had less radioactivity than was anticipated; no concentration was observed even approaching a recognized tolerance-level. Nevertheless, the natural background from the uranium and thorium families almost always was surpassed by one or more man-made activities. Iodine-131 appeared in nearly every input specimen as might be expected from its use in medicine; cobalt-60 repeatedly appeared in easily measurable amounts. Relative to the concentration

Fig. 1. Trend of caesium-137 in the sewage treatment plant compared with the trend in milk. All ordinates are microcuries per gm. of dried solids. Inset illustrates that batch inputs probably contributed little during comparisons early in 1960

of caesium-137, the concentrations of both zirconium-95 and ruthenium-106 were extremely deficient when compared with the ratios observed in rainfall for this period. Details concerning these and other activities will be reported elsewhere.

Monitoring radiocaesium in digested material has several practical advantages; but because of the long dwell of material in digesters, the information is not contemporary, and some input detail is lost entirely. Fig. 1 shows the trend of caesium-137 concentration over 21 months derived from 75 composited samples of digested fertilizer. The large peaks attenuate at a rate consistent with what is known about the purging-rate of these digesters. Actually a battery of digester units is used at Hyperion; nevertheless, their performance might be approximated roughly by a model having a single tank into which a daily input is suddenly injected and mixed thoroughly followed by the withdrawal of an equal amount, about one-thirtieth of the whole. It can be shown that this model would purge itself after a sudden excessive input to half-peak-concentration in about 21 days. The actual measured initial slopes of the two larger peaks correspond to a half-purging time T' of about 17 days.

In spite of the large batch inputs, it appears from Fig. 1 that the input concentration varies only slowly much of the time and follows an easily measurable basic trend. It required roughly four months for attenuation of the largest batch, but ultimately this reached insignificance. An inset is shown in Fig. 1 magnifying the data for the first three months of 1960, and an exponential curve having half-value of 17 days has been added to it to illustrate that the largest peak and later smaller ones probably have become greatly attenuated during the period when input concentrations were compared with average concentrations in the digested material. These comparative measurements are plotted in the inset of Fig. 1 and listed in Table 1. From these roughly steady-state conditions we can derive ratios that should approximate fixed characteristics of the plant. Table 1 indicates that the incoming caesium-137 is enriched after digestion by a factor of about 1.4/0.32 or 4.4 (on a dry basis).

It can be concluded from these measurements that the concentration of caesium-137 in the sewage coming

Table 1. COMPARISON OF INFLUENT AND FERTILIZER CONCENTRATIONS

Collection date of composite sample (5-day period ending)	Concentration of ^{137}Cs ($\mu\text{c. per gm., dry}$)
Dry fertilizer (after long digestion)	
January 27, 1960	1.2
February 2	1.4
" 10	1.8
" 17	1.5
" 24	1.6
March 2	0.7
" 9	1.8
Fertilizer average	1.4
Influent (composited 5 days and dried)	
January 6, 1960	0.39
" 15	0.22
" 22	0.48
" 29	0.19
February 12	0.32
Influent average	0.32

into the plant fell slowly over 21 months from about 1.1 to about 0.32 $\mu\text{c. per dry gram}$; this corresponds to a change from 1.4 to 0.4 $\mu\text{c. per litre}$.

Now it can be appreciated why direct monitoring was not carried out. No satisfactory chemical precipitation had been developed; boiling down all specimens in barrel-sized amounts would have been expensive; and the spectacular enrichment in the digested material was attractive. For example, raw sewage having 0.4 $\mu\text{c. per litre}$ of caesium-137 produces dried fertilizer having 1,400 $\mu\text{c. per dry kgm.}$

Obviously the large peaks in Fig. 1 arose from batch inputs. But no technical or medical practice has been discovered that would explain the slowly varying basic concentration-level. When measurements were made of representative samples from the city's major water supplies it was found that this source, too, was deficient. The average value measured for the fresh drinking water was only 0.025 $\mu\text{c. per litre}$; this corresponds to only about 0.02 $\mu\text{c. per gm.}$ of sewage (having 1,250 p.p.m. total solids), so that fresh water could contribute only about 6 per cent of the caesium-137 observed in the sewage.

Anderson⁴ has considered in some detail the available reports concerning U.S. national dietary habits, and by introducing values of caesium-137 found in foods, he has ventured a rough estimate of the amount of caesium-137 that was daily ingested per person in 1956. There are several reasons for concluding that the value he derived, about 50 $\mu\text{c. per day}$ per person, would become no smaller if it could be corrected by deriving it from data pertaining to the spring of this year. If this value is tentatively accepted, and also if the estimates are taken that 2.8 million people contribute to a system carrying 250 million gallons per day and 1,250 p.p.m. total

solids, then a possible daily input of caesium is discovered that is much larger than could come through drinking water. In fact these, apparently conservative, values provide for roughly one-third of the average caesium observed in sewage early this year. To this, of course, must be added a contribution from garbage now frequently disposed of through kitchen grinders in this community.

No attempt will be made to balance the budget precisely, but use here of a 1956 fall-out contamination value needs some justification. After 1956 world-wide fall-out increased in rate; later it decreased⁵. During the period of these investigations at Hyperion the concentration of caesium-137 in dried milk from three nearby milk-sheds varied as shown at the top of Fig. 1. Milk is reported to be the largest contributor of caesium-137 in diet, and the concentrations in dried milk reported for the spring of 1960 are not strikingly different from those reported for 1956. Between these dates there were higher levels in almost every food; and almost every food in practice experiences a lag before it is delivered and consumed. There is also a substantial lag that occurs between input and output of caesium in the human system^{4,6}. It would therefore appear necessary to correlate sewage concentrations not with contemporary food contaminations but with concentrations measured in foods produced several months earlier. Because of these circumstances, it appears quite possible that the basic trend of caesium-137 in the Hyperion sewage could be controlled almost entirely by fall-out caesium entering through human food.

In many circumstances caesium behaves chemically and biologically like potassium, an essential tissue constituent; nevertheless there are several biological systems reported where a clear distinction is made between these two elements. In some cases, the discrimination has been observed to be against the intake of caesium and in favour of potassium; for example, plants are reported to discriminate strongly against radiocaesium in taking the two elements up from the soil.

Concentration and digestion of sewage depends largely on metabolic processes, and much of the final solid material has been synthesized by micro-organisms. Therefore, it was not anticipated that caesium would become strongly concentrated in the solid digested fraction relative to potassium. Table 2 indicates that caesium-137 is enriched relative to potassium by forty-fold during the reduction of sewage to digested, dried fertilizer. This aspect is being studied further.

Although it appears that the sewage system studied can collect the minute traces of fall-out caesium passing through in human food, the effect on the sea

cannot be great. This is because surface sea waters have caught and have failed to dissipate downward such large amounts of fall-out that the concentration of caesium-137 persists at levels not far below what is seen in average sewage. Measurements¹ made of the caesium-137 concentration in the local surface sea water early this year by us, gave an average of about 0.1 $\mu\text{C.}$ per litre. This should be compared with the value of 0.4 $\mu\text{C.}$ per litre representing the average concentration in the Hyperion sewage at the same period.

It is useful to compare average concentrations in this manner, but it should be pointed out that even in specimens taken from nearby points in the open sea the concentration may vary by more than 50 per cent. Smaller average concentrations were measured^{2,3} in local coastal waters than in waters far off this coast; and Yamagata⁷ has reported the average concentration for 1959 Japanese coastal water of 0.38 $\mu\text{C.}$ per litre, or essentially what has been observed in Hyperion sewage.

Even the peak concentrations observed at this plant should cause no alarm. From plant characteristics, it may be estimated that the largest peak in Fig. 1 corresponds to a batch input of about 0.4 curie. However, the sewage travels on the average 30 miles to the plant and is not likely to pass through in much less than one day, and the 250 million gallons of water put through in one day would dilute this to an average concentration of only 3.7×10^{-7} $\mu\text{C.}/\text{ml.}$ This falls far below the value of 2×10^{-5} $\mu\text{C.}/\text{ml.}$ now accepted as maximum permissible concentration for this particular isotope in water that is to be drunk continually by humans.

From these investigations something has been learned concerning the behaviour of radiocaesium in a

large modern sewage disposal plant, and useful conclusions can be drawn concerning the probable influence on the downstream environment. It can be seen, for example, that the original objective of following the local dispersal of sewage by the ocean can be attained only if the most sensitive and refined methods are applied. It appears, too, that suitable monitoring of the gamma-ray activities in sewage systems might provide additional safeguards to the public against misuse of the radioactive materials that are becoming more and more common in research, medicine and in industry.

This work was supported by the United States Atomic Energy Commission under Contract No. AT(11-1)-34, sponsored by Dr. A. B. Joseph, and made use of facilities supplied by the United States Office of Naval Research under Contract Nonr-233(34), sponsored by Dr. William Thaler. We are particularly indebted to Prof. J. E. McKee of the California Institute of Technology for consultations, and wish to acknowledge the co-operation of the professional staff of the Bureau of Sanitation of the City of Los Angeles, especially N. B. Hume, R. D. Bargman, J. M. Parkes, G. A. Betz, W. F. Garber, and C. G. Gunnerson. We are grateful to Dr. E. C. Anderson for supplying before publication the values for dried milk seen in Fig. 1.

OBITUARIES

Dr. J. M. Cowan, C.B.E.

WITH the sudden death of Dr. John Macqueen Cowan on the evening of October 26, after a very happy day with his friends on the Gardens Committee of the National Trust for Scotland, Scotland lost one of her most distinguished horticulturists.

A son of the manse, he was born in Banchory, Kincardineshire, in 1892, received his early education at Gordon's College, Aberdeen, attended the University of Edinburgh, taking the arts and science degrees with honours in botany, became an undergraduate at Oxford, reading honours in botany with Prof. Vines and Dr. Church and forestry with Sir William Schlich, before being appointed to the Indian Forest Service. At Oxford he met Adeline May Organe, who took an honours degree in botany, whom he married and who at all times was the source of the greatest possible encouragement to him; in fact, she was co-author of one of his earliest publications, "The Trees of Northern Bengal" (1929). In India he followed the example of some of his distinguished predecessors in the Forest Service, such as Brandis, Lace and Gamble, pursuing his botanical investigations as well as proving himself a forest officer of outstanding merit. It was not surprising, therefore, that from that Service he was chosen to officiate as superintendent

of the Royal Botanic Gardens, Calcutta, the chief botanical post in the Indian Empire.

Retiring from India in 1928 and after undertaking, with Dr. C. D. Darlington, a botanical expedition to Iraq and Persia, on behalf of Kew and the John Innes Horticultural Institution, Cowan returned to Scotland in 1930 as assistant to Sir William Wright Smith, the regius keeper of the Royal Botanic Garden, Edinburgh. Soon he was deeply engrossed in the taxonomy of the genus *Rhododendron*, the genus which had fired the enthusiasm not only of his immediate chief but also of the professor who had lectured to him as an Edinburgh student, Sir Isaac Bayley Balfour. On the taxonomy of this complex genus he published widely, often in collaboration with his Edinburgh colleagues; he published, too, on the genera *Cyananthus*, *Roscoea*, *Wendlandia* and others, as well as on the history of the Royal Botanic Garden. At all times he took a keen interest in the welfare of the horticultural students in the Garden, and if at times the students were not altogether approving of some of his teaching methods, they were always appreciative of the generous hospitality of the Cowan household.

Late in the 1940's Cowan became deeply interested in the activities of the National Trust for Scotland,

and especially interested in the two great Scottish gardens the Trust took over—Crathes in Kincardineshire and Inverewe in Ross and Cromarty. He gave great prestige to the Trust when, under the Trust's auspices, he inaugurated the early 'Garden Cruises', a unique and previously unused method of transport which has enabled people from all parts of the world to visit famous, and sometimes somewhat inaccessible, gardens in great comfort.

Happy and industrious though he had been in India, and undoubtedly was in Edinburgh, he frankly admitted that not until he retired from Edinburgh in 1954 and accepted the post of gardens adviser to the National Trust for Scotland, with his headquarters at Inverewe House on the incredibly lovely and rocky peninsula at Poolewe, did complete contentment and satisfaction come to him; and naturally so, when through his great energy and drive he saw the number of visitors to the Garden steadily increase from a few hundreds in 1954 to 47,000 in 1960.

Cowan's services to horticulture were acknowledged by the Royal Horticultural Society by the award of the Veitch Memorial Medal in 1951 and by the Victoria Medal of Honour in 1955. He was made C.B.E. in 1952. Mrs. Cowan and a son and daughter survive him.

H. R. FLETCHER

Prof. Yehuda Hirshberg

PROF. YEHUDA HIRSHBERG, head of the Laboratory of Photochemistry and Spectroscopy in the Weizmann Institute in Rehovoth, Israel, died on September 20. Prof. Hirshberg was born in 1903, went to Israel as a pioneer in 1923 and joined a Kibbutz. After a strenuous year he fell ill with malaria, and was compelled to move to Jerusalem. There he worked as a labourer and at the same time enrolled as one of the first students in the pre-faculty of sciences of the Hebrew University. He studied chemistry under Prof. A. Fodor, and graduated in 1928 (unofficially, since the Hebrew University was not yet recognized at the time). Being an outstanding student, he was given a study grant which enabled him to go to Brussels, where he continued his studies towards the degree of doctor of science under two distinguished teachers—Victor Henry and Jacques Errera. Despite the difficulties of a new language and environment, he completed his studies with great distinction, and was appointed an assistant. His first independent research paper was published in 1932. A year later he made the acquaintance of Chaim Weizmann, who soon recognized the high qualities of the young scientist and invited him to serve as the physical chemist of the Daniel Sieff Research Institute which was planned at the time. Thus began Hirshberg's life-long association with the Sieff and Weizmann Institutes. His scientific career can truly be called a fruitful one, as witnessed by nearly ninety research papers in various scientific journals. His well-known discovery of 'photochromism' in 1950 and the investigation of this phenomenon and of the 'photochemical memory' led by him since then, won him world-wide recognition and international acclaim.

Despite his success, he never ceased to be a 'man of the people', being on friendly terms with everybody, irrespective of grade or standing. His personality was marked by boundless devotion to his work, willingness to help, and eagerness to make a

friend of whomever he met, a goal which he achieved almost always, thanks to his rich Jewish humour and his good-heartedness.

His last years were marred by great suffering because of his many maladies. Nevertheless, he put up a stubborn fight against his disease and refused to give in. He was active in the laboratory and full of plans to his last day, and succumbed to a heart attack while still wearing his white laboratory coat.

His colleagues and collaborators will always remember his high human qualities, his scientific ingenuity, and his infectious enthusiasm, and hope that the work being continued in his laboratory will serve as a living monument to him.

E. FISCHER

Dr. Robert W. Lawson

ROBERT WILLIAM LAWSON, who died in hospital on November 14 in his seventy-first year, was a lecturer in the Physics Department of the University of Sheffield for thirty-six years. He went from his native town of Gateshead to Armstrong College (now King's College), Newcastle upon Tyne, in 1908 and obtained a first-class degree with honours in physics. This was followed by two years research work in the College on the production of those high-frequency oscillations which later developed into radio-waves, but the study of which was then in its infancy. This brought him an award which enabled him to go to the Radium Institute in Vienna in early 1914. He was interned on the outbreak of war but generously released on parole, so that he could continue his researches into radioactivity at the Institute. He worked long hours under difficult conditions, on an inadequate diet, and published a number of papers, particularly on the rate of emission of alpha-particles from radium. The result he obtained in this investigation was verified by later workers and is accepted as the standard value. These papers earned him the award of the degree of doctor of science of his own University of Durham. He also became one of the first Fellows of the Institute of Physics when it was founded.

On his return to Britain in 1919, Lawson was appointed a lecturer in physics at Sheffield and remained there for the rest of his life, being made a senior lecturer on the establishment of this grade. The privations he suffered in Vienna had an adverse effect on his health, and it was some time before this was sufficiently restored for him to resume experimental research. The work of teaching the influx of ex-Service students could not be deferred, however, and at once he entered on a life of service to the Physics Department. He was a lucid lecturer and it was his delight to give experimental demonstrations of his talks whenever possible. In the early nineteen-twenties he was placed in charge of the laboratories in which both the special and general degree students worked. Thus he had a large share in training the many Sheffield physicists who have attained distinction. He devised many ingenious experiments for them, some of which were shown at the open meetings of the Sheffield Physical Society which he organized between the two World Wars. He had a wide circle of friends among Continental physicists, and this, together with his proficiency in German, led to the publication of several translations of important books. Probably the most noteworthy of these was "Relativity", by Einstein, the first simple exposition of the theory which has affected science

so profoundly. His colleagues benefited from his wide reading, and in past years he was also a frequent contributor to the columns of *Nature*.

Lawson played a prominent part in the formation of the Non-Professorial Staff Association of the University and was one of its first representatives

on the Senate when this recognition was accorded. He retired in 1955, but his interest in physics remained unabated. His unexpected death will be a shock to his old students, who had a high regard for him, and to his many friends. He married in 1922 and leaves a widow and daughter.
J. R. CLARKE

NEWS and VIEWS

Inorganic and Structural Chemistry at Leeds:

Prof. H. M. N. H. Irving

DR. H. M. N. H. IRVING has been appointed to the chair of inorganic and structural chemistry in the University of Leeds, in succession to Prof. E. G. Cox (see *Nature*, 185, 144; 1960). Dr. Irving was born in Oxford in 1905 and educated at St. Bees School and Queen's College, Oxford, where he was a pupil of F. D. Chattaway. He took a 'first' in chemistry in 1928, a D.Phil. in 1930 and was awarded the degree of D.Sc. in 1958. He became a demonstrator in Queen's College laboratory, but when this closed down Prof. Soddy appointed him as a demonstrator in the Inorganic Chemistry Laboratory of the University. Although his early training was in the field of organic chemistry, he rapidly acquired a mastery of inorganic chemistry, and skilfully used his knowledge of organic synthesis, and familiarity with a wide range of organic substances, in an attack on various analytical problems and particularly in the application of stereochemical principles to their solution. Later he exploited solvent extraction and radiochemical methods to good effect. In these fields he has built up an international reputation. During the War he was engaged on government research problems and took an active part in local Civil Defence. He was a lecturer at St. Edmund Hall during 1935-38, and has been an official Fellow from 1938 and vice-principal since 1951. He has played an active part in the Chemical Society, Royal Institute of Chemistry and the Society for Analytical Chemistry, and has served on numerous official committees. He is the author of nearly a hundred papers on scientific subjects, and in addition to many interests outside his ordinary work he holds the licentiate of the Royal Academy of Music.

Psychological Medicine in Edinburgh:

Prof. G. M. Carstairs

DR. GEORGE MORRISON CARSTAIRS, director of the Medical Research Council Unit for Research on the Epidemiology of Psychiatric Illness, Tavistock Square, London, has been appointed to the chair of psychological medicine in the University of Edinburgh in succession to the late Prof. Alexander Kennedy. Dr. Carstairs was born in India and educated at George Watson's College and the University of Edinburgh. At the University he read arts as well as medicine and was a medallist in Fine Art. He was also a well-known athlete. He served as a medical officer in the Royal Air Force in Europe and the Far East. During the War, Dr. Carstairs became interested in social anthropology, particularly in studies of the influence of different cultural environments in personality development. After the War, Dr. Carstairs held various senior appointments at mental hospitals in Edinburgh and Oxford, and also studied social anthropology as an external student of

the Institute of Social Anthropology. For the next four years he held research fellowships which first took him to New York as a Commonwealth Fund Fellow, where he studied social anthropology under Dr. Margaret Mead during 1948 and 1949 in preparation for two years of field studies in Rajputana, where he carried out research while living in three primitive village communities. During part of this time he held a Rockefeller Grant and a fellowship from the Henderson Trust and worked as a graduate student of Cambridge under the direction of Prof. Meyer Fortes. His researches in Rajputana are published in his book, "The Twice Born". He has also published widely in psychiatry and in the psychiatric aspects of social anthropology.

Lister Medal of the Royal College of Surgeons:

Prof. W. G. Penfield, O.M., C.M.G., F.R.S.

PROF. WILDER GRAVES PENFIELD, director of the Montreal Neurological Institute, has been awarded the Lister Medal of the Royal College of Surgeons of England, in recognition of his service to the advancement of medical and biological knowledge, especially in the fields of neurology, surgical neurology, and psychology; and equally as humane surgical healer and as scientific research worker. He will deliver the Lister Memorial Lecture in London on April 5, 1961, under the auspices of the Royal College of Surgeons of England. This is the thirteenth occasion of the award, which is made by a committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh and the University of Glasgow.

Code of Practice against Radiation Hazards

A CODE of practice issued by the Imperial College of Science and Technology, University of London, describes the rules applicable to the use of equipment producing X-rays, to particle accelerators, and to the use of radioactive isotopes, either sealed or unsealed (Third edition, revised. Pp. v+35. London: Imperial College of Science and Technology, 1960). The code supersedes a previous one of December 1958, and deals, in the main, with administrative procedure and control; a second part consists of a number of appendices giving detailed information and advice on practice. The purpose of the code is set out under the following headings: (1) the protection of the worker's health; the hazard includes direct radiation and the accumulation of traces of radioactive material in the body; (2) the avoidance of contamination of the laboratory; (3) to ensure the safe disposal of waste material and effluent. The code also describes the method of control, the names of referees and the health physicist, the kind of work to be registered and the procedure for registration. Conditions to be observed before work is begun are also described.

Parliamentary Secretary to the Minister for Science

IN moving the second reading of the Ministers of the Crown (Parliamentary Secretaries) Bill in the House of Lords on December 8, the Minister for Science, Lord Hailsham, referred to the clause which permitted the appointment of a Parliamentary Secretary to the Minister for Science (see also *Nature*, December 3, p. 782). He said that the arrangement under which questions relating to responsibilities of the Minister for Science were answered by some six or seven different spokesmen in the House of Commons was neither popular in that House nor convenient to him. It frustrated what he thought was a main advantage in appointing a Minister for Science, namely, the production of an image of scientific policy as a consistent whole. A collection of spokesmen, however skilful, could not answer supplementary questions in the same way as someone in the Department who knew the mind of the Minister, and there was much background which could not be conveyed in the ordinary brief. He thought that the present practice prevented the building up and presentation as a whole of a coherent body of doctrine about the work of the Department. Lord Hailsham did not accept the view that the Minister for Science should necessarily be in the House of Commons. He thought there were advantages in the Minister being in the House of Lords, which might even be the ideal position; but he suggested that the Prime Minister is entitled to some latitude in this respect, and in this view Lord Alexander of Hillsborough, speaking for the Opposition, concurred.

Termites in the Humid Tropics

A SYMPOSIUM on "Termites in the Humid Tropics", organized jointly by Unesco and the Zoological Survey of India, was held in New Delhi during October 4-12 under the presidency of Dr. M. L. Roonwal, director of the Zoological Survey. Among the eighty-four registered participants were delegates from Burma, Ceylon, Indonesia, Pakistan and Thailand. In addition, Prof. A. E. Emerson (University of Chicago), Prof. M. S. Ghilarov (Academy of Sciences, Moscow), Prof. K. Gösswald (University of Würzburg) and W. V. Harris (Commonwealth Institute of Entomology, London) attended as guests of Unesco.

Some forty papers were submitted, the majority of which were read and discussed at one or other of the six sections—systematics and morphology, physiology and development, general biology, ecology, intestinal symbionts and termite control. Current research in India provided the basis for many of the communications. An interesting series of papers was contributed by workers at the Defence Research Laboratories, Kanpur, covering the laboratory culture of *Odontotermes* for testing purposes, the ecology of fungus gardens constructed by this genus, and the relative susceptibility of local timbers to termites. The development of the *Odontotermes redemanni* embryo was dealt with by D. Mukerji in a beautifully illustrated paper. Other communications dealt with regressive evolution among termites (A. E. Emerson), the termite fauna of the U.S.S.R. (M. S. Ghilarov), termites in relation to Indian agriculture (D. B. Reddy and T. Sankaran), a portable plant for termite-proofing timber, bamboo and thatch used for low-cost buildings (V. R. Sonti), to mention only a few. It is understood that the

proceedings of the symposium will be published in due course by Unesco.

At the final plenary session a resolution was passed recommending to the consideration of Unesco the appointment of an International Termite Commission to undertake, among other things, the co-ordination of testing techniques for termite-proof materials, the study of the problem of accidental introduction of injurious termites, and the collection of information on termites as pests of growing crops and methods of control. A field excursion to the Forest Research Institute, Dehra Dun, provided a welcome break in a well-organized, but rather concentrated, programme of meetings, public lectures and broadcasts.

Trinidad and Tobago Coconut Research, Ltd.

THE new Research Station situated at Champs Fleurs, Trinidad, West Indies, is an institution intended to foster research relative to coconuts. It is administered by the Directors of Trinidad and Tobago Coconut Research, Ltd., which is a non-profit making company financed jointly by West Indian Oil Industries, Ltd., Trinidad Manufacturing and Refining Co., Ltd., and the Coconut Growers' Association. The Station will be concerned with all problems pertinent to the cultivation of coconuts, with the ultimate object of increasing copra production at a decreased cost. The Station stands in the West Indian Oil Industries Compound and comprises a well-equipped laboratory, offices and stores. Relevant scientific periodicals and text-books will be collected to form the nucleus of a library to be located in the main building. The depredation of the destructive red ring disease of coconuts will compel the research team to devote most of its energies to this problem, but, as time permits, attention will be paid to other problems. It is hoped to study the insect pests of coconuts with special reference to their role as vectors of red ring disease: in this context particular attention will be paid to the coconut palm weevil (*Rhynchophorus palmarum*), and means of controlling this pest will be sought. The nutrition of palms will be investigated, again in relation to red ring, but it is hoped that the results of this work will also help in the framing of general recommendations for manuring programmes. Up-to-date summaries of literature on any coconut problems which appear to be causing concern in different parts of the territory will be circulated and it is thus hoped to keep the planting community informed of the results of research into this valuable crop.

Resistant Strains of Micro-organisms

It is to be expected, and accepted, that micro-organisms inhabiting the gut of animals in the presence of antibacterial substances, such as antibiotics, will be either naturally or developmentally resistant to those substances. It is neither to be expected nor accepted that this state of affairs is necessarily undesirable or such resistant strains necessarily of enhanced pathogenicity or virulence; indeed, the evidence of animal well-being on antibiotic-supplemented diets is overwhelmingly to the contrary. However, caution is justifiable, despite the continuing lack of adverse practical or experimental data in the veterinary field, being engendered to a considerable extent by experience in human medicine with resistant *Staphylococci*; here, though, both environment and dosage-levels are very different. A recent communication in *Nature* (187, 288; 1960) described the isolation by Williams Smith and Crabb

of resistant *Staphylococci* from pigs and chickens and from their attendants; most of these organisms were resistant to 'nutritional levels' of the antibiotics fed to the animals and would be expected still to be sensitive to therapeutic dosage-levels. More recently Williams Smith (*Res. Vet. Sci.*, 1, 182; 1960) has shown that the widespread use of antibiotics in pig feeding in Britain has had no pronounced effect in increasing the number of resistant *Salmonellae* in the general pig population. This is highly significant (or insignificant?) epidemiologically, and is of particular interest in contrast with the observations of Garside, Gordon and Tucker (*Res. Vet. Sci.*, 1, 184; 1960) on experimental *Salmonella typhimurium* infection in chickens, concerning the possible effects of 'nutritionally induced' antibiotic resistance on the *Salmonella* carrier state. However, high levels of antibiotic feed supplementation were used for prolonged periods in some of their experiments, exaggerating the degree and persistence of the bacterial antibiotic resistance thus induced. Moreover, there was no evidence of any relationship between resistance, pathogenicity and virulence; it is thus important that, should problems exist, they would not relate to unduly malignant organisms of enhanced potency.

The High Polymer Research Group

THE High Polymer Research Group has been founded under the chairmanship of Sir Harry Melville, for the purpose of organizing study conferences. The first conference, which will be held during April 17-20, 1961, will consider the relationship between chemical structure and physical properties of elastomers. The policy of the Group is to encourage the free exchange of ideas between active workers from all countries in the chosen field, and for that reason participation will be by invitation only. The proceedings of the Group will not be recorded, nor will papers which are read before the Group be available for publication. The offices of the Group are at 14 Belgrave Square, London, S.W.1.

Historic Books on Mining and Kindred Subjects

RECENTLY the Science Museum, South Kensington, has staged No. 4 of its occasional exhibits of historic books on scientific and technological subjects. This new exhibition is of works on metalliferous mining, metallurgy, mining machinery, mining laws and customs, mineralogy, precious stones and related subjects (see *Nature*, 188, 538; 1960). The books themselves have been generously lent to the Museum by Mr. Robert Annan, a mining engineer, from his private collection. Many are illustrated, and nearly all are of considerable rarity. Mining is perhaps the oldest of human industries, extending back into prehistoric times, when flints were mined to make implements. Records of early mining activities before the commencement of printing are naturally very scarce, but the exhibit contains a reproduction of the illustrated title page of a fifteenth century manuscript, the "Kuttenberger Kanzionale". This is primarily a treasury of old mining songs, but contains illustrations that form a valuable record of the life and activities of a mining community of the period. The printed books cover the period from the late fifteenth to the early nineteenth century. Opportunities for the public to examine such a comprehensive collection of classic mining works occur very seldom indeed, and this exhibit should not be missed by those interested. The exhibition will remain open

until December 31. An annotated catalogue has been issued, which can be obtained from the Museum, or from H.M. Stationery Office (Book Exhibitions, No. 4: Historic Books on Mining and Kindred Subjects. Pp. 32. 1s. 6d.).

Theoretical Atomic Physics In Norway

DURING the period covered by its second annual report (1958-59), the Nordisk Organization for Teoretisk Atomfysik was still operating on an interim basis, since the adoption of the convention on which its activities are to be based formally has had to be postponed (Pp. 46. Copenhagen: Nordisk Organization for Teoretisk Atomfysik, 1960). The temporary board, consisting of four members each from Denmark and Norway, three from Finland and Sweden, and one from Iceland, with Prof. Niels Bohr as chairman, held two meetings during the year. The staff on June 30, 1959, consisted of Prof. C. Møller as director and three scientific and three administrative staff. There were eleven Research Fellows. As in the previous year, courses of lectures and colloquia were held regularly, and detailed lists of these together with the papers published by members of Nordita are given in the report. Offprints of the papers appear as numbers in a series entitled "Nordita Publications", and are sent on request without charge to institutions and scientists interested in them. Notes of some of the lecture courses have also been issued and are similarly available.

Ergonomics and Automation

THE Department of Scientific and Industrial Research has sponsored a study of the human implications of automation. This was carried out under the direction of A. T. Welford and included a critical appraisal by Miss H. M. Clay and Mr. Welford of recent research, as well as a survey of existing practice in industry by E. R. F. W. Crossman. Two publications have now been issued in the series "Problems of Progress in Industry", describing these investigations. The first, "Ergonomics of Automation", describes research relevant to the problems of the human operator in an automatic plant, with special emphasis on the design of equipment (Problems of Progress in Industry, No. 8. Pp. 60. London: H.M. Stationery Office, 1960. 3s. 6d.). The second, "Automation and Skill", gives an account of the industrial survey, and discusses the skills required of human operators in highly mechanized and automatic plants, as well as problems of selection and training (No. 9. By E. R. F. W. Crossman. Pp. 59. London: H.M. Stationery Office, 1960. 3s. 6d.).

The National Museum, Bloemfontein

THE annual report of this Museum for the year ended March 31, 1960, forms encouraging reading as it records the near-completion of two new wings (Pp. 22. Bloemfontein: National Museum, 1960). This increased accommodation will give four exhibition halls and twelve extra workrooms for the staff. The latter provision will give much better facilities for research. A cafeteria has also been included. The building programme interfered with the normal activities of the Museum, and research and field work almost ceased. It has also entailed the withdrawal of the usual facilities to senior university students in anthropology and history. In spite of these additions to the buildings, exhibits illustrating the proto-bushman and fossil reptile-tracks have been prepared.

Thomas Anderson (1743/4–1812)

THE proceedings of the Scottish Society of the History of Medicine for 1959–60 is particularly interesting for the report of an address by Dr. Noel L. Poynter on the life of Thomas Anderson, the pioneer of vaccination in Scotland (Pp. 30+2 plates. Edinburgh: Scottish Society of the History of Medicine, 1960). In 1799, soon after an outbreak of cowpox in London, Anderson, "who had doubtless read the account of Jenner's *Inquiry* in Duncan's *Annals of Medicine* (12), wrote to Jenner in April asking for material to introduce vaccination in his own practice; he was able to accede immediately to his request". The excerpt from Duncan's *Annals* in the autumn of 1799 is attributed to Andrew Duncan, senior, and reads as follows: "In the village of Newhaven, in the neighbourhood of Edinburgh, many children have lately been inoculated with vaccinous matter, and they have from thence obtained complete protection against the natural disease, which then prevailed, and which still does prevail with great severity. And, indeed, from upwards of an hundred trials in Edinburgh and its environs, it has now appeared that inoculation with vaccinous matter affords equal protection against future small-pox, as inoculation with variolous matter. For these trials we are chiefly indebted to that very ingenious and able practitioner, Dr. Anderson of Leith, who was, we believe, the first to introduce vaccinous inoculation at this place, with matter which was sent him from London".

The Matjes River Rock Shelter

SOME time ago the Matjes River rock shelter was in part studied by the late Dr. Dreyer; now the excavation has been concluded by Dr. Louw as research leading to a Ph.D. degree (Researches of the National Museum, Bloemfontein. Memoir No. 1. The Museum, Bloemfontein, 1960). The result is a very competent work, and the finds have been examined in great detail. The rock shelter is in the extreme south of the African continent, roughly in the region of Plettenberg Bay. The finds include stone and bone implements, as well as skeletons. Five layers can be determined, labelled *A* to *E*. It would seem that everything found belongs to the Recent period and no trace of any true Middle Stone Age habitations occurs. The most interesting finds come from layer *C*: they recall those unearthed from the well-known Oakhurst shelter by the late Prof. Goodwin. At this time Wilton influences were penetrating into the region and mixing with the then existing folk, who would seem apparently to have been more of a *Smithfield* type. There are plenty of illustrations, but unfortunately they are not too good, especially those figuring the stone tools. Drawing stone implements is a specialized art, and the draughtsman must know a lot about stone knapping if a really useful illustration is to be produced. But it is excellent to gather that the study of this rock-shelter is now completed and Dreyer's beginnings brought to a conclusion. Most of the skeletons seem to be of a bushman or proto-bushman type.

Chromium in Water Supplies

THE need for research on the toxicity of chromium is emphasized in *Water Research News*, No. 9, July 1960—a periodical publication of the Water Research Association, Redhill, Surrey. In an article

on "The Problem of Chromium in Water Supplies" it is pointed out that there are possibilities of chromium reaching water supplies from industrial effluents. It is generally considered that this element, particularly in its hexavalent form, is toxic, and that only very small amounts should be permitted in water supplies—less than 0.05 p.p.m. hexavalent chromium is laid down in the Drinking Water Standards of the United States Public Health Service. Methods available for removing chromium from water are costly, and the Research Association suggests that more information on the effects of chromium on living creatures is required. The available data on the concentrations toxic to various organisms are conflicting, and there appears to be no information on the mechanism of its toxic action; research on this subject would appear to be an important step in determining permissible concentrations in water supplies. Another item in this issue gives a warning that polythene joints may fail if they are brought into contact with certain active compounds, which include various oils and detergents, and are then subjected to stress. It is recommended that jointing materials should be kept away from compression fittings used for polythene, and that if possible stresses in polythene fittings should be relieved by immersion in hot water.

BIO-RAD Laboratories: Supply of Deuterium Oxide

BIO-RAD Laboratories, 32nd and Griffin Avenue, Richmond, California, have announced that deuterium oxide, a component of nuclear reactors and a key material in basic studies involving biological systems and moderation of nuclear-particle paths, will be leased for periods ranging from three months to two years at a fraction of the cost of purchasing or producing the material. The heavy water (99.8 per cent) will be on a lease/purchase basis, and can be used as the customer desires. The water is returned to BIO-RAD Laboratories when and if the customer wishes, and he will receive a credit based on the length of time water has been kept and the amount of dilution it has undergone. Plans are now being considered for similar forms of lease covering other stable isotopes including nitrogen-15 and carbon-13.

American Academy of Arts and Sciences: Grants-in-Aid

GRANTS-IN-AID, usually ranging between 500 dollars and 1,500 dollars, are available from funds administered by the American Academy of Arts and Sciences for research in any recognized scientific field, including mathematics, physical, biological and the social sciences. Applications must be received before February 1 for grants to be made in March, and before September 1 for grants to be made in October. In general, applications from individual scientists rather than from institutions are favoured, although this is not an inflexible policy. Projects dealing with explorations of the frontiers of scientific knowledge, whether interdisciplinary or within a single discipline, are preferred. Support is not usually given for work aimed primarily at fulfilling the requirements of an academic degree, or for the purchase of non-expendable laboratory equipment. Further information and requests for application forms should be addressed to: Committees on Research Funds, American Academy of Arts and Sciences, 280 Newton Street, Brookline Station, Boston 46, Massachusetts.

David Anderson-Berry Prize (1961)

A DAVID ANDERSON-BERRY Medal, together with a sum of money amounting to not less than £100, will be awarded in 1961 by the Council of the Royal Society of Edinburgh. The Prize will be awarded for recent work on the effects of X-rays and other forms of radiation on living tissues. Published work will be taken into consideration if submitted to the Society with the application. In addition to direct application for the Prize, proposals may be made on behalf of others. Applications and proposals should be sent to the General Secretary, Royal Society of Edinburgh, 22/24 George Street, Edinburgh 2, not later than March 31, 1961.

University News :**Edinburgh**

THE title of Research Fellow in the Department of Animal Genetics has been conferred on Dr. J. L. Sirlin; Mr. D. M. Weir has been appointed lecturer in the Department of Bacteriology, and Dr. R. G. S. Leask has been appointed lecturer in the Department of Clinical Chemistry.

Glasgow

DR. J. H. RENWICK has been appointed senior lecturer in human genetics. The following have been appointed lecturers: R. W. P. Drever, W. Jack and E. W. Laing (experimental and theoretical physics); I. M. Hoodless and W. Parker (chemistry); J. S. Keates (geography); and D. J. Simms (mathematics). G. L. le Bouvier has been appointed to a research fellowship in genetics, and I. Hughes and D. A. R. Wallace in mathematics. A. L. Porte has been appointed an Imperial Chemical Industries Fellow in chemistry.

The second Fleck Lecture is to be given on February 22, 1961, by Dr. John Paul (biochemistry).

For the present session, 396 new students (286 men and 110 women) have been admitted to the Science Departments, compared with 392 in 1959. The total of matriculated students in the University as a whole now stands at 6,600, compared with 6,566 in 1959.

London

DR. D. G. EVANS, director of the Department of Biological Standards in the National Institute for Medical Research, has been appointed to the University chair of bacteriology and immunology tenable at the London School of Hygiene and Tropical Medicine. Dr. J. D. N. Hill, senior lecturer in the Institute of Psychiatry and lecturer in psychological medicine at King's College Hospital Medical School, has been appointed to the University chair of psychiatry tenable at Middlesex Hospital Medical School.

Announcements

DR. S. M. PARTRIDGE has been appointed head of the Eggs and Poultry Department of the Low Temperature Research Station, Cambridge, following the death of Dr. J. Brooks (see *Nature*, 188, 451; 1960). Dr. Partridge will also continue to be in charge of the Protein and Ion-Exchange Department.

DR. H. E. DADSWELL has been appointed chief of the Division of Forest Products of the Commonwealth Scientific and Industrial Research Organization, Australia. He succeeds Mr. S. A. Clarke, who retired in August. Dr. Dadswell, who has been with the Division since its inception, was previously assistant chief and officer-in-charge of the Division's Wood and Fibre Structure Section.

DR. J. R. FURLONG, scientific adviser since 1953 to the Pyrethrum Board of Kenya, has retired and will take charge of the London office of the African Pyrethrum Technical Information Centre in succession to Dr. T. F. West, who has been appointed editor of *Chemistry and Industry*, the journal of the Society of Chemical Industry. Dr. Furlong was chairman of the Consultative Committee on Insecticides of Vegetable Origin at the Imperial Institute, and in 1946 he took a leading part in the survey of methods for the analysis of pyrethrum, which resulted in the world-wide collaborative scheme carried out in 1948-49.

D. VAN NOSTRAND CO., LTD, regret to state that there are mistakes in titles of authors mentioned in their advertisement of the "International Dictionary of Applied Mathematics", published in *Nature* of December 10 (p. i of Supplement); thus Prof. B. H. Flowers, author of the section on "Nuclear Science", is now professor of theoretical physics in the University of Manchester; the section on "Aerodynamics and Hydrodynamics" is by Prof. W. A. Mair and Dr. R. S. Scorer, and that on "Probability and Statistics" by Prof. M. G. Kendall.

THE Faraday Society is holding an informal discussion on "Mechanisms of the Gas-phase Reactions of the Halogens and their Compounds" in the Chemistry Department, University College, Cardiff, on March 28, 1961. Further information can be obtained from Dr. J. H. Thomas, Chemistry Department, University College, Cathays Park, Cardiff.

A SYMPOSIUM on "Molecular Structure and Spectroscopy" is to be held in the Department of Physics and Astronomy, Ohio State University, during June 12-16, 1961. Further information can be obtained from Prof. R. A. Oetjen, Department of Physics and Astronomy, Ohio State University, Columbus 10, Ohio.

THE first international congress on "Metallic Corrosion" is to be held at the Imperial College of Science and Technology, South Kensington, London, S.W.7, during April 10-15, 1961. Further information can be obtained from the Honorary Secretary, First International Congress on Metallic Corrosion, 14 Belgrave Square, London, S.W.1.

THE Mather Lecture for 1961 will be given in conjunction with the annual general meeting of the Textile Institute to be held on April 20. The Lecture will be given by Dr. A. Clow, senior producer of the Science Unit of the British Broadcasting Corporation, and his subject will be "Chemistry in Scotland and its Pioneer Contributions to Textile Technology". Further information can be obtained from the Secretary, Textile Institute, 10 Blackfriars Street, Manchester 3.

ASKED for a statement on the Low Temperature Research Station, Cambridge, Mr. C. Soames, the Minister of Agriculture, Fisheries and Food, as representing the Minister for Science, in a written answer on November 24 stated that the building occupied by the Station was held on a 10-year lease from the University. The lease expired in 1966 and the University had given notice that it could not renew the lease as the space is required for other purposes. The Agricultural Research Council was considering the future of the work being carried on at the Station.

THE IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

NEW PHYSICS DEPARTMENT

IN 1953 the Government decided that, within a period of less than ten years, the size of the Imperial College of Science and Technology should be doubled. Plans were eventually prepared by the College for a massive expansion programme, involving the re-development of a large site in South Kensington, which culminated in the Jubilee scheme, announced by the College in 1957.

A significant stage in this expansion was reached on October 20, with the formal opening of the new physics building by Sir John Cockcroft. The Departments of Aeronautics and Chemical Engineering and part of the Department of Mechanical Engineering have already moved into new buildings during the past few years, but the Department of Physics is the first to be completely rehoused as part of the Jubilee scheme.

The new building has twelve floors (levels 0-11) in which the complete activities of the Department, both teaching and research, are carried out. Levels 0 and 1 are below ground-level, and levels 2-7, T-shaped in plan, rise 80 ft. above ground. Four more floors of smaller area (levels 8-11) extend the spine of the T some 50 ft. higher. The given area of 183,000 sq. ft. doubles the space provided by the old physics building, and it is interesting to note that this is provided on a site only half the size.

Teaching facilities are provided for 350-400 undergraduate students, and are confined to levels 1-4,

where large corridors and several staircases make for the easy movement of large numbers of students between lecture theatres and practical laboratories. There are three lecture theatres, the largest seating 250 and the others 150 each. The former is well equipped with ciné and still projectors, and with sound equipment. In addition to its use for undergraduate courses, it has been designed in conjunction with the entrance halls and the library reading room, with a view to the holding of scientific conferences.

The main practical instruction is given in three large teaching laboratories, each of which is provided with ancillary photographic dark rooms, preparation rooms and storage space. Library facilities have been considerably extended; the book capacity is 12,000 volumes, and tables and seating for 100 persons are available day and night.

The teaching of undergraduates, concentrated on the lower floors of the building, has been further co-ordinated by the appointment of Prof. W. D. Wright, who continues also to hold the chair of technical optics, to the new post of director of undergraduate studies. He, assisted by several other members of the academic staff, will arrange the undergraduate courses and generally supervise the facilities for students in the teaching areas of the building.

Below ground-level are some very large rooms, used as research laboratories for acoustics, high-temperature physics and spectroscopy. Here, too,

Fig. 1. New Physics Department of the Imperial College of Science and Technology, London

are the students' and main workshops, used largely for the construction of research apparatus.

The main research activity, however, takes place on the upper floors of the building—levels 5–11. Although laboratories individually designed for various types of work offer advantages in the first few years to the first occupants of a new building, these are usually far outweighed by the difficulties of adapting them later for use for new people and different research. Consequently, every effort has been made to avoid the specialized design of particular rooms. Throughout the research areas an attempt has been made to provide in rooms of all sizes a uniform high standard of background amenities.

Large, double-glazed windows provide good natural lighting, give acoustic and thermal insulation and can be blacked out completely or fitted with venetian blinds to avoid excessive glare or heating from the Sun. The building is completely ventilated with filtered air to minimize harm caused by dust on delicate apparatus and to reduce the inconvenience and cost of cleaning. Ceilings are faced with demountable acoustic tiles for quietness. These are also the source of heating, conceal some piped services and support recessed lights, so that clear plane interior surfaces are provided without restriction on the placing of apparatus. To further this flexibility in the use of rooms, recessed wall racks and concealed attachment points in the ceiling are provided for the erection of apparatus.

Electrical supplies are contained in surface-mounted aluminium wall ducts, water and gas on narrow wooden service rails. These are provided in nearly all rooms, so that even the smaller ones, which may be used as academic staff rooms or administrative offices, can equally well be used for experimental work. Practically no laboratory furniture is built-in, but is composed of standardized units which can be grouped together and, if necessary, bolted to the wall racks, according to particular needs.

The large ducts above the corridor ceilings and vertical ducts in the thickness of the corridor walls interconnect all rooms in the building. Initially these carry only those minimal supplies of electricity, water and gas for the work at present envisaged, but as new projects arise and require new supplies,

Fig. 2. Main entrance

readily accessible space in the ducts is available for them.

During the past five years a considerable expansion of the Department has already taken place, under great difficulties, in the old building, in preparation for the move into the new one. Physics undergraduates have increased by some 50 per cent to 315, and postgraduates by a similar proportion to about 90. Approximately 100 undergraduates from other departments also attend courses. A particular feature of the Department's development is the number of independent research groups which have been formed, each headed by its own professor. In addition to the long-standing Technical Optics Section, three more have been established in recent years: Instrument Technology, Theoretical Physics and Cloud Physics. At the same time three other professors have been appointed to assist the head of the Department, Prof. P. M. S. Blackett, in the direction of its other research activities, which now include high-energy nuclear physics, cosmic rays, electron diffraction, high-temperature physics, spectroscopy, acoustics, rock magnetism, electron physics and metal physics.

That such an active and flourishing expansion in the Department's activities should be matched with the environment and facilities of what must be one of the finest physics buildings in the world, gives promise of a great future for physics at the Imperial College.

N. C. BARFORD

THE NATIONAL CHEMICAL LABORATORY

THE National Chemical Laboratory held open days for visitors from industry, the universities and Government departments during October 19–21. The Laboratory's work was last on view in October 1958, shortly after the re-organization of the former Chemical Research Laboratory, so that this year's exhibition gave the first opportunity to inspect the changes and the progress made in implementing the revised research programme. Especially noteworthy, perhaps, were the increasing scope and facilities for

hydrometallurgical research, and the decision to develop the earlier work on the purification and physical properties of organic compounds into a full programme of chemical thermodynamics. Although the open days showed also the progress in the Laboratory's continuing lines of research, emphasis was on newer developments.

The Extraction of Metals Group, concerned with hydrometallurgical processes and their underlying chemistry, showed its new laboratory wing, occupied

Natural and Synthetic Bradykinin

SINCE the isolation of natural bradykinin by Elliott, Lewis and Horton¹, a nonapeptide has been synthesized^{2,3} and its structure agrees with that proposed⁴ for the natural product. The structure is as follows: Arg.Pro.Pro.Gly.Phe.Ser.Pro.Phe.Arg.

The reported pharmacological properties of the synthetic bradykinin^{5,6} appeared to be similar to those found with the natural product⁷. However, in order to establish the fact that the synthetic and the natural substances are the same, it was necessary to make a direct quantitative comparison of their pharmacological actions.

Table I. RATIO OF ACTIVITY OF NATURAL TO SYNTHETIC BRADYKININ

Biological activity and preparation	Natural/synthetic
Smooth muscle contracting activity	
Guinea pig ileum	1·0, 0·8, 1·0, 1·1
Rabbit duodenum	0·6, 0·8, 1·0
Rat uterus	1·4, 0·6, 1·0, 1·0
Smooth muscle relaxing activity	
Rat duodenum	0·8, 1·4, 1·1, 0·9
Rat colon	1·4, 0·7, 0·8, 0·8
Vasodilator activity	
Human forearm*	0·7, 1·0
Cat hind limb	1·0, 1·0, 0·9, 1·0
Depressor activity	
Cat blood pressure	1·0, 0·8, 0·9
Increased capillary permeability	
Guinea pig skin	1·0, 1·0, 0·9, 1·0, 1·0, 0·9
Rabbit skin	1·1, 1·0, 0·9, 1·0, 0·9, 0·8
Pain production	
Human blister base†	1·0, 1·0, 1·0, 1·0

Each numeral represents the result of one experiment. The numerals in bold type are the result of comparison with synthetic bradykinin made by Parke, Davis (which was 80 per cent pure), the remainder with that made by Sandoz (which contained 35 μ gm./ml.).

* From Fox, Goldsmith, Kidd and Lewis (ref. 8).

† This test was sufficiently accurate only to establish that the threshold dose of each sample was of the same order, that is, 10^{-7} gm./l.

The pure natural bradykinin of Elliott *et al.* was compared with two samples of synthetic bradykinin—one made by Sandoz, Ltd., and the other by Parke, Davis and Co.—on eleven different biological preparations. In Table I, the ratio of natural bradykinin to synthetic bradykinin is given for the activity on these eleven preparations, and in Fig. 1 the method of obtaining these ratios is illustrated for the vasodilator activity by comparing the responses to a range of doses varying between 0·5 μ gm. and 0·02 μ gm.

Within the limits of experimental error the sensitivity of all eleven preparations to both natural and

synthetic bradykinin was the same, proving that the natural and the synthetic bradykinin are identical.

Direct Comparisons of the Synthetic Nonapeptide with Trypsin Bradykinin

IN April 1960, Elliott, Lewis and Horton¹ proposed an octapeptide structure for bradykinin. This was synthesized and found inactive by three independent groups of workers²⁻⁴. After discussion between Boissonnas and Elliott⁵, Boissonnas, Guttman, Jaquenoud, Konzett and Stürmer⁶ described the nonapeptide L-arginyl-L-prolyl-L-prolyl-glycyl-L-phenylalanyl-L-seryl-L-prolyl-L-phenylalanyl-L-arginine, with properties resembling those of bradykinin. Elliott, Lewis and Horton⁷ have concluded on chemical grounds that trypsin bradykinin has the structure of this nonapeptide, and Konzett and Boissonnas⁸ have recently published biological evidence supporting the view that this peptide is identical with bradykinin.

The present work aimed at comparing directly on several biological preparations the synthetic nonapeptide with bradykinin to provide further evidence bearing on the question whether the two substances are identical. We used a specimen of the nonapeptide synthesized by Nicolaides and De Wald⁷ and specimens of highly purified trypsin bradykinin (85 and 30 per cent pure) prepared by Elliott, Lewis and Horton⁸. In comparisons on the guinea pig ileum we also used a crude isolate of bradykinin (0·05 per cent pure) prepared by Lockhart and Jones⁹ by

Fig. 1. Cat, 2·5 kgm. anaesthetized with chloralose 60 mgm./kgm. Upper tracing record of venous outflow from the hind limb. Lower tracing arterial blood pressure. Close arterial injections of natural bradykinin (NB) and synthetic bradykinin (SB), 0·5, 0·1, 0·02 and 0·01 μ gm., and of saline (sal) 0·1 ml. and 0·2 ml. Comparison of the dose-response curves in this experiment gave a ratio of 1·0

Fig. 1. Guinea pig lungs *in vivo*. Bronchoconstrictor responses to nonapeptide (N) and 85 per cent pure bradykinin (B) and their suppression by calcium acetylsalicylate (CaA). Substances administered intravenously. The guinea pig weighed 580 gm.

the action of crystalline trypsin on heated bovine serum globulin and previously standardized against pure bradykinin. The results (Table 1) show no significant difference between relative potencies of nonapeptide and trypsin bradykinin on the three preparations. This specimen of nonapeptide appeared to contain roughly 70–90 per cent active substance.

On the guinea pig lungs *in vivo*, both nonapeptide and bradykinin caused bronchoconstriction (Fig. 1), which was suppressed by calcium acetylsalicylate¹⁰ (2 mgm./kgm., intravenous). Larger doses of nonapeptide or of bradykinin overcame this suppression.

The foregoing evidence supports the view that L-arginyl-L-prolyl-L-prolyl-glycyl-L-phenylalanyl-L-seryl-L-prolyl-L-phenylalanyl-L-arginine is identical

Table 1. COMPARATIVE POTENCIES OF NONAPEPTIDE AND TRYPSIN BRADYKININ ON THREE BIOLOGICAL PREPARATIONS

Biological preparation	Reference specimen of bradykinin (percentage purity)	Potency of nonapeptide in terms of pure bradykinin	95 per cent fiducial limits
Guinea pig ileum	85	0.75	0.58–0.94
	30	0.67	0.54–0.78
	0.05	0.68	0.64–0.72
Rabbit blood pressure	85	0.86	0.79–0.94
	30	0.85	0.79–0.92
	0.05	0.90	0.82–1.02
Rat uterus	85	0.71	0.49–0.94
	30	0.56	0.39–0.78
	85	0.86	0.76–0.99

with bradykinin prepared by the action of trypsin on bovine serum.

We thank Dr. Warner for statistical analyses.

MEMBRANOUS CYTOPLASMIC GRANULES IN INFANTILE AMAUROTIC IDIOCY

By PROF. R. D. TERRY and PROF. S. R. KOREY

Albert Einstein College of Medicine, New York-61

INFANTILE amaurotic idiocy is characterized chemically by an accumulation of gangliosides in the nervous system. It has been suggested that the gangliosides occur naturally in polymeric form and in association with polypeptides or proteins¹. The appearance of the involved neurons and results of histochemical investigations of this disease suggest that the ganglioside increase takes place within neurons and in some of their processes². In two chemically confirmed cases of infantile amaurotic idiocy, examination of neural tissue by the electron microscope revealed structures unique to this lipidosis and of theoretical importance. We are presenting the morphology of case 1 as illustrative and the analytical findings of both cases as supporting the clinical and histological diagnosis of infantile amaurotic idiocy as well as for their bearing on the morphological findings.

In case 1 the neurons within the central nervous system were everywhere distended and rounded. The few remaining Nissl granules were grouped about the nucleus, which was usually peripherally located. In paraffin-embedded material the neuronal cytoplasm

contained fine granules loosely packed in the largest cells and densely arranged in the smaller cells. This material in the most distended cells was very faintly positive in preparations stained with periodic acid-Schiff but more strongly positive in the dense neurons. The neuronal contents stained very pale yellow with sudan IV. They were strongly positive when stained by the iron haematoxylin method of Spielmeyer and Kultschitsky. Macrophages in the molecular layer, the white matter, and necrotic zones contained large amounts of fat stained brick red with sudan IV. Large reactive astrocytes were very prominent throughout. Severe neuronal loss was seen in the cerebellar granular layer. Myelin was best preserved in the corpus callosum, around the dentate nucleus and in the striate bundles of the basal ganglia. There was no particular sparing of subcortical association fibres.

The tissue fixed with formalin was treated with Palade's solution of veronal acetate buffered osmium tetroxide, embedded in methacrylate, sectioned on the Porter-Blum microtome and examined in a Siemens Elmiskop 1. The tissue was poorly preserved

Fig. 1. Close-packed cytoplasmic granules of both types ($\times c. 9,700$)

because it was a post-mortem specimen and had been previously fixed in acidic formalin. However, there were membranous granules measuring $0.5-2.0\mu$ in diameter very strikingly prominent in the neuronal cytoplasm (Fig. 1). These were of two general types. The more common was a sphere made up of spiral or concentrically layered membranes which were arranged in pairs of osmophilic lines separated by a clear zone (Fig. 2). The lines and the clear zone each measured about 25 Å. The membrane pairs were irregularly arranged and separated from each other. The second type of granule was ovoid and bounded by a paired membrane which enclosed close-packed, flat, paired lamellae. The membrane spacings were similar to those of the first type. Compound type granules with a concentric periphery and central flat lamellae were seen occasionally.

Membranous granules with similar characteristics were found in the second chemically confirmed case where the tissue was frozen immediately subsequent to autopsy. In a third case of infantile amaurotic idiocy cortical tissue fractions obtained by gradient centrifugation also contained these granules in a good state of preservation.

For determination of lipid constituents brain tissue of both cases was treated by the procedure of Folch³. This resulted in a chloroform lipid-rich phase, an aqueous phase containing gangliosides and water-soluble small molecules, and an insoluble residue, largely denatured protein, which was removed by filtration. The aqueous phase was dialysed extensively. In addition to the usual determinations for lipids in the chloroform phase, the phospholipids were identified chromatographically⁴. The gangliosides were estimated in the aqueous phase by sialic

acid-dependent methods^{5,6}. Amino sugars in the aqueous and lipid phases were determined following hydrolysis⁷ and separation on a 'Dowex' column⁸. The neutral sugars of the aqueous hydrolysate likewise were estimated following this separation and all the sugar fractions were chromatographed for identification. Cerebrosides were measured according to Svennerholm⁹ and Radin¹⁰.

Analysis of formalin-fixed and pathological material has several difficulties. With fraction and storage significant modifications of tissue constituents occur. In the presence of abnormal lipids or/and unusual proportions of normal lipid components, the distribution of these tissue components between the several phases may be affected.

In case 1 (Table 1) the amounts of insoluble residue and total lipid were not altered. The decrease in the phosphatide content may be the result of formalin fixation. The percentage of cholesterol esters in the white matter was slightly elevated and the cerebroside content depressed. Both changes can be related to demyelination. Hexosamine was increased in grey and white matter. The ganglioside content of grey matter was slightly increased and that of white matter markedly increased. During fixation in unbuffered solutions and storage the sialic acid moiety may be split from the remainder of the ganglioside molecule, and methods which depend on the measurement of sialic acid for estimation of gangliosides tend to lower results. This consideration is especially applicable to grey matter where changes consequent to fixation and storage occur most intensively. For this reason the hexosamine value in case 1 may be of greater significance (Edgar, G. W. F., personal communication). In this case as well as in case 2 the only sugars obtained following hydrolysis of the ganglioside fractions were galactosamine, galactose and glucose. The relative amounts of these sugars in the gangliosides obtained from pathological material may vary. This observation is now being investigated.

Case 2 (Table 1), which consisted of unfixed frozen tissue obtained several hours *post mortem*, demonstrated an elevation of lipid weight in grey matter. There was a great excess in the amount of lipid nitrogen found in the chloroform phase of the cortical tissue. The lipid nitrogen may be derived in part from gangliosides or their fragments which were distributed in the non-aqueous phase. This observation was supported by the increased amount of hexosamine found in the lipid phase. Also an adaptation of the Warren method⁶ applied to the chloroform lipid-rich phase indicated that there were components containing sialic acid in this layer. The ganglioside content of the aqueous phases of grey and white matter extracts, measured both by the Svennerholm⁹ and Warren⁶ methods, was markedly elevated. As mentioned in case 1, the amino and neutral sugars obtained following the hydrolysis of the ganglioside fraction were quantified, and identified chromatographically as galactosamine, galactose and glucose. The amounts of gangliosides calculated on the basis that they contain about 9 per cent hexosamine and 24 per cent neutral sugars⁷ were inconsistent with other data and again suggested either modifications of the gangliosides by the preparative procedures or the disease process, or the variability of methods of hydrolysis, isolation and measurement commonly employed. The remainder of the lipid analysis indicated that the total amounts of phospho-

Table 1. ANALYSIS OF BRAIN TISSUE OF CASE 1 (AGE 4 YEARS) AND CASE 2 (AGE 22 MONTHS)

The tissue of case 1 was fixed in formalin, while that of case 2 was frozen immediately *post mortem*. Normal values are to be found in the following references: 11, 12, 13, 14. Grey matter was a sample of frontal cortex, and white the adjacent subcortical region. Phospholipids of grey matter examined by paper chromatography (ref. 4) revealed sphingomyelin in case 2 to be about 11 per cent of the total phospholipids and of a similar amount in case 1. *a*, Calculated value; *b*, method of Svennerholm (ref. 5); *c*, method of Warren (ref. 6). phatides were within normal limits. There was an increase in lysophosphatides in grey matter noted chromatographically. There was a decrease in plasmalogen and cerebroside content of white matter, suggestive of myelin atrophy.

The main chemical findings support the diagnosis of infantile anaurotic idiocy. The identification of the membranous cytoplasmic granules with the accumulated gangliosides must await isolation of these membranous units and their chemical analysis. Such granules seem to be unique to this condition for they have not been noted in our examination (Terry, R. D., unpublished observations) of other types of lipidoses, nor are they structurally similar to lipofuscin granules. Based on their appearance it is likely that if the membranous units do contain major amounts of gangliosides these glycolipids are associated with proteins to form complex membrane structures.

Whether or not the membranes are derivatives of a normal organelle surface or a coincidental physical formation assumed by excessive or abnormal gangliosides requires consideration. It should be emphasized that there does not seem to be any morphological differences between the granules present in the formalin-fixed tissue and in representative samples from frozen unfixed tissue. This is of particular interest since the sialic acid content of gangliosides decreases with fixation in unbuffered formalin.

There are a number of observations which might indicate considerable order in the molecular constitution of the cytoplasmic granules. There is only limited variation in their structure with two main types being found; their size ranges from 0.5 to 2.0 microns; whenever good resolution was afforded, regular spacing of the membranous elements of their bodies was seen. Some of these issues may be clarified by the study of fractions of homogenized cortical tissue submitted to gradient centrifugation, by which means we have obtained concentrates of these granules.

This work was supported by National Institutes of Health Grants B-2255 (C1) and B-1006 (C4). We are indebted to Dr. Bruno W. Volk, director of the Isaac Albert Research Institute of the Jewish Chronic Disease Hospital, for making the material from case 2 available for study.

THE MOLECULAR DECOMPOSITION OF ALIPHATIC CARBONYL COMPOUNDS

By P. BORRELL*

Department of Physical Chemistry, Lensfield, Cambridge

It was first shown by Norrish *et al.*^{1,2} that the photolysis of the aldehydes and ketones proceeds by two mechanisms, which for methyl propyl ketone are:

The first of these is a scission of the bond adjacent to the carbonyl group forming free radicals, and is common to all ketones. The type II reaction is a direct rearrangement into molecular products and is confined to the higher members of the series. This

* Present address: The Frick Chemical Laboratory, Princeton, New Jersey.

reaction is not limited to the ketones alone but occurs in many other compounds containing a carbonyl group and takes place not only on photolysis but also on thermal decomposition, radiolysis, and electron impact. It is the purpose of this article to assemble the evidence and discuss the nature of the intramolecular split, and to show how the results allow the designation of certain electronically excited states to these molecules.

The Photochemical Breakdown

The type II reaction was first postulated by Norrish and Appleyard¹ in 1934 in a study of methyl butyl

ketone. Propylene was the major gaseous product and the reaction suggested was:

Later, Bamford and Norrish² noted the equivalent reaction with isovaleraldehyde and di-*n*-propyl ketone which form propylene and ethylene as their respective olefinic products. As an extension to this work, the photolysis was carried out, both in the vapour phase and in hydrocarbon solution to ascertain the nature of the primary reactions. The method, which utilizes the principle of Frank and Rabinowitsch³, relies on the free radicals formed in the primary act being confined together in a cage of solvent molecules. At low temperatures, recombination will predominate, lowering the quantum yield, while as the temperature is raised, the yields will be increased due to decomposition and hydrogenation of the free radicals. For a molecular split there is no difference on the change from vapour to solution. Although with di-*n*-propyl ketone, the type I reactions were shown to be exclusively free radical, the type II reaction, characterized by the quantum yield of ethylene, was entirely molecular, being invariant with environment and temperature.

More recently Blacet and Calvert⁵ have photolysed butyraldehyde in the presence of iodine and, while the type I products were modified by the radical trap, the yield of ethylene remained unchanged. It was also shown⁶ that although *n*-butyraldehyde decomposed intramolecularly, isobutyraldehyde formed no type II products. Thus three carbon atoms in a straight chain together with the carbonyl group are required for the reaction to occur.

Although Wilson and Noyes⁷ challenged the view that the type II reaction in the photolysis of methyl butyl ketone was intramolecular as the propylene to acetone ratio in their experiments was not unity, Nicholson⁸, repeating the work, found that the ratio remained unity over a wide range of conditions including photolysis in the presence of nitric oxide.

McNesby and Gordon⁹, after discovering a variation in product ratio with intensity in the photolysis of partially deuterated methyl propyl ketone, proposed a mechanism based on the interaction of two excited states. This is improbable in view of the solution work, where such a reaction is unlikely, and recently Ausloos and Murad¹⁰, after repeating the experiments, reported no variation.

These isotopic experiments indicate that the olefin is certainly formed from the β - and γ -carbon atoms in the molecule.

Experiments with cyclic ketones have thrown some further light on the mechanism: Bamford and Norrish¹¹ found that while cyclohexanone is photolysed by a type I mechanism alone, 1-menthone almost entirely decomposes by a type II reaction.

The isopropyl group is free to rotate and bring the γ -carbon atom close to the carbonyl group as in a free chain. This condition is not fulfilled with cyclohexanone.

The reaction is independent of temperature over a wide range: Masson showed that di-*n*-propyl ketone forms ethylene at a constant rate up to 160° C.¹², while Davies and Noyes showed that the quantum yield of acetone formation from methyl butyl ketone is constant up to 300° C.¹³.

The type II split is not limited to the aldehydes and ketones but is also present in the acids and esters. Borrell and Norrish¹⁴ have shown that ethylene is formed intramolecularly in the photolysis of both *n*-butyric acid and its methyl ester:

There is no evidence of the reaction with isobutyric acid which is thus similar to the isomeric butyraldehydes⁶. Although the carbonyl group is modified by the introduction of a hydroxyl group, the absorption is due to the same transition¹⁵ and the photochemistry should be similar. With a large group in the 'alcohol' position of the ester, another variation is possible: with ethyl acetate, for example, Ausloos¹⁶ found that ethylene forms a large proportion of the gaseous products:

Iodine has no effect on the yield in the vapour phase, and in solution ethylene is formed down to -70° C.

In addition to the group in the α position having little effect, it is also evident that the reaction is independent of the β group. Ketene is formed in the photolysis of acetic anhydride¹⁷ by the type II reaction:

Similarly, methyl ketene is produced from propionic anhydride. Even in very large molecules the reaction takes place, for Guillet and Norrish¹⁸ concluded that the characteristic split occurs in the photolysis of polymethyl vinyl ketone:

Wissburn has confirmed this result¹⁹.

The photochemical studies show that the reaction is intramolecular, independent of temperature, environment and radical traps. It requires at least three carbon atoms in a chain together with the carbonyl group, although the α group may be methylene or oxygen, and the β group may be methylene or another carbonyl group. The cyclic studies indicate that the γ -carbon atom must be free to rotate into the proximity of the carbonyl group.

Thermal Decomposition

In 1876, Oppenheim and Precht pyrolysed ethyl acetate and found the products to be acetic acid and ethylene; they postulated the reaction²⁰:

All the work carried out since then has confirmed the mechanism.

Hurd and Blunk²¹, reinvestigating the reaction, pyrolysed several esters in a static system and found that 85 per cent of the decomposition of ethyl and propyl acetates proceeded by an intramolecular split, while *t*-butyl acetate decomposed exclusively by this mechanism. Anderson and Rowley²² obtained similar results with various formates and showed the reaction to be first order. Blades²³ extended these studies using the toluene flow technique and could detect no evidence of a free-radical mechanism. The results are shown in Table 1.

Table 1

Compound	Activation energy (kcal./mole)	Activation entropy (e.u.)	Ref.
Ethyl formate	44.1	-10.7	23
Propyl formate	50	-18.7	22
Isopropyl formate	44	-4.9	23
Isopropyl formate	46.3	-5.35	22
Ethyl acetate	47.75	-5.4	23
Isopropyl acetate	47	-3.0	23
<i>t</i> -Butyl acetate	39.1	-4.0	24

The entropies of activation are calculated on the assumption that the transmission coefficient is unity, which is true if no change of electronic state is involved. The activation energies are much smaller than that required for a split into free radicals, and in the absence of any evidence of a chain process, the reaction must be molecular.

Barton²⁵, in studies of *cis* elimination in terpenes, has pyrolysed (-) menthyl benzoate (A), which forms benzoic acid and a mixture of *p*-menth-2-ene (B) 36 per cent and *p*-menth-3-ene (C) 64 per cent.

The decomposition is homogeneous and first order; it is considered further in the discussion.

The pyrolysis of acetates has been used for the preparation of olefins and it has been suggested that the reaction forms the least substituted olefin^{26,27}; for example, in the pyrolysis of methyl *isobutyl* carbonyl acetate, 4-methyl pent-1-ene is formed exclusively with no 2-olefin.

This conclusion, based on a number of studies, has recently been refuted by Royals²⁸ and Haag and Pines²⁹. Reaction 14 in fact only forms 44 per cent of the 1-olefin, the rest being 4-methyl pent-2-ene. Similarly the pyrolysis of 2-butyl acetate yields 1-butene (60 per cent) and 2-butene (40 per cent):

Isopropyl chloroformate pyrolyses by two processes³⁰, one of which forms hydrochloric acid, carbon dioxide and propylene. A type II reaction is obviously occurring:

but the conclusion should be treated with caution as ethyl chloroformate does not appear to decompose in this way³¹.

These various reactions have been extensively studied because the products from pyrolysis are stable at the temperatures of decomposition. With ketones and other carbonyl compounds which may form an olefin and a lower member of the same series, this is not so, for the smaller fragment will decompose too.

As on photolysis (reaction 10), acetic anhydride pyrolyses to form ketene. The molecular nature of this decomposition has been shown by the absence of dibenzyl among the products when Swarc and Murawski studied it, using the toluene carrier gas method³².

Some sealed-tube experiments with *n*-butyric acid and its methyl ester showed that here too the reaction is present. Ethylene formed a large proportion of the products with butyric acid at 550° C., while it was almost the only non-condensable product from methyl butyrate:

The activation energy for this reaction is approximately 34 kilocalories/mole.

The thermal decomposition of these compounds resembles the photochemical reactions. The type II split, which is intramolecular, is the low-temperature form of decomposition, while if the temperature is raised considerably, free-radical products are formed which are consistent with 'type I' reactions.

Electron Impact Studies

The widespread use of the mass spectrometer for analysis has necessitated the tabulation of large amounts of data on a variety of compounds. Sharkey and his collaborators³³ have studied rearrangement peaks in ketones: one significant group is formed by the scission of the β bond to the carbonyl group to form a charged lower ketone. The disadvantage of mass spectral studies is that only one fragment is generally detectable, the other being uncharged, but even so these results are important. Methyl *n*-propyl ketone and higher methyl ketones show a rearrangement peak at mass 58, probably formed by the reaction:

An analogy to the photochemical results is provided by the absence of a peak at mass 58 with methyl *isopropyl* ketone. Similarly 3-hexanone and larger ethyl ketones form a peak at mass 72 corresponding to the methyl ethyl ketone ion, and *isopropyl* ketones show a re-arrangement peak at mass 86 which corresponds to the methyl *isopropyl* ketone ion. Apparently the molecule splits into an olefin and a charged ketone.

Happ and Stewart, in an earlier investigation of the carboxylic acids³⁴, noticed a similar effect with *n*-butyric and the isomeric valeric acids which give peaks at mass 60, not formed by the lower acids or *isobutyric* acid. When carbon-13 was substituted into the carboxyl group the peak moved to mass 61, showing that the carboxyl group is present in the ion:

Although there have been no other suitable systematic studies, some data are available from the American Petroleum Institute lists³⁵. *n*-Butyraldehyde shows

a large peak at mass 44 as does 3-methyl butyraldehyde, which is not present with isobutyraldehyde.

Methyl butyrate forms a peak at mass 74 corresponding to the methyl acetate ion, which may be formed in a similar manner.

Esters with a large group in the 'alcohol' position (for example, ethyl acetate) form no significant peaks corresponding to the acid fragment, and any olefin is usually in a region already occupied by type I residues. Some information is provided, however, by chloro- and bromo-ethyl acetates. Chloroethyl acetate forms a peak at mass 62, corresponding to the chloroethylene ion, while bromoethyl acetate shows peaks at masses 106 and 108, consistent with the formation of bromoethylene from the two bromine isotopes:

These esters also do not show peaks corresponding to the acid ion, and it seems that fragmentation may take place in two ways depending on the presence of oxygen in the chain.

Although it is not possible to detect both of the fragments from electron impact, there seems ample evidence for a type II reaction here.

Radiolysis

In this comparatively new field there has been little interest in the molecules under consideration here. Some aldehydes have been examined but none which might give a type II reaction. However, Ausloos²⁶ has performed some experiments on ketones and has recorded that ethylene and propylene form a significant proportion of the products when methyl propyl ketone and methyl butyl ketone are radiolysed. Although nothing else has been examined, it is interesting to note that here, too, there is evidence of a type II split.

Mechanism of Rearrangement

It is clear that there is a form of decomposition occurring with these large carbonyl compounds, which is virtually independent of environment and conditions, and forms molecular products in a specific manner. For the reaction to be independent of the α and β groups, to break the β bond and to transfer a hydrogen atom from the γ - to the α -carbon atom requires a specific configuration. The most probable mechanism involves the formation of a six-membered ring as an intermediate and the separation of molecular products. This possibility was first put forward by Hurd and Blunk²¹ in 1938 for the pyrolysis of esters:

For this mechanism to occur with a ketone, say, on photolysis, an enol would be formed which must isomerize.

Srinivasan²⁷ has shown by his elegant isotopic work that this enol is indeed formed and isomerizes by exchange at the wall of the reaction vessel.

The cyclic intermediate explains the minimum size of the molecules required for this reaction, and provides an explanation for *n*-propyl substituents on the carbonyl group giving type II products while isopropyl derivatives do not. The advantage of the cyclic configuration over a flow of protons along the chain, which has also been suggested, is that it is independent of the α and β groups, which may be oxygen or carbonyl. The presence of an additional carbonyl group, as in acetic anhydride, would cause greater strain in the ring, but considering the activation energy required for this approximately thermoneutral reaction, and the transient nature of the intermediate, it should present no difficulty. Barton's work on the pyrolysis of (-) menthyl benzoate²⁸ is consistent with the ring: there are two positions in which *cis* elimination may occur from the terpene ring:

II is the only conformation available for the formation of menth-3-ene but there is an alternative *trans* linkage to I, which may be preferably formed. Consequently, when elimination occurs, there should be a greater proportion of *p*-menth-3-ene.

The work of Haag and Pines²⁹ on the pyrolysis of 2-butyl acetate (reaction 15) provides additional evidence, for again there are two possible intermediates:

In the case of III, which would form 1-butene, there are three hydrogen atoms available for transfer, while with IV there are only two to form 2-butene. Therefore, the yields of 1- and 2-butene should be in the ratio 3:2, as in fact is found.

Electronic States of the Larger Carbonyl Compounds

From the previous considerations, it is possible to assign some electronically excited states to these compounds, utilizing the Wigner spin conservation

rule and the results obtained in the photosensitized reactions of several of these compounds. In the mercury photosensitized decomposition of *n*-butyric acid, methyl butyrate, and *n*-butyraldehyde, type I products are formed, but there is no evidence of any intramolecular type II split¹⁴.

There are two established electronic states in the carbonyl compounds, the ground-state and the first excited state. The ground-state is necessarily singlet, as is the upper state formed on absorption of radiation, which raises an electron from a non-bonding orbital localized near the oxygen atom to a less localized antibonding orbital. The transition, designated $n \rightarrow \pi^*$, is forbidden by local symmetry³⁶. It is Mulliken's view that the upper state is not repulsive³⁷, and that photochemical dissociation takes place from other states reached by internal transition. The ground and excited states will be designated here as ^1M and $^1M^*$ respectively.

The type II reaction forms molecular products on photolysis through a mechanism which is independent of temperature or environment, and if spin is conserved the excited repulsive state must be singlet to give rise to singlet products. Although it is possible to postulate a triplet state forming a singlet olefin and a triplet ketone (or vice versa) it is known that triplet ethylene decomposes to form acetylene⁴⁰, while it is demonstrated below that triplet carbonyl compounds decompose to type I free-radical products. As it seems unlikely that the singlet 'type II' state is the vibrationally excited ground-state, for this would not be independent of phase and temperature, or the upper $^1M^*$ state, for no type I products would be formed, a separate singlet state ($^1M^{**}$) may be postulated.

The type I free-radical products may be formed from a singlet or a triplet state and the photosensitized results provide a means of distinguishing between the possibilities, for if spin is conserved then the reaction with excited mercury forms a triplet state ($^3M^*$):

The triplet state gives doublet free-radical products and it seems likely that it does so directly, rather than by internal conversion when type II products would also be formed.

These various conclusions may be conveniently summarized by means of a diagram (Fig. 1), where ethyl acetate is taken as an example. On photochemical excitation, $^1M^*$ state is formed, which gives rise to $^3M^*$ and $^1M^{**}$ states by internal conversion, forming type I and II products. On photosensitization the $^3M^*$ state alone is produced and forms free-radical products directly. Thermal decomposition is brought about by a molecule traversing point A from ^1M to $^1M^{**}$ to form type II products, while at higher temperatures the likelihood of crossing is increased and free-radical products are formed. Both electron impact and radiolysis obviously form the upper $^1M^*$ state, which in turn gives rise to type I and II reactions.

By consideration of spin alone, the transition time from the $^1M^*$ to the $^1M^{**}$ state should be faster than that for the $^1M^*$ to the $^3M^*$, and one would expect only type II products to be formed on photolysis. However, the $^1M^{**}$ requires a specific cyclic configuration and the time to form this may well be comparable

Fig. 1. Potential energy diagram for ethyl acetate

to that for spin reversal. In the photolysis of *n*-butyric acid¹⁴ where the quantum yield is less than unity, it was found that added oxygen increased the yield of type I products while the type II yield decreased slightly. The collision of a free radical, such as oxygen, with the upper excited state might catalyse spin reversal to form a $^3M^*$ state decreasing the number of molecules lost to the ground-state by internal transition and also decreasing the number available for conversion to the $^1M^{**}$ (type II) state.

Although it has been possible to deduce something of the nature of the excited states in these carbonyl compounds, more work is required before their identities are finally settled. The effects of oxygen and other free radicals should provide some useful results, and a correlation of this work and that on the fluorescence of lower ketones may prove fruitful. The thermal decomposition, which is first order, may provide a needed addition to the available examples of unimolecular reactions and it would be useful to study the kinetics at low initial pressures. The change in electronic state in the thermal reaction may be of some theoretical interest.

I wish to express my thanks to Prof. R. G. W. Norrish for many encouraging discussions and to the Department of Scientific and Industrial Research for the award of a maintenance grant.

SYNTHESIS OF MACROMOLECULES UNDER POSSIBLE PRIMEVAL EARTH CONDITIONS

By A. T. WILSON

Victoria University of Wellington, P.O. Box 196, Wellington, New Zealand

OPARIN¹ and Urey² have suggested that the primeval atmosphere consisted principally of methane with small amounts of ammonia and water vapour. Miller³ has shown that when a high-frequency Tesla coil discharge is passed through such an atmosphere, a multitude of organic molecules are produced, including amino-acids. This demonstration of the production of amino-acids has been received with great interest by all those interested in the origin of life, because of their simple chemical relationship to protein material, which seems to hold a key position in present-day life processes. The next step in the sequence of chemical evolution is the production of macromolecules from these simple chemical substances. It is not possible, under ordinary conditions, for the amino-acids to join up spontaneously to form proteins, since the thermodynamic equilibrium is very much in the direction of amino-acids. Fox⁴, however, has shown that polypeptides can be made under high temperature (160° C.) and anhydrous conditions. The work described in this communication shows how it would have been possible for macromolecules to have been produced on the primeval Earth.

The apparatus used (Fig. 1) is a 3-l. 'Pyrex' flask with tungsten electrodes sealed through the walls. A mixture similar to the composition which may have existed in the primeval ocean was made up thus: 10 gm. of baker's yeast was ashed at 600° C. and the ash dissolved in 100 c.c. water. Enough concentrated ammonia solution was added to make the solution 1 per cent in ammonia. A stream of hydrogen sulphide was then bubbled through the

solution for 10 min. The resulting solution was then placed in the apparatus, evacuated and filled with methane to a pressure of 1 atmosphere. The output of a 40-kV. 50 c./s. transformer was then connected to the two electrodes. The voltage was controlled by a 'Variac' on the transformer primary winding and adjusted to be just below the arcignp oint (approx. 20 kV.). It was difficult to measure the power dissipated in the reaction vessel, but, from the voltage drop across a resistor in the secondary circuit, it was estimated to be of the order of 5 W. At first, after running for 1 hr., a surface-active material was produced, demonstrable by shaking the vessel to produce a foam. After 4 hr., an insoluble transparent film had formed on the liquid-gas interfaces. This material (see Fig. 2) can be produced in more than 10 per cent yield (based on methane). It is insoluble in organic solvents (for example, methyl alcohol, ethyl acetate, acetone, ethyl ether, hexane, benzene and carbon tetrachloride). It is infusible up to 400° C., and at this temperature slowly decomposes. On analysis, this material is found to have the composition C = 75.55, H = 7.33, N = 1.62, S = 0, ash = 3.79 per cent. The infra-red analysis is that of a highly cross-linked polyethylene-type structure with the presence of C=O bands. It has been found that this material will take dyes (for

Fig. 1

Fig. 2

example, methylene blue and fuchsin), is hydrophilic and more dense than water. (If the ammonia and hydrogen sulphide are omitted from the experiment, a product is obtained which is hydrophobic and cannot be dyed.)

The liquid in the flask was turbid, and when it was examined under the electron microscope, sheet-like molecules were observed (Figs. 3 and 4).

Under the conditions of the experiment, large sheet-like structures are produced. These range in size from large fragments (Fig. 2) through smaller material (Fig. 3) to very small structures (Fig. 4) which are, in fact, macromolecules. The analysis and determination of properties were carried out only on the larger material (Fig. 2), although it might be assumed that this is a reasonable approximation to composition of the material seen under the electron microscope. Thus, high molecular weight polymer is produced from methane, water and ammonia under the influence of an electrical discharge. The combustion results, infra-red spectra and general properties suggest that this polymer is essentially hydrocarbon in nature, and that its surface is covered with polar groups which enable it to be dyed and impart its hydrophilic character.

It seems at first surprising that it is possible to proceed from a simple one-carbon molecule (methane) to what is a product of very high molecular weight. One might expect larger and larger molecules to be built up until the products were no longer volatile, at which stage they would condense out as a liquid. Gas chromatographic analysis of the residual gas in the flask shows that a complicated mixture of $C_1 \rightarrow C_5$ compounds is indeed produced. However, it is difficult to understand how molecules larger than C_{20} could be synthesized without their precursors condensing out. Thus, a liquid product might be expected rather than a solid of very high molecular weight. I suggest that the electrical discharge produces surface-active molecules which form films on the gas-liquid surfaces. These molecules become cross-linked together either directly by the corona discharge itself or by atomic hydrogen produced in the discharge. This mechanism might be expected to produce large sheet-like molecules with one side polar and the other side non-polar. Experiments are in progress to produce similar sheet-like molecules from surface-active materials directly.

If one assumes that the primeval atmosphere of the Earth consisted largely of methane with smaller

Fig. 4

amounts of ammonia², it is reasonable to suggest on the basis of the above experiment that large quantities of hydrocarbons of high molecular weight with surface polar groups could have been synthesized during electrical disturbances on the surface of the primeval ocean and even perhaps on cloud and rain droplets caught in the corona discharge of thunderstorms. This no longer takes place on the Earth because it now has an oxidizing atmosphere, but perhaps it is taking place on the larger planets which still have reducing atmospheres. When one considers the very large number of polar groups of many different kinds all randomly orientated to each other, would it be possible that some of these groupings might be of the right kind and of the right geometrical orientation to endow the macromolecule with 'enzymatic' activity? (The possibility of completely covering a cloud droplet with this material offers the possibility of having regions within the primeval ocean isolated by a membrane.)

Thus it is suggested that the early steps in the chemical evolution of life may have been based on catalysts or 'protoenzymes' in which the catalytic groupings were supported on material of hydrocarbon type. This 'hydrocarbon life' would then have evolved until it was sufficiently developed to be able to synthesize its own macromolecules, namely, protein, thus producing the beginning of our present-day 'protein life', where the catalytic groups of the enzymes are supported on protein material. Perhaps the petroleum and shale deposits in the Earth are the debris from the degradation of this material. (If, for example, these proto-enzymes attacked only polar groups and the process of degradation could not progress along the chain past a branch, the residue would be predominantly straight-chain hydrocarbons as are found in petroleum.)

The ease with which this material is produced would lead one to suppose that similar organic material of high molecular weight may be of frequent occurrence in unoxidized cosmic matter and, indeed, organic material of high molecular weight has been found in meteorites⁵. Do the clouds of Venus contain this material? In this connexion it is interesting to suggest that the fluorescent material⁶ found on the surface of the Moon is organic in nature. Also the

Fig. 3

gas observed by Kosyrev erupting in Alphonsus⁷ (a crater on the Moon) might be explained by the thermal cracking of lunar organic material by radioactive heating.

I wish to thank Dr. A. D. Campbell, of the University of Otago, for the combustion data, the Dominion Laboratory for the gas chromatographic and the infra-red analysis, the staff of the Electron Microscope Section, Dominion Physical Laboratory, for their kind co-operation, and Mr. F. B. Knox for interesting discussions. Much of this work was

carried out in the Institute of Nuclear Science, Lower Hutt, New Zealand.

PERCEPTION OF DISTANCE IN ANIMAL ECHO-LOCATION

By JAN NORDMARK

5 Bågvägen, Lidingö, Sweden

SINCE Griffin and Galambos¹ in 1940 discovered that bats orientate themselves by listening to the echoes from their own sounds, much information has accumulated about echo-location in bats and other animals². Thanks to a number of studies in this field, we now have a fairly extensive knowledge of the acoustical properties of such sounds. There are, however, many questions raised by these studies which have so far received no satisfactory answer.

How, for example, can a bat separate the faint echoes of its own sounds—short, ultrasonic pulses of high intensity—from those emitted at the same time by hundreds or more of other bats? How can they detect and capture an insect when echoes from the ground and countless objects must be returned also? What is the reason for the failure of various attempts to interfere with the echo-locating process, such as trying to jam bats by means of intense noise covering the frequency-range of their pulses³?

All efforts to give an answer to these questions are likely to be fruitless while we are uncertain which properties of the echoes the animals utilize in judging distance. Is it the time interval between outgoing pulses and returning echoes or the intensity of the echo or some other property that varies with distance? Whatever the essential property, it is difficult to understand how bats and other echo-locating animals can make any use of the information in the echoes, bearing in mind that the time interval between pulse and echo is of the order of a few milliseconds.

There are, however, some findings from studies in human auditory perception that may help us to get an idea of the mechanism of echo-location. A few years ago Thurlow and Small⁴ discovered that two pulse trains of identical repetition rate but slightly separated in time gave rise to a tone the pitch of which corresponded to the magnitude of the time separation. For example, if one train of pulses has a repetition rate of 100 per sec. and a second identical pulse train follows in 1/400th of a sec., the time separation pitch is that of a 400-c.p.s. tone. Decreasing the time separation gradually produces a tone that sweeps upwards (the authors call this phenomenon sweep pitch). Increasing the time separation makes the tone sweep downwards until the difference is half the pulse interval, when the time-difference pitch is the octave of the pulse-repetition frequency, 200 c.p.s. in the above example. A further increase of the time

separation makes the tone increase in pitch again. The time-difference pitch thus always corresponds to the shorter time separation. One of the pulse trains may be considerably less intense than the other, particularly if the time separation is small⁵. At a sensation-level of 30 decibels the less-intense pulse train had to be reduced about 17 decibels before the effect disappeared.

There seems to be no reason why bats and porpoises should be different from us in this respect. They will consequently hear a tone the pitch of which corresponds to the time separation between the outgoing pulses and returning echoes, provided the echoes are not too weak. It is tempting to assume that they are also guided in their orientation by these very tones.

If this interpretation is correct, tones in a certain frequency-range have to them acquired a meaning of distance, so that, for example, a rising pitch signifies shrinking distance. If we take into consideration the fact that the echo will return slightly earlier if the animal is moving (although this will affect the result very slightly), a formula expressing the relations involved will be as follows:

$$f = \frac{c + v}{2s}$$

where f is the frequency in c.p.s. that corresponds to the perceived pitch, c and v are the velocity in cm./sec. in the medium (air or water) of sound and animal, respectively, and s is the distance in cm. from the animal's mouth to the object at the moment when the pulse is emitted.

A particularly attractive feature of this mechanism is that the rate of change of pitch is greater close to the object, where the need of accuracy is most acute. As a bat moves from 175 to within 155 cm. of an object, the pitch change will be from about 100–113 c.p.s., whereas an equal change of distance from 40–20 cm. will cause a rise of pitch from about 440–880 c.p.s.

As the lowest audible time-difference tone is unlikely to be much lower than 100 c.p.s., 2–3 metres is probably the greatest distance at which a bat can detect an object by this technique, the corresponding distance for animals living in water being 9–15 metres. This could explain why bats never give any signs in the form of increased pulse rate to show that they

have detected even large objects, such as walls, until they have come within this range. As also thin wires and other objects can be detected at a comparable distance it is possible that some factor other than the intensity of the echoes puts a limit to the distance of detection. Some puzzling results from experiments on a bat's ability to detect wires of different sizes strung across a room may be interpreted in this light. Increasing the size of the wires made the bats show signs of reacting at an increasingly greater distance. As the wire is increased from 1 to 3 mm., however, the distance of detection changes from just less than 2 to not more than about 2.25 metres, which is much less than would be expected¹. One of the possible explanations for these observations given by the authors is that the bats detect the objects at a greater distance than their data indicate, but do not trouble themselves to increase the pulse rate until they come within a metre or two. For reasons already stated, however, it is possible that they cannot detect objects beyond a certain distance regardless of the strength of the echoes.

We are probably justified in assuming that the time-difference tone can be heard only as a result of a recurrent or a gradually changing pattern, although this aspect of the problem has not been investigated. Every time the animal approaching an object emits a pulse, the time-interval between pulse and echo will be slightly shorter, but the change will be a gradual one. This explains how an echo can be sorted out from among a large number of pulses, such as those from other animals. There is an infinitesimal chance that any two animals' pulses will have exactly the same repetition rate with a constant or gradually changing displacement in time, which are the necessary conditions for a time-difference tone. The pulse rate, moreover, is never absolutely constant, as Griffin's records for the bat *Eptesicus* show, but is slightly irregular even when the mean rate is nearly constant. This is of no consequence for the time-difference tone but makes the animal even less susceptible to interference from other pulses.

There is, however, every reason to believe that echoes from objects at different distances can each give rise to a separate tone, if the relation between pulse and echo is constant. As the pulse repetition rate is never exactly constant, a series of echoes the time lag of which exceeds one pulse-interval can produce no regular pattern and consequently no tone. The same reasoning can be applied to a series of echoes returning in the second half of the pulse interval. The echo will be too far removed from the original pulse, if the findings of Thurlow and Small are applicable under these conditions, and the relation to the next pulse will not be sufficiently constant.

Objects beyond a certain distance depending on the pulse rate can therefore not be detected, at least not by this method. This is probably the reason for the increase in rate as an animal starts to approach an object. As the rate goes up, the zone from which objects return echoes capable of producing a time-difference tone shrinks. At the maximum rate recorded, 200 per sec., a bat would thus not be able to detect anything beyond a distance of about 43 cm. A similar result may be obtained by emitting pulses of gradually reduced intensity or by a combination of both methods.

In this way the porpoise and many types of bats have at their disposal a means of increasing the acuity of their perception analogues to visual accommodation. Another way of excluding irrelevant

echoes is to concentrate the emitted sound into a narrow beam. This method is used by some members of the family Rhinolophidae, which thereby compensate for a relatively low maximum repetition rate.

In the calculations above it has been tacitly assumed that the pulse is of negligible duration, and this is not strictly speaking correct. The calculations will scarcely be affected all the same, as Thurlow and Small have shown that the time-difference tone could be heard even when there was an overlap between the pulse trains. It is probably the time difference between the peaks of the sound pressure that determines the pitch. This conclusion is supported by observations recently made by me on pure tones bearing a simple mathematical relationship to one another, such as 1:2, 2:3, 1:3. Varying the phase of one of the tones produces, under certain conditions, a weak time-difference tone the pitch of which corresponds to the time separation between the closest peaks of the sine waves.

Perhaps the most baffling of all problems connected with echo-location has been how bats can discern the faint echoes from thin wires well enough to avoid them even in the presence of thermal noise of much higher intensity. As Thurlow and Small state that they were not able to obtain these tones when thermal noise of various intensities was presented simultaneously with the pulses, this might seem to be a serious objection to my hypothesis.

It is important to note, however, that these experiments were conducted at the relatively low sensation level of 30 decibels, whereas the sound pressure level of the pulses of bats often exceed 100 decibels. I have therefore investigated the effect of thermal noise on pulses of high intensity. The outputs of two pulse generators were led through a narrow band-pass filter and mixed with thermal noise. When the pulses had an intensity of 90 decibels r.m.s. the time-difference tone was clearly audible even when the intensity of one of the pulse generators was considerably reduced and that of the noise was at intermediate level.

Further investigation of the phenomena which have a bearing on the problem of echo-location in relation to rate, composition, and intensity of pulses and echoes is clearly needed. The pulse rate of bats is often only 10 per sec. or even lower, whereas the lowest rate tried on human beings is 25 per sec., when the tone sounded similar to pure tones of short duration⁴.

The hypothesis outlined here seems compatible with the acoustical properties of sound produced by many different types of bats, as they are set forth in great detail in a recent paper by Novick⁵. It enables us to understand how these animals can achieve a high degree of precision in their orientation without any corresponding degree of precision in the sound production. The frequency composition, duration, intensity and regularity of the pulses from animals of different types and from one single animal can and do vary within wide limits without serious consequences. Far from being a shortcoming, the irregularity is often, as we have seen, an advantage.

A SIALOMUCOPEPTIDE LIBERATED BY TRYPSIN FROM THE HUMAN ERYTHROCYTE

By G. M. W. COOK, DR. D. H. HEARD and DR. G. V. F. SEAMAN*

Department of Radiotherapeutics, University of Cambridge

DURING the course of a microanalytical examination of the action of trypsin on the surface of the saline-washed human erythrocyte it was found that a sialomucopeptide was liberated by this enzyme.

Ponder¹ has observed a decrease in the electrophoretic mobility of the erythrocyte on treatment with trypsin. The reduction in mobility corresponds to about a 20 per cent decrease in the net negative surface charge density and is accompanied by an increase in volume of the erythrocyte. Pondman and Mastenbroek² suggested from analytical evidence that there is a loss of phospholipid from the erythrocyte on treatment with trypsin. Seaman and Heard³ were unable to confirm this finding, and suggested that the decrease in mobility is the result of a diminution in the number of α -carboxyl groups effective at the electrophoretic plane of shear.

Trypsin is known to inactivate most mucoproteins which inhibit influenza virus haemagglutination. Since sialidase inactivates all such inhibitory mucoproteins, presumably by the release of sialic acid⁴, trypsin could therefore also release a bound sialic acid. Klenk⁵ has demonstrated the presence of a sialic acid (N-acetylneuraminic acid) in the stroma of human erythrocytes.

Standard washed human erythrocytes⁶, of phenotypes A Rh +ve, B Rh +ve, ORh +ve and -ve and AB Rh -ve, were examined. 10 c.e. of packed cells per experiment were treated with trypsin (50 μ gm./ml.) according to a modification of the method of Morton and Pickles⁷. Appropriately controlled erythrocyte supernatants from each experiment were deproteinized with 20 per cent w/v aqueous trichloroacetic acid, filtered through a No. 50 Whatman paper, reduced to small volume at 50°C. under reduced pressure and the trichloroacetic acid extracted with diethyl ether. The aqueous phase was again reduced in volume and desalted electrolytically.

Finally, these processed supernatants were reduced to dryness and the residues taken up in a few drops of 10 per cent v/v aqueous isopropanol. These solutions were examined by descending paper chromatography (Whatman No. 1 paper, butan-1-ol : acetic acid : water (4 : 1 : 5) organic phase). The air-dried chromatograms were dipped in 0.2 per cent w/v ninhydrin in acetone and developed at 90°C.

* Beit Memorial Research Fellow.

Fig. 1 shows schematically the appearance of a ninhydrin-positive compound (purple complex) of R_F 0.65, designated compound 1, from the supernatant of trypsin-treated red cells. This compound is not present in any of the controls. Fig. 2 is a photostat copy of a chromatogram showing components as in strip 1 and strip 5 of Fig. 1.

Compound 1 was eluted with 10 per cent v/v aqueous isopropanol from an air-dried untreated controlled chromatogram. The ultra-violet absorption spectrum of eluates of compound 1 shows absorption over the wave-lengths 215–300 m μ with a minor peak at about 270 m μ . Acid treatment of compound 1 produces an increase in the absorption over the range 270–290 m μ (see Fig. 3) and on alkaline treatment there is an increase at 260 m μ (Fig. 4). This spectral behaviour does not suggest trichloroacetic acid contamination and is characteristic of materials containing sialic acid⁸.

Microchemical estimations were performed on solutions of compound 1 in 10 per cent v/v aqueous isopropanol. The nitrogen content of the eluates was determined colorimetrically by the Nessler method of Johnson⁹ and the carbohydrate content was assayed using an anthrone reagent¹⁰. Sialic acids were determined colorimetrically by the resorcinol-hydrochloric acid method of Svennerholm¹¹ and the 2-thiobarbituric acid technique of Warren¹². It was

Fig. 1. Map showing regions of ninhydrin-positive material on the chromatograms. Strip 1, supernatant from trypsin-treated human erythrocytes (conc. 50 μ gm./ml. total of 2 mgm. trypsin); strip 2, autolysis of trypsin (conc. 50 μ gm./ml. total of 2 mgm. trypsin); strip 3, impurities in trypsin (total of 25 mgm. trypsin); strips 4 and 5, supernatants from normal human erythrocytes; (4) incubated in saline (vol. of saline = vol. of saline in strip 1 experiment); (5) supernatant obtained as in strip 4, re-incubated with trypsin (conc. = 50 μ gm./ml.). Electrophoretic mobility of untreated erythrocytes = $2.78 \pm 0.08 \mu \text{ sec.}^{-1} \text{ V.}^{-1} \text{ cm.}$ Electrophoretic mobility of trypsin-treated erythrocytes = $2.30 \pm 0.06 \mu \text{ sec.}^{-1} \text{ V.}^{-1} \text{ cm.}$

Fig. 2. Photostat copy of chromatograms developed with ninhydrin, from experiments strip 1 and strip 5. Compound 1 present only in experiment strip 1

Fig. 3. Ultra-violet absorption spectra in 10 per cent v/v aqueous isopropanol of: ●, eluate containing compound 1 (sialic acid content, 1 $\mu\text{gm./ml.}$, pH 6.1; ■, eluate containing compound 1 (sialic acid content, 1 $\mu\text{gm./ml.}$) after heating for 10 min. at 90°C., pH 2.8; ▲, trichloroacetic acid solution (1,000 $\mu\text{gm./ml.}$, pH 2.0

Fig. 4. Ultra-violet absorption spectra in 10 per cent v/v aqueous isopropanol of: ▲, eluate containing compound 1 (sialic acid content, 16 $\mu\text{gm.}$ in 5 ml.), pH 5.1; ■, above material reduced to dryness and treated with *N* sodium hydroxide (0.075 ml.) at 105°C. for 17 hr., dissolved in water (5 ml.) adjusted with hydrochloric acid to pH 5.8; ●, 2 carboxy-pyrrole (1 $\mu\text{gm./ml.}$, pH 4.9

found that in compound 1 the ratio of nitrogen to carbohydrate (as glucose) to *N*-acetylneuraminic acid (after treatment with 0.1 *N* sulphuric acid at 80°C. for 1 hr.) was as 18:10:1 by weight. The high nitrogen content coupled with the appearance of a purple complex with ninhydrin is indicative of a peptide character for compound 1, which would be expected from the known specificity of trypsin. The release from the periphery of the erythrocyte membrane of this sialomucoprotein, probably structurally analogous to that suggested for ovine submaxillary gland mucoprotein by Gottschalk¹³, could account for the decrease in electrophoretic mobility of the erythrocyte observed after treatment with trypsin.

We wish to thank the Medical Research Council for financial assistance, Prof. D. D. Eley and Prof. J. S. Mitchell for useful discussion and Mr. E. W. Mitchell for the photography.

PHYSICS

Use of an Artificial Satellite to test the Clock 'Paradox' and General Relativity

An interesting and promising test for the effects of gravitation and motion on the relative rates of a satellite clock and an earthbound clock was proposed four years ago by S. F. Singer¹. For this purpose Singer used the Schwarzschild metric for the Earth's field and considered a circular satellite orbit. The neglect of the ellipticity of the Earth has been justified by B. Hoffmann², provided that the mean radius is used. Neglecting also the rotatory motion of the Earth clock Singer found for the red shift of the satellite clock relative to the Earth clock the expression:

$$\Delta = \frac{dt_S - dt_E}{dt_E} = \frac{\gamma M}{2c^2 R} \left(\frac{1 - 2h/R}{1 + h/R} \right) \quad (1)$$

where R is the radius of the Earth, M its mass, h the height of the satellite above the surface of the Earth, and γ and c have their usual meanings.

However, Singer's calculation is open to criticism, as is also the work of H. Nariai and Y. Ueno³, who calculate the result for an elliptic orbit following Singer's procedure, since the dt_S , dt_E here are the co-ordinate time-intervals corresponding to unit ticks of the respective clocks. Singer justifies this procedure on the ground that, since t measures proper time for an observer at rest at great distance from the Earth, Δ will therefore measure this observer's view of the relative rates. This is not so since we do not have flat space-time near the Earth where the clocks are. Furthermore, this expression for Δ is not invariant. If we performed a Lorentz transformation at infinity we should find a different value of Δ in terms of the new co-ordinate t' . Finally, we remark that the view of an observer at great distance is not relevant to the practical procedure which Singer suggests for carrying out the test, that is, to make a direct comparison by radio of the cumulative number of oscillations of the two clocks after a suitable number of revolutions of the satellite.

We shall obtain here an invariant form for the expression that Singer desired to measure. As it happens it agrees with Singer's result, but it appears difficult to justify Singer's method of analysis until implied assumptions are clarified. In view of past controversy over the clock paradox, and the need for tests of general relativity, it is thought that a different approach to Singer's test will be of interest.

We formulate in the first instance a slightly different problem from that proposed by Singer. Let a rocket, equipped with a caesium atomic clock, leave the Earth at a given point and ascend to a suitable height where it goes into free circular orbit about the Earth. Let the rocket complete a suitable number of revolutions and thereafter make a controlled descent to land at the same point of the Earth at which it started. Supposing that the times for ascent and descent are small compared with the time in orbit,

we wish to compare the cumulative number of oscillations of the rocket clock with the cumulative total on a similar clock at the rocket base on the Earth.

Following Singer we adopt the Schwarzschild metric for the Earth's field:

$$ds^2 = (1 - 2m/r)dt^2 - \frac{1}{c^2} \left\{ \frac{dr^2}{1 - 2m/r} - r^2 d\theta^2 - r^2 \sin^2 \theta d\phi^2 \right\} \quad (2)$$

in which $m = \gamma M/c^2$. If we put:

$$v^2 = \left(\frac{dr}{dt} \right)^2 / (1 - 2m/r) - r^2 \left(\frac{d\theta}{dt} \right)^2 - r^2 \sin^2 \theta \left(\frac{d\phi}{dt} \right)^2 \quad (3)$$

then the element of proper time as registered on the rocket clock will be:

$$ds_{\text{rocket}} = \left(1 - \frac{2m}{r} - \frac{v^2}{c^2} \right)^{\frac{1}{2}} dt \quad (4)$$

To adequate approximation v is the Newtonian velocity relative to the Earth. Let the orbit be characterized by $\theta = \pi/2$, $d\phi/dt = \omega$ (constant), $r = a$ (constant). Then the total proper time registered on the rocket clock during the whole journey will be:

$$[s]_{\text{rocket}} = \int_{t_1}^{t_2} \left(1 - \frac{2m}{a} - \frac{\omega^2 a^2}{c^2} \right)^{\frac{1}{2}} dt + \int_{t_0}^{t_1} \left(1 - \frac{2m}{r} - \frac{v^2}{c^2} \right)^{\frac{1}{2}} dt + \int_{t_2}^{t_3} \left(1 - \frac{2m}{r} - \frac{v^2}{c^2} \right)^{\frac{1}{2}} dt \quad (5)$$

where t_0 is the co-ordinate time of leaving base, t_1 the time of going into orbit, t_2 that of leaving orbit, and t_3 the co-ordinate time of landing at the base. In the last two integrals of (5) r and v will be functions of t .

Similarly, the total proper time registered on the base clock will be:

$$[s]_{\text{base}} = \int_{t_0}^{t_3} \left(1 - \frac{2m}{R} - \frac{V^2}{c^2} \right)^{\frac{1}{2}} dt \quad (6)$$

where V is the velocity of the base point arising from the Earth's rotation.

But $t_1 - t_0$, $t_3 - t_2$ can be made arbitrarily small compared with $t_2 - t_1$, and so we are able to take:

$$t_2 - t_1 \approx t_3 - t_0 \quad (7)$$

and neglect the last two integrals in (5). Furthermore, the geodesic equations of general relativity, as well as the Newtonian theory, yield:

$$\omega^2 a^2 = m c^2 \quad (8)$$

Hence, to sufficient approximation:

$$[s]_{\text{rocket}} \approx \left(1 - \frac{3m}{2a} \right) (t_2 - t_0) \quad (9)$$

and since $V^2 \ll \omega^2 a^2$ for a satellite orbit :

$$[s]_{\text{base}} \simeq \left(1 - \frac{m}{R}\right) (t_3 - t_0) \quad (10)$$

Therefore, the invariant fractional excess of the registered time on the Earth clock over that registered on the rocket clock is :

$$\frac{[s]_{\text{base}} - [s]_{\text{rocket}}}{[s]_{\text{rocket}}} \simeq m \left(\frac{3}{2a} - \frac{1}{R} \right) \quad (11)$$

which, if $a = R + h$, is :

$$\frac{\gamma M}{2c^2 R} \left(\frac{1 - 2h/R}{1 + h/R} \right) \quad (12)$$

This result has the same interpretation as Singer's. That is, the rocket clock registers the smaller time if $h < \frac{1}{2}R$, and the greater time if $h > \frac{1}{2}R$, or a net red shift and violet shift respectively of order 1 c./s. of the caesium line.

We could, of course, avoid the necessity of a relatively short period of ascent and descent by requesting the satellite to telemeter its 'readings' for comparison with the base clock from the time of going into orbit to the time of completing a suitable number of circuits, as suggested by Singer. Our result (11) would still apply. But to emphasize that this is a test of the familiar clock paradox, or problem of identical twins, we have chosen to reunite the two clocks at the same space-time event.

In so far as we have deduced the result from the Schwarzschild metric it is also a test of general relativity, that is, of the curvature of space-time that general relativity predicts for the case of a spherical mass.

More strictly, this experiment tests that part of general relativity usually referred to as the principle of equivalence, together with certain features of the Schwarzschild metric which might have been predicted from Newtonian gravitation, in agreement with a view of the Schwarzschild metric recently expressed by H. Bondi and C. W. Kilmister⁴.

⁴ Bondi, H., and Kilmister, C. W., *Amer. J. Phys.*, **28**, 508 (1960).

DR. DAVIDSON is quite right in remarking that it is not necessary to introduce an observer at great distance from the Earth in order to measure proper time. But neither is it necessary to bring the two clocks into space-time coincidence at the beginning and at the end of the experiment, as he has done in his derivation. In fact, the experimental method for doing the measurement requires only a comparison of the time intervals necessary to accumulate a large number of ticks on the two clocks, and this comparison could be done by any third observer.

What is interesting is the fact that our derivations do give the same result, as does the derivation superimposing the simple 'red shift' and second-order Doppler shift (from the special theory of relativity). This agreement is not accidental, as Davidson implies. It depends on the fact that the observer at a great distance from the Earth does not carry out any

irregular motion; hence his introduction appears to be correct and entirely equivalent to having, for example, the Earth clock signals themselves determine the co-ordinate time. The reason for this is that the signals travel along null geodesics in a time-independent metric.

I am indebted to my colleague Prof. J. Weber for useful discussion.

Theoretical Magnetic Moments of Proton and Neutron

RECENTLY it was shown that the equation :

$$E = 38.46 [l(l+1) + s(s+1)] \text{ MeV.} \quad (1)$$

provides a correlation of empirical particle masses¹ and of nucleon excitations².

The prediction of a resonance energy E_r at 750 MeV. in free protons has now been fully confirmed^{3,4}. The maximum for π^+ scattering reported to lie at 1.3 or 1.35 MeV.^{5,6} appears to be a doublet as can be seen from Table 1.

Table 1. CALCULATED AND OBSERVED RESONANCE ENERGIES (MEV.) FOR PHOTOPIONS AND FOR PION SCATTERING FROM HYDROGEN

Transitions	${}^2F_{1/2} \rightarrow {}^2F_{3/2}$	${}^2P_{1/2} \rightarrow {}^2P_{3/2}$	${}^2G_{3/2}$	${}^2D_{3/2}$	${}^2G_{1/2}$	${}^2D_{1/2}$	${}^2H_{3/2}$	${}^2F_{5/2}$
Pairs created	270	279	308	520	577	750	961	980
E_r calculated	270	279	308	520	577	750	961	980
E_r observed (cm.)	268	279	299	543	574	750	958	983.5
	$\gamma\pi^+$	$\gamma\pi^0$	$\pi^\pm$	$\gamma\pi^+$	$\pi^-\gamma\pi^0$	$\pi^-\gamma\pi^0$	π^+	π^+

This table gives the energies for the transitions from the core particle ${}^2F_{1/2}$ to the indicated higher levels, and the energies needed for the formation of pairs, all calculated according to equation (1). The last line of figures gives the observed resonance energies in photo-production and scattering of pions from free protons.

Equation (1) provides thus a numerical interpretation of all observed resonance energies. The agreement is in several cases within 1 per cent, less than the estimated error.

Equation (1) also contains quantum numbers which are essential for calculating the magnetic moments of the proton and the neutron. In particular, in Table 1, the state ${}^2F_{1/2}$ plays an important part as the core particle of the proton.

The anomalous magnetic moments of proton and neutron are generally believed to be caused by the contributions of charged (virtual) pions. The magnetic moment of the free pion, however, must be zero. The parity of the pion is odd. Thus it must possess an internal angular momentum, most probably $l = 1$. The correlated magnetic moment is compensated by the anomalous magnetic moment connected with the spin $s = \frac{1}{2}$ of the electric charge. Also the total angular momentum of the pion is zero.

Since the charged pion is required to contribute to the magnetic moment of the nucleon, it cannot be bound in an S-state.

The next simplest case is $l = 1$ for the pion orbital. Then the contribution of the pion to the magnetic moment is one pion magneton :

$$\mu_\pi = (m_p/m_\pi) \mu_0 = 6.72 \mu_0 \quad (2)$$

where μ_0 means one nuclear Bohr magneton and m_p and m_π are the rest masses of proton and pion respectively.

The core particle ${}^6F$ can be assumed to have total angular momentum $I = \frac{1}{2}$ as the ground-state because the system will have minimum energy if the total angular momentum has its minimum value, since then the energy due to the magnetic field connected with the angular momentum will be a minimum.

The ground state of the nucleon is $I = \frac{1}{2}$. The addition of a pion with orbital $l = 1$ to the state ${}^6F_{\frac{1}{2}}$ can lead again to a state with $I = \frac{1}{2}$ as required.

In the case of the neutron the core particle ${}^6F_{\frac{1}{2}}$ can exchange its positive charge with the bound negative pion, since the pion must contain two spins $s = \frac{1}{2}$ to compensate the internal angular momentum to zero. Therefore one spin $s = \frac{1}{2}$ is not occupied by charge.

The probabilities for finding the positive charge at the core or at the pion can be expected to be in the ratio:

$$(2I + 1) : (2l + 3) = 2 : 5 \quad (3)$$

counting for the statistical weight of the boson, $2 + 1 = 3$ for the bond orbital $l = 1$, another unit for the internal angular momentum $l = 1$ indicated by the odd parity of the pion, and another unit, the sum of the two spins $s = \frac{1}{2}$ which compensate the internal angular momentum of the pion to zero.

The magnetic moment μ_N of the neutron can thus be expected to be:

$$\mu_N = (2/7) \mu({}^6F_{\frac{1}{2}}) - (2/7) \mu_\pi \quad (4)$$

The magnetic moment of the core particle $\mu({}^6F_{\frac{1}{2}})$ is not known. The contribution $\mu(F)$ of the F -term ($l = 3$) has to be three core magnetons:

$$\mu(F) = 3(m_p/m_0) \mu_0 = 3.527 \mu_0 \quad (5)$$

The core mass m_0 of the state ${}^6F_{\frac{1}{2}}$ is given by equation (1).

Systems with rotational motions belonging to half-integral quantum numbers were investigated by Weyl⁶. In his case, the half-integral quantum numbers are due to the combination of an intrinsic spin $s = \frac{1}{2}$ and an integral quantum number of the type of angular momenta. The magnetic moment due to the spin $s = \frac{1}{2}$ is anomalous, namely, one full unit of a magneton. The quantum number $5/2$ should thus lead to three core magnetons and therefore to the same absolute value as given in equation (5). In the state ${}^6F_{\frac{1}{2}}$, however, the two contributions have opposite signs, thus:

$$\mu({}^6F_{\frac{1}{2}}) = 0 \quad (6)$$

Then, together with (4) and (2):

$$\mu_N = - (2/7)(m_p/m_\pi) \mu_0 = -1.92 \mu_0 \quad (7)$$

This value deviates by less than $\frac{1}{2}$ per cent from the empirical value $\mu_N = -1.913 \mu_0$. This small difference is probably caused by the relativistic increase of the mass of the pion owing to its kinetic energy.

The result of equation (7) justifies the assumptions made above and leads to the conclusion that the pion is not virtually created but permanently present, and in a well-defined state. The same conclusion was also reached from the mass difference of the nucleon and of the core particle¹.

In the case of the proton, the bound pion has to be neutral. This is the case if the two spins $s = \frac{1}{2}$ within the pion are occupied by opposite charges. Then there is no spin $s = \frac{1}{2}$ free of charge and the exchange of a single charge between core and pion which occurs within the neutron is no longer possible within the proton.

According to equation (1), however, there is the possibility of resonance between the isobaric states ${}^6F_{\frac{1}{2}}$ and ${}^6G_{7/2}$. The probabilities for finding the core particle in these states are in the ratio 2 : 8, due to the respective values of $2I + 1$.

Then the resulting magnetic moment of the core should be:

$$\mu_G = (0.2) \mu({}^6F_{\frac{1}{2}}) + (0.8) \mu({}^6G_{7/2}) \quad (8)$$

The magnetic moment of the state ${}^6G_{7/2}$ must be $4 - 1 = 3$ core magnetons, incidentally the same value as given in (5). This value together with (6) and (8) leads to:

$$\mu_G = (0.8)3(m_p/m_0) \mu_0 = 2.82 \mu_0 \quad (9)$$

This value deviates only about 1 per cent from the empirical value of the magnetic moment of the proton $\mu_p = 2.79 \mu_0$. The difference is presumably due to diamagnetism of the neutral pion contained in the proton.

In the resonance process between the isobaric states of the core, the total angular momentum would not be conserved. This condition can be fulfilled in the case of the proton if the angular momentum of the bound neutral pion changes from $l = 1$ with core ${}^6F_{\frac{1}{2}}$ to $l = -3$ with core ${}^6G_{7/2}$.

The neutral pion can be bound to the core by the exchange of the positive charge of the core and of the positive charge which neutralizes the negative charge in the neutral pion. This process would not change the magnetic moment of the system.

The resonance process within the proton between the two isobaric core states ${}^6F_{\frac{1}{2}}$ and ${}^6G_{7/2}$ introduces also an unsharpness of the two states and widens the energy range in which resonance can occur.

If the bound pion were not neutral, additional energy would be required to build up the magnetic field connected with the orbital $l = 3$. This would destroy the condition for resonance which exists for the system of core and bound neutral pion. In fact, the ensuing magnetic moment would also destroy the agreement with the empirical values.

Thus the resonance process between the isobaric states ${}^6F_{\frac{1}{2}}$ and ${}^6G_{7/2}$ appears to be possible only in the case of the proton with its neutral pion, but not for the neutron as a compound of a positive core and a negative pion. In this way one can understand the exceptional stability of the proton.

Like the proton, the Σ -particle appears to contain a neutral pion. The rest energy of the charged Σ -particle is 1,319 MeV., and this is quite near the sum of a ${}^6H_{9/2}$ particle and of a neutral pion, namely, $1,182 + 135 = 1,317$ MeV.

The agreement between calculated and empirical values of the magnetic moments of proton and neutron indicates that the half-integral quantum numbers s in equation (1) refer really to Weyl's relativistic system of spherical harmonics with spin.

The quantum numbers of equation (1) must belong to internal degrees of freedom of extended particles, and this equation appears now to be relevant to the calculation of the masses of the 'elementary'

heavy fermions, of the internal excitation energies of the free proton and of the magnetic moments of proton and neutron.

Generation of Water Waves by the Wind

THE spectral energy density ϕ of small deep-water waves increases with wind speed and fetch, for a given frequency-band, only up to a certain value. For larger wind speed or fetch the energy density appears to become saturated, as was noticed by Burling¹ and by Phillips². Having recently completed a detailed analysis of two sets^{1,3} of data on ϕ , I can now give quantitative evidence for this apparent saturation. (I am indebted to Dr. Burling and to the Imperial College of Science and Technology, London, for permission to use the original data published in his thesis.)

For the purposes of the analysis I assumed ϕ to be of the form:

$$\begin{aligned} \phi &= b_1 V r_1 F^{s_1} f^{t_1} & f \leq f_0 \\ &= b_2 V r_2 F^{s_2} f^{t_2} & f > f_0 \end{aligned} \quad (1)$$

where V , F , and f are the independent variables in the experiments, that is, the average wind speed, the average fetch, and the wave-frequency. The eight parameters, b_1 , b_2 , r_1 , r_2 , s_1 , s_2 , t_1 , and t_2 , are at our disposal in making the best fit to the experimental data. On the basis of earlier analyses we can expect that r_1 , s_1 , t_1 and $-t_2$ will be positive, the opposite signs of t_1 and t_2 , implying that the largest value of ϕ , for given V and F , is reached at $f = f_0$. The value of f_0 is given by the equation:

$$b_1 V r_1 F^{s_1} f_0^{t_1} = b_2 V r_2 F^{s_2} f_0^{t_2} \quad (2)$$

For a frequency $f < f_0$, the spectrum is unsaturated. For a frequency $f > f_0$, the spectrum is saturated with respect to increases of wind speed or fetch if the absolute values of r_2 and s_2 are small compared to one. (Phillips refers to the saturated part of a spectrum as the "equilibrium range".) More complete descriptions of wave generation than these equations afford would require the specification, for example, of the velocity profile above the water and the directional spectra of the wind and of the waves.

Burling's data consist of 463 measured values of ϕ for various combinations of frequency, average wind speed, and average fetch in the ranges:

$$0.4 \leq f \leq 1.8 \text{ c.p.s.}, \quad 5.0 \leq V \leq 8.8 \text{ m./sec.}, \\ \text{and } 400 \leq F \leq 1,350 \text{ m.}$$

All the wave systems that he studied were thus in the gravity wave regime. My data consist of 273 measurements of the wave energy, observed through octave-wide filters centred at 0.75, 1.5, 3, 6 and

12 c.p.s., for various combinations of average wind speed and average fetch in the ranges:

$$0.15 \leq V \leq 10.2 \text{ m./sec. and } 5 \leq F \leq 625 \text{ m.}$$

Most of the waves that I measured also were in the gravity wave regime. Integration of the function ϕ in equation (1) over the power transfer function of the filter yields energy values which can be compared with my experimentally determined values. For each of the two sets of data a least-squares fit was made to find the best values of the eight parameters in equation (1). Afterwards, 10 sub-sets of data were chosen at random from each set of data, and least-squares fits, starting with randomized values of each parameter, were made for each of the 20 sub-sets. I shall discuss here the results of my analysis only for the parameters r_2 , s_2 , t_1 , and b_2 .

In Table 1 are listed, for each set of data, the best values of these four parameters and the probable errors, parameters and errors both being derived from the randomly chosen sub-sets.

	r_2	Table 1 b_2	t_1	$\log_{10} b_2^*$
Burling	0 ± 0.02	0 ± 0.01	-5.69 ± 0.04	-3.10 ± 0.02
Present				
author	0.41 ± 0.14	-0.14 ± 0.05	-4.66 ± 0.12	-2.78 ± 0.22
		* m.sec. units.		

For the limited range of frequency in Burling's data r_2 and s_2 may be taken equal to zero with a high degree of certainty. For the larger frequency-range of my data, r_2 and s_2 may also be taken to be about equal to zero. In fact, if in the least-squares analysis of my data $r_2 = s_2 = 0$, the best values of the other two parameters are essentially unchanged from the values given in Table 1. It may be concluded then that the saturation effect noted by Burling and by Phillips does indeed exist and that it extends over a frequency-range that is more than a decade wide.

The two values of $\log_{10} b_2$ given in Table 1 differ by but little more than the sum of the probable errors. The exponents t_2 from the two sets of data do not agree within their combined probable errors. The value -5 or -2.33 for this exponent is to be expected for pure gravity waves or pure capillary waves, respectively, if the wave growth is affected only by the acceleration of gravity or by the capillary constant. That t_2 for my experiments is smaller in absolute value than for Burling's experiments may reflect the fact that some of the waves I measured are in the capillary-gravity wave regime. It should also be pointed out that the air boundary layers, for the same wind speed and fetch, were probably rather different in Burling's experiments and in mine.

Small gravity waves may well form a naturally occurring dynamical model of the larger wind waves on the ocean. If a dynamical similarity does exist, then it would be expected that ocean waves will show a saturation effect similar to that of the smaller waves and that wind waves of the two scales will be alike in many other respects. Model work on small waves on lakes and reservoirs would then provide, with but a small effort, data on wind wave generation that are significant for the waves both on lakes and on the sea. The critical question is: How complete is the supposed dynamical similarity between the generation by the wind of large and small gravity waves?

The CSL measurements were made by E. A. Huber and C. G. Whittenbury. Calculations were made on *Illic*, the digital computer of the University of

Illinois. G. Berg and C. W. Mendel wrote most of the *Illiac* programmes used in the data reduction. This work was supported by a Tri-Services Contract of the Department of Defense.

Standard Unit of Pressure in Vacuum Physics

DR. N. A. FLORESCU¹ proposes to use in vacuum physics a unit of pressure = 10^3 dynes cm.⁻², which he suggests should be called a 'vac'. A unit of this magnitude, however, has already been designated and used under the name 'millibar', and is equal to 100 newtons m.⁻². It therefore seems to me useless to invent a new name, particularly at a time when attempts are being made to limit the introduction of special names for units derived from systems in current use.

CH. VOLET

Bureau International des Poids et Mesures,
Pavillon de Breteuil,
Sèvres, Seine-et-Oise.

¹ *Nature*, 188, 803 (1960).

MANY readers of Dr. Florescu's communication in *Nature* of October 22, p. 303, on the standard unit of pressure in vacuum physics will see in it a powerful plea for the extended use of the absolute unit of pressure, the bar equal to 10^6 dynes/cm.². They will of course recognize that the proposed 'vac' is none other than the existing millibar (see, for example, British Standard 2520 (1954). Barometer Conventions and Tables). Now that the internationally adopted prefixes to abbreviations for the names of the metric units are coming increasingly into use (see for example B.S. 1991, Part 1 (1954), Symbols, Signs and Abbreviations, p. 32) there should be no difficulty in applying them to the bar and thus realizing the objective which Dr. Florescu has in mind. There is no need to introduce a new unit. For example, we have:

$$\begin{aligned} 1 \text{ vac} &= 10^{-3} \text{ bar} = 1 \text{ millibar (mb)} \\ 10^{-3} \text{ vac} &= 10^{-6} \text{ bar} = 1 \text{ microbar (}\mu\text{b)} \\ 10^{-6} \text{ vac} &= 10^{-9} \text{ bar} = 1 \text{ nanobar (nb or } \mu\mu\text{b)} \\ 10^{-9} \text{ vac} &= 10^{-12} \text{ bar} = 1 \text{ picobar (pb or } \mu\mu\mu\text{b)} \end{aligned}$$

(In each instance the abbreviation 'b' for bar can, according to a 1948 decision of the General Conference of Weights and Measures, be replaced by the complete word 'bar'.)

Regarding Dr. Florescu's plea that the millibar (or 'vac') should be recognized as granting a special significance to the value 980.7455 cm./sec.² for gravity, this should be approached with considerable reserve, bearing in mind the confusion which existed for many years between various other values associated with the term standard gravity (see B.S. 2520 (1954), p. 6). This confusion was resolved in 1950 by the International Committee of Weights and Measures when the value 980.665 cm./sec.² was re-affirmed as standard. This value is now accepted as standard for all purposes, and it is to be hoped

that no action tending towards further confusion will now be taken.

GEOFYSICS

Effects of Diffusion of Electrons near the Magnetic Equator

IN a recent interesting communication, Dr. E. R. Schermerling¹ has discussed the possible effect of vertical diffusion in the ionosphere in the presence of the geomagnetic field. He claims that the effect of diffusion is to increase the electron density below the electron peak, so that near the magnetic equator the electron density N at a given height h should be less than in slightly higher latitudes, since the magnetic field at the equator is horizontal and precludes vertical diffusion. Dr. Schermerling, however, assumes in this derivation that the rate of ion production is independent of latitude and therefore of the magnetic dip.

If we assume that the ionization is produced according to the Chapman law, this is certainly not the case, the rate of ionization increasing as the magnetic equator is approached. The two effects therefore tend to cancel each other out, and according to our calculation it seems that the increase in ionization at lower geomagnetic latitudes exceeds any decrease due to the effects of diffusion described by Dr. Schermerling. This is illustrated in Fig. 1, which shows the variation of electron density with geomagnetic latitude about an hour after midday at heights of $\frac{1}{2}$, 1 and $1\frac{1}{2}$ scale heights above the level of maximum ion production. The graph of maximum electron density (N_m) follows very closely the highest curve in Fig. 1, and we must conclude that the F^2 model under discussion, based on a hypothesis of

Fig. 1

vertical diffusion, does not account for the Appleton anomaly. It will be seen from this figure that the variation of electron density at midday is rather insensitive to changes of geomagnetic latitude. It has been suggested by various writers, however, that horizontal diffusion may affect the vertical distribution of ionization, and near the magnetic equator the tendency would be for ionization to diffuse away north and south from the equator and pile up on opposite sides of it. We are at present investigating the magnitude of this effect.

Evidence of Quasi-Perpendicular Propagation of Hydromagnetic Waves caused by Nuclear Explosions over Johnston Island

In previous reports^{1,2} one of us (H. M.) has suggested that the initial phase of artificial magnetic storms due to high-altitude nuclear explosions over Johnston Island (16° 5' N.; 169° 5' W.) may be interpreted by hydromagnetic waves propagated through the high atmosphere from the explosion point. Such a suggestion has also been made by many other workers. The purpose of this communication is to exhibit evidence supporting such a suggestion. (Quite recently, Berthold *et al.*³ have also found similar effects due to *Argus*.)

Fig. 1 shows replotted recordings of the induction magnetograph around 10h. 50m. G.M.T. on August 1, and around 10h. 30m. G.M.T. on August 12, 1958, at Shimosato (33° 6' N.; 135° 9' E.) and Onagawa (38° 4' N.; 141° 5' E.) in Japan. As has been estimated by Maeda⁴, the explosion time (and altitude) is 10h. 50m. (150 km.) on August 1, and 10h. 30m. (70 km.) on August 12, respectively. On examining carefully the magnetic traces, one finds peculiar changes around the explosion time on each day. The changes seem to consist of two parts, the first and the second arrivals, and each of them starts at the time indicated by arrows, and comes to an end about 30 sec. later. An almost complete similarity between the changes on both days at each station seems to provide the evidence that these changes are the direct effect of the Johnston Island explosions. Numerical detail of the changes read from magnetograms is summarized in Table 1.

It seems likely from these results that the changes found at Japanese stations are due to hydromagnetic waves propagated in the high atmosphere across the lines of geomagnetic force from the explosion point. If so, the propagation velocity is estimated at about 540 km./sec. for the first arrival, and about 300 km./

Fig. 1. Replotted recordings at Shimosato and Onagawa, Japan, showing geomagnetic effects due to Johnston Island nuclear explosions on August 1 and 12, 1958

sec. for the second arrival, on the average. Moreover, if we assume that the initial change at Honolulu is also caused by hydromagnetic waves, the average damping distance in which the wave is attenuated by a factor e^{-1} is estimated at about 1,650 km.

As seen in Fig. 2, the propagation path is across the lines of geomagnetic force at about 90° (that is, quasi-perpendicular propagation), so that the waves seem to be a modified Alfvén mode. Theoretical treatment of the propagation of hydromagnetic waves in a partially ionized plasma has been carried out by Akasofu⁵, Dungey⁶ and Piddington^{6,7}. According to Piddington's formulae, the propagation velocity and the damping distance depend closely on altitude in the ionospheric region. The damping distance of about 1,650 km. estimated here corresponds to an altitude of about 300 km. On the other hand, the propagation velocity at this altitude is about 10 km./sec. This value is much smaller than that deduced here. Such a disagreement results from a very simple assumption that the hydromagnetic waves are propagated along a path of constant height in the ionosphere. The actual conditions of propagation, however, seem to be much more complicated.

Thus, although it seems, at present, to be difficult to find any precise interpretation of the phenomena, the following preliminary picture may be drawn. Simultaneously with high-altitude nuclear explosions, very strong shocks are caused and propagated with high velocity. These shocks are attenuated after travelling some distances, and degenerate into hydromagnetic waves (of the modified Alfvén mode

Table 1. NUMERICAL DETAIL OF GEOMAGNETIC CHANGES AT SHIMOSATO

Fig. 2. Distance and direction from Johnston Island to observed stations, where dotted lines indicate the geomagnetic meridian

in the present case). The hydromagnetic waves will be propagated through the upper ionospheric region in the following manner: a highly ionized plasma produced by explosions pushes the geomagnetic field away, as it expands, so that a magnetic barrier may be formed in a height where the magnetic pressure of the compressed geomagnetic field equals the kinetic pressure of the plasma. Because of such a barrier, the waves may tend to be propagated horizontally; and its height seems to be lower (probably around 900 km.) than that suggested by Bomke *et al.*⁵, because both the height and the latitude of Johnston Island explosions are lower than those of *Argus*. The first and the second arrivals found here would not be due to the difference of propagation mode, but due to the difference of propagation path. If several induction-type magnetographs of high sensitivity had been used, the effects of the explosions would also be detected at more distant stations than Japanese ones.

RADIATION CHEMISTRY

Radiation-induced Carboxylation of Organic Compounds: Formation and Reactions of the Carboxyl Radical Ion

We have recently reported¹ some results on the reduction of carbon dioxide and bicarbonate in aqueous solution by cobalt-60 γ -rays and X-rays, leading to the formation of formic acid, aldehydes and small quantities of oxalic acid.

It has been found also that under these conditions the yields of molecular hydrogen were low when carbon dioxide or bicarbonate was present in the solution. From work on these reactions under different pH conditions, one is led to the conclusion that the negatively charged polarons $(\text{H}_2\text{O})^-$, formed

by the action of the radiation on water², which can react, for example, with protons according to: $(\text{H}_2\text{O})^- + \text{H}^+ \rightarrow \text{H} + \text{H}_2\text{O}$, can, in the presence of carbon dioxide or bicarbonate, react as follows³:

The existence of the CO_2^- radical ion in aqueous systems has recently been postulated also from polarographic evidence⁴.

Some of the reduction products observed in the radiolysis of solutions of carbon dioxide or bicarbonate are the result of further reactions of the CO_2^- primarily formed (or the corresponding COOH radical with which it will be in equilibrium according to: $\text{CO}_2^- + \text{H}^+ \rightleftharpoons \text{CO}_2\text{H}$); for example, dimerization of these radicals can lead to oxalic acid.

Furthermore, direct proof of the presence of CO_2^- has been obtained from experiments in which oxygen-free aqueous solutions containing suitable organic solutes (for example, alcohols, acids, aliphatic hydrocarbons, etc.) are irradiated in the presence of carbon dioxide or bicarbonate. Under these conditions, it has been clearly demonstrated that the reduced carbon dioxide can be built into the organic molecules with the formation of the corresponding carboxylic acids.

For example, irradiation of aqueous solutions of ethanol ($10^{-3} M$) in the presence of carbon dioxide (0.5 atm.) or sodium bicarbonate ($10^{-3} M$) with cobalt-60 γ -rays (dose-rate 1.8×10^{17} eV. ml.⁻¹ min.⁻¹) gave lactic acid; the yields obtained were dependent upon pH, varying between $G \sim 1$ (molecules/100 eV.) at the lower pH to $G \sim 2$ at the higher pH. The lactic acid was identified by paper chromatography. Similar experiments were also carried out with carbon dioxide or bicarbonate labelled with carbon-14; in the latter case identification and analysis were carried out by isotope dilution technique.

Under similar conditions, irradiation of aqueous methanol gave glycolic acid, and irradiation of dilute acetic acid solutions gave malonic acid. When a solution of a 1:1 mixture of methane and carbon dioxide (total pressure 1 atm.) was irradiated with γ -rays, acetic acid was found to be one of the radiation products. Irradiation of $10^{-3} M$ formic acid in the presence of carbon dioxide labelled with carbon-14 ($2 \times 10^{-3} M$) at pH 3.5 gave oxalic acid with a yield of $G \sim 1.2$, calculated as $^{14}\text{COOH.COOH}$ (unpublished results of N. Getoff and M. Simic).

All these experiments were carried out in deoxygenated solutions; this is of importance, because otherwise the negative polarons may be scavenged to a greater or lesser extent by molecular oxygen according to: $(\text{H}_2\text{O})^- + \text{O}_2 \rightarrow \text{O}_2^- + \text{H}_2\text{O}$, as shown previously⁵.

In general, the carboxylation process depends on the formation of a free radical from the organic solute by the action of the OH or $(\text{H}_2\text{O})^+$ formed by the ionizing radiation acting on the water, and association of the organic free radical with the CO_2^- radical ion formed according to reactions (1) or (2).

In the formation of lactic acid from ethanol, one has the following reactions:

Similarly, glycolic acid is formed via the radical CH_2OH produced by dehydrogenation of methanol.

The production of acetic acid from methane and carbon dioxide would involve a CH_3 radical as follows⁴:

Formation of malonic acid from acetic acid is according to the following reactions:

It has been shown also that irradiation of more complex polymer molecules, such as histones and nucleoproteins, in aqueous systems, in the presence of carbon dioxide, leads to the introduction of carboxyl groups into the molecules; this has been demonstrated using carbon dioxide or bicarbonate labelled with carbon-14 (Appleby, Emmerson, Scholes and Weiss, unpublished results).

Carboxylations with CO_2 in the gaseous state or in mixtures with solid carbon dioxide under the action of 2-MeV. electrons have been reported recently; in these cases the carboxyl compounds appear to be relatively minor reaction products as they are only formed with yields of $G = 0.01 - 0.1$ (ref. 5).

It is clear that in this way it is possible to produce labelled carboxylic compounds and, in particular, to produce some carboxylic acids labelled with carbon-14 which may be difficult to obtain in any other way.

Another application of this method of radiation-induced carboxylation would be its use in the identification and characterization of free radicals produced by radiation, as in this way the radicals could be converted into carboxylic acids which may then be identified as such, for example, by an isotope dilution technique, if carbon dioxide or bicarbonate labelled with carbon-14 is used for the carboxylation process.

One of us (M. S.) wishes to thank the British Council for the award of a fellowship. We also thank the Rockefeller Foundation and the North of England Council of the British Empire Cancer Campaign for financial support.

CHEMISTRY

Heats of Chemisorption of Simple Diatomic Molecules on Metals

THERE have been suggestions recently that the heats of formation of compounds are related to the catalytic activity of metals and heats of chemisorption¹⁻³. Fahrenfort, van Reijen and Sachtler have shown that for the decomposition of formic acid on metals there is a definite correlation between the activity of the metal and the heat of formation of the

Table 1. HEATS OF FORMATION ARE TAKEN FROM "SELECTED VALUES OF CHEMICAL THERMODYNAMIC PROPERTIES" BY ROSSINI

Compound	$-\Delta H_f^\circ(298.16^\circ \text{K.})$ kcal. mole ⁻¹	$-\Delta H$ (calorimetric) kcal. mole ⁻¹	Ref.

metal formate. A relationship between heats of oxygen chemisorption and heats of oxide formation is suggested by the recent results of Brennan, Hayward and Trapnell.

If, as a first approximation, the assumption is made that during chemisorption of diatomic molecules a two-dimensional surface compound is formed of simple stoichiometry, it would be anticipated that a correlation should exist between the heat of formation of that compound and the heat of chemisorption. Table 1 gives values for the heats of chemisorption (ΔH) of simple diatomic gases on metals determined calorimetrically and the corresponding heat of formation (ΔH_f°) of the stoichiometrically simplest compound. For example, in the oxidation of cobalt the heat of chemisorption is compared with the heat of formation of CoO and not Co₃O₄. An interesting example is the oxidation of aluminium where the heat of formation of AlO₂⁻ is used and not that of Al₂O₃. There does not appear to be any reason *per se* why the chemisorbed oxide layer on aluminium should not, in fact, have the composition AlO₂⁻. In Fig. 1 are plotted the heats of chemisorption (experimental accuracy ± 5 kcal. mole⁻¹) and the corresponding heats of formation of the stoichiometrically simplest compound.

Since values for the heats of chemisorption of gases are somewhat limited the correlation shown in Fig. 1 allows estimates to be made of such heats if the

Fig. 1. Correlation between the heats of chemisorption of simple diatomic gases on metals and the heat of formation of the corresponding simple stoichiometric compounds

corresponding heat of formation is known. Recent work (Kemball, C., Wyn Roberts, M., and Saleh, J. M., unpublished results) on the sulphiding of metals has suggested that the binding energy of sulphur to nickel at -80°C . is somewhat greater than the corresponding heat of hydrogen chemisorption ($\sim 35\text{ kcal./mole}^{-1}$). If the chemisorbed layer simulates nickel sulphide we would expect, on the above hypothesis, a value of about $50\text{ kcal./mole}^{-1}$ for the heat of sulphur chemisorption since the heat of formation of nickel sulphide is $-17.5\text{ kcal./mole}^{-1}$.

Heat of Adsorption of Hydrogen on Tungsten at Elevated Temperatures

RECENT work^{1,2} has shown that when certain hydrides are adsorbed on tungsten filaments at low pressures, and temperatures around $1,750^{\circ}\text{K}$., part is apparently desorbed as a negative ion, and a residual hydrogen atom is left bound to the tungsten surface. At the low surface coverages prevailing under the conditions of experiment, the migration of these residual hydrogen atoms to adjacent sites is relatively slow, so that the process of desorption is energetically isolated from that giving rise to negative ions. The approximate strength of the tungsten-hydrogen bond formed in this process has been put at 73.5 kcal./mole (refs. 3 and 4) based on measurements at room temperature, and this value was used in deducing the mechanism outlined above, but as an order of magnitude only. Several results have now been obtained, and the argument may be inverted, to use these results in conjunction with established electron affinities and heats of atomization, to deduce the strength of the W—H bond at these elevated temperatures. Briefly, the apparent electron affinity, E' , is related to the true electron affinity, E , the heat of atomization of the substrate, D , and the tungsten-hydrogen bond energy Q_r by the relation:

$$E' = E - D + Q_r$$

The values of E and D have been adjusted to a temperature of $1,750^{\circ}\text{K}$., the original data being taken from compilations^{5,6} except for the electron affinity of oxygen, taken from Branscomb and Smith⁷. The mean value of Q_r is $73 \pm 1\text{ kcal./mole}$, which is practically identical with the value at lower temperatures. If there was a loss of three translational degrees of freedom of the hydrogen atom in forming the W—H bond, the bond-energy would be expected

to rise by 5 kcal./mole at the higher limit of temperature, which is well outside the limits of experimental error, and the fact that the value is the same as, or slightly lower than, the room-temperature value suggests that there is a considerable degree of vibrational freedom in the adsorbed film. Two fully excited bending modes would lower the bond-energy to 72.0 kcal./mole from a value of 73.5 at room temperature, which is so close to the values obtained from the more reliable experiments with the halogen acids as to indicate that this is the true value at high temperatures. The differential heat of adsorption of molecular hydrogen on tungsten at limiting low surface coverage may readily be calculated to be 40 kcal./mole at $1,750^{\circ}\text{K}$., compared with 45 kcal./mole at room temperature.

Identification of Organic Compounds by Gas Chromatography

THE identification of unknown compounds separated by gas chromatography is often effected by comparison of their retention values with those of known compounds together with infra-red spectrophotometry or mass spectrometry. For this purpose graphs are prepared of $\log r$ against boiling point or $\log r$ on one stationary phase against $\log r$ on another stationary phase, where r is the retention time, relative retention time or the retention volume. Both non-polar and polar stationary phases are used to indicate the nature of the unknown substance. Wehrli and Kovats¹ have shown a relation between the structure of the substance and its retention values on two such phases. Stationary phase liquids which can take part in electron donor-electron acceptor interactions have also been used by Langer *et al.*² and Janak and Hrivnac³ to separate closely similar pairs of compounds. I have also found⁴ three different stationary phases to be useful in identifying components of a brown coal tar.

A method has been developed for the identification of compounds by gas chromatography alone using three stationary phases; one non-polar, one an electron donor and one an electron acceptor.

If r_1 , r_2 and r_3 are the retention times (or volumes) of a substance on the three stationary phases 1, 2 and 3 under fixed conditions, we can define an 'affinity fraction' A of the substance for each phase. For phase 1 we have $A_1 = r_1/(r_1 + r_2 + r_3)$. This enables the data for a particular substance to be plotted as a point on a triangular graph.

The retention value r_b of a compound a on stationary phase b under a fixed set of conditions is proportional to $RT/(\gamma_a^b p_a^b)$, where γ_a^b is the activity coefficient of a at infinite dilution in b and p_a^b is the vapour pressure of a at column temperature. For ideal solution behaviour r_b is governed by p_a^b . In non-ideal solution the value of γ_a^b is governed by the balance of interaction energies E between like

Table 1

Substrate	E'	E	D	Q_r
Hydrochloric acid	61	93	104	72
Hydrobromic acid	70	86	88	72
Water	-32	40	221	2×74

Fig. 1

and unlike molecules. For the simple case of a regular solution $\gamma_a^* = \exp(w/RT)$, where w is proportional to $(E_{aa} + E_{bb} - 2E_{ab})$. Thus a strong specific interaction of donor-acceptor type between the substance and the stationary phase liquid leads to a large retention value.

Retention times were measured for a number of substances at 125° C. on three 2.5-m. columns each containing 1.5 gm. of stationary phase on 9 gm. of 'Celite 545' using a nitrogen inlet pressure 1,000 mm. mercury above the outlet pressure, which was atmospheric. The A values for the substances were calculated and are shown in Fig. 1, where A_1 refers to 'Apiezon L', A_2 to 'Reoplex 400', polyester (electron donor) and A_3 to 1,3,5-trinitrobenzene (electron acceptor). Substances with low polarity have high values of A_1 ; $1/A_1$ is approximately proportional to the dielectric constant of the substances chromatographed. Compounds with a protonic function (electron acceptors) have high values of A_2 , and substances which can act as electron donors have high values of A_3 . Thus each compound has a position on the graph governed by its electron acceptor-donor properties and the group of points

for each homologous series of compounds lie on a line pointing towards the 'Apiezon L' apex.

This method, together with the use of the three individual retention values, is being applied to the identification of the components of coal tar and should prove useful in the identification of the degradation products of other substances of low volatility. The method should prove useful in studying the electron donor and acceptor properties of volatile substances and of non-volatile liquids used as stationary phases. Further applications may be possible in interpreting and predicting the course of organic substitution reactions which are governed by the electron distribution in the reacting molecules.

Some Experiments on Rice's Blue Material: Colours on Jupiter

Clarke and McTurk¹ have recently claimed that Rice's blue material can be prepared by passing ammonia through an electrical discharge tube and partially freezing out the decomposition products on a cold finger, placed about 2 cm. from the nearest electrode.

Since this observation conflicts with the results of extensive experiments carried out earlier by Rice and Freamo², we repeated the work of Clarke and McTurk; but, in spite of intensive effort, we have been unable to produce the blue material from ammonia. We realize, of course, that the negative results reported in this communication, as well as those of Rice and Freamo, do not prove conclusively that the blue material cannot be formed from ammonia using the above technique, since the conditions may be very critical and difficult to duplicate.

In our experiments we used tank anhydrous ammonia as supplied by the Matheson Co. The ammonia was passed, at pressures varying from 0.1 to 2.0 mm. of mercury, through an a.c. discharge powered by a transformer rated at 10,000 V. and 50 m.amp. current. The power supply to the discharge tube could be diminished at will by means of a Variac placed between the primary coil of the transformer and the power source. The products from the discharge were partially frozen out on a cold finger at 77° K., which was about 2 cm. from the nearest electrode. In each series of experiments a discharge tube of different dimensions was used, the length being varied from 9 in. to 8 ft., the diameter from 1 to 3 cm. The electrodes were of iron except for a few experiments in which aluminium electrodes were used.

If hydrazoic acid were substituted for ammonia, we always obtained the characteristic blue deposit on the cold finger except when the current density was sufficiently high to decompose all the hydrazoic acid. Whenever this occurred, we could always obtain the blue colour by diminishing the voltage supplied to the primary of the transformer.

Since Clarke and McTurk report: "In one experiment the uncondensed gas was sampled and found by mass spectrograph to be largely hydrogen, with small amounts of nitrogen and oxygen in the ratio of 4:1", we assumed that air leaked into their apparatus, and that possibly nitrogen trioxide was formed; this is blue when condensed on a surface cooled with liquid nitrogen. We, therefore, did a whole series of runs in which mixtures of ammonia and air were passed through the discharge tube, but we never succeeded in obtaining a blue deposit. We did a few experiments in which we mixed nitric oxide with small quantities (about 10 per cent) of air and passed the gas mixture, without any discharge, on to the cold finger. Under these conditions we did obtain a blue deposit of nitrogen trioxide which in colour and in its behaviour on warming could have been mistaken for the blue material. However, we never succeeded in finding any conditions under which nitrogen trioxide could be frozen out from mixtures of ammonia and air or nitrogen and water vapour on passage through a discharge tube.

These experiments on nitrogen oxides are of some importance in connexion with colours on Jupiter³. Recently, Kiess *et al.*⁴ have shown that oxides of nitrogen are present on the atmosphere of Mars,

and the suggestion has been made that the colours on Jupiter are due to frozen-out oxides of nitrogen, even though Jupiter is a 'reduced' planet. It is conceivable that non-equilibrium conditions exist on Jupiter and that the violent electrical storms might possibly result in the freezing-out of oxides of nitrogen formed by reaction of nitrogen atoms and oxygen atoms. The oxygen atoms would presumably result from the dissociation of water which may be whirled about in the turbulent Jovian atmosphere as tiny ice particles.

BIOCHEMISTRY

Metabolism of β -Sitosterol and Other Lipids in the Presence of Acetate-2-¹⁴C by Blowfly Larvæ

It has been shown recently that the ability to convert C₂₇₋₂₈ sterols to cholesterol is likely to be a general attribute of phytophagous insect larvæ¹. In the case of β -sitosterol, this conversion could occur either by removal of the side-chain and *de novo* synthesis of the cholesterol side-chain or by elimination of the supernumerary carbon atoms to yield the *iso-octyl* side-chain. Enzymes capable of cleaving the side-chain of sterols are known to occur in mammals² and certain bacteria³.

Although blowfly larvæ are not as efficient in converting sitosterol into cholesterol as obligatory plant feeders, they were selected for the present work because they grow sufficiently rapidly to avoid randomization of the isotopic carbon; they also grow readily on a synthetic diet and under aseptic conditions.

Larvæ of *Calliphora erythrocephala* were reared at 29° aseptically⁴ at a density of seven animals per 10 gm. of a synthetic diet⁵ in which cholesterol was replaced by purified β -sitosterol (m.p. 140°; [α]_D²⁰ -36). Sodium acetate-2-¹⁴C was diluted with carrier acetate and 2.5 mgm. added to 40 gm. of this diet, amounting to a concentration of 6.25 mgm. per cent; the specific activity of the sodium acetate was 12 μ c./mgm. The diet was continuously aerated with air free from carbon dioxide and kept in darkness during the 6 days of larval growth. At the end of this period the 27 surviving animals had attained their maximum body-weight (mean larval weight, 92 mgm.) and were used for analyses; the radioactivity of the samples was measured with a thin end-window tube with an accuracy of $\pm$ 5 per cent and corrected for self-absorption in the usual manner.

The desiccated larvæ (578 mgm.) contained 19.7 per cent of ethylether-chloroform-acetone-extractable lipids, of which 83.6 per cent consisted of fatty acids and 11.5 per cent of unsaponifiable matter; of the latter, 10.7 per cent were recovered as sterols, precipitable by digitonin. Table 1 shows the radioactivity of the various fractions. The most

Fig. 1. Reversed-phase chromatogram of *Calliphora* sterols on Whatman paper No. 8, impregnated with 5 per cent paraffin, B.P.; ascending run for 17 hr. in ethylene glycol-mono-ethyl ether - abs. methanol - *n*-propanol - water (82.5:5.35:15:17.5). Chromatogram sprayed with antimony trichloride solution in chloroform and warmed for 2 min. on hot plate

striking feature is the negligible activity of the sterols. Moreover, the latter, when chromatographed on paraffin-impregnated filter paper⁴ to separate the newly formed cholesterol from β -sitosterol (Fig. 1), did not show any radioactivity on X-ray films ('Kodirex'), after an exposure of 6 weeks. These findings not only confirm that *Calliphora* larvae, like *Dermestes vulpinus*⁷, are unable to synthesize sterols from ^{14}C -acetate, but indicate also that the cholesterol side-chain is not formed by re-synthesis from acetate, but rather by de-ethylation of the β -sitosterol side-chain at position C_{24} . An analogous de-methylation of ergosterol has been shown to occur in nymphs of *Blattella germanica*⁸. On the other hand, it has been claimed that adult *Peryplaneta americana* incorporate ^{14}C -labelled acetate into their tissue sterols⁹.

The results in Table 1 suggest that acetate is being utilized at least as efficiently for the biosynthesis of

fatty acids as for the biosynthesis of the unsaponifiable matter, other than sterols; about 2.3 parts of acetate were incorporated into 1,000 parts of fatty acids. The remainder of these must be derived from other carbon sources, which in the absence of glucose in the diet⁵ are obviously amino-acids. A similar observation has been made with housefly larvae reared on a carbohydrate-free medium⁴. Adults of *Prodenia eridania* have been found to synthesize long-chain fatty acids also from acetate, which was better utilized than glucose¹⁰.

Table 1. DISTRIBUTION OF RADIOACTIVITY IN BLOWFLY LARVAE GIVEN ACETATE- $2\text{-}^{14}\text{C}$ IN THE DIET

Material	Radioactivity		
	Specific activity ($\mu\text{mc./mgm.}$)	Total ($\text{m}\mu\text{c.}$)	Percentage of dietary acetate- $2\text{-}^{14}\text{C}$
Total lipids	25.3	2,884	9.6
Unsaponifiable matter	22.4	293	1.0
Digitonin-precipitable sterols	0.3	0.4	0.001
Digitonin-non-precipitable	21.1	181	0.6
Fatty acids	27.8	2,649	8.8
Lipid-free residue	1.0	464	1.5
Total carbon dioxide expired by larvae	—	314	1.0

Significant amounts of carbon-14 were incorporated into the unsaponifiable lipids, other than sterols; this uptake amounted to an incorporation of 1.7 parts acetate in 1,000 parts of the digitonin-non-precipitable, unsaponifiable matter. This fraction could be separated by reversed-phase paper-chromatography⁴ into 4 radioactive spots, A—D, with R_F 0.65, 0.74, 0.89 and 0.97, respectively; the spots B and C were the most radioactive ones (Fig. 2). Preliminary infra-red analyses on this fraction, kindly performed by Dr. N. Sheppard, showed a spectrum of a compound with an aliphatic hydrocarbon chain, particularly of a long-chain carboxylic acid (shoulder towards $2,650\text{ cm.}^{-1}$ due to stretching of $-\text{OH}$, peak at $1,707\text{ cm.}^{-1}$ of $-\text{C}=\text{O}$ from $-\text{COOH}$, shoulder at $1,415\text{ cm.}^{-1}$ for $-\text{CH}_2-[\text{C}=\text{O}]$, peak at $1,287\text{ cm.}^{-1}$ with shoulders due to $-\text{C}-\text{OH}$ of $-\text{COOH}$, and peak at 933 cm.^{-1} due to $-\text{OH}$ of $-\text{COOH}$, angle-bending

Fig. 2. Autoradiogram and counts of the reversed-phase chromatogram of the unsaponifiable, digitonin-non-precipitable matter (790 $\mu\text{gm.}$) of *Calliphora* larvae. Whatman paper No. 3, impregnated with 5 per cent paraffin, B.P.; ascending run for 17 hr. in abs. methanol - *n*-propanol - water (80:15:5)

vibration). There was no indication of the presence of an aldehydic or keto group. Branched $-\text{CH}_3$, if any, were few (a small peak at $1,377\text{ cm}^{-1}$). The presence of double bonds could not be ruled out as the $-\text{C}=\text{C}-$ frequency could have been hidden by the large $-\text{CO}$ peak centred at $1,707\text{ cm}^{-1}$. Peaks at $717, 1,465, 2,850$ and $2,930\text{ cm}^{-1}$ indicated a fair amount of CH_2 groups in an alkyl chain of considerable length. The nuclear resonance spectrum was consistent with that obtained by infra-red light; four peaks were observed (a weak one in the position of $-\text{CH}=\text{C}$, stronger bands due to $-\text{CH}_2-[\text{C}=\text{O}]$, alkyl chain $-\text{CH}_2$, and a few terminal $-\text{CH}_3$). The ultra-violet spectrum showed ill-defined shoulders at 220 and $250\text{ m}\mu$.

The larvae still contained significant amounts of radioactivity after removal of their lipids; one can therefore assume that acetate was used also for the synthesis of non-lipidic constituents of the body. The ability of *Calliphora* larvae to incorporate ammonia into alanine, glutamic and aspartic acids⁶ should be recalled in this respect.

The total barium carbonate derived from the expired carbon dioxide was 2.48 gm. for 27 surviving larvae during 6 days. The expired carbon dioxide amounted thus to $20.5\text{ mgm./6 days/larva}$ or to an average of $3.2\text{ }\mu\text{moles (72 }\mu\text{l.) carbon dioxide/hr./larva}$, out of which, according to the carbon-14 count, only 1 part in 2,000 could have been derived from acetate- $2\text{-}^{14}\text{C}$, the rest from other carbon sources.

We wish to thank Dr. N. Sheppard for the analyses and interpretation of the infra-red and nuclear resonance spectra. One of us (Z. H. L.) wishes to acknowledge a Sir Simon Marks Fellowship awarded by the Research Council of Israel.

Immunoelectrophoresis of Human Sera with Antiserum to Raben Growth Hormone

DURING investigations in progress using the immunological method for the assay of growth hormone in human serum^{1,2}, attempts have been made to show a reaction between human sera and rabbit antiserum to the Raben preparation of human growth hormone, made in Cambridge, in Ouchterlony plates and on electrophoretic strips.

On micro-immunoelectrophoresis in agar gel³, human serum gave a precipitin line with the antiserum in a position corresponding with the albumen band. This line was found when normal sera and when various sera including those from acromegalic and myxoedemic patients were tested against antiserum prepared from each of four rabbits. Serum from normal non-immunized rabbits and from rabbits injected with the adjuvant mixture alone did not give this line.

Each of the four rabbits was immunized by a primary injection of 1 mgm. of Raben human growth hormone in water-in-oil emulsion ('Arlacel A'/'Bayol F') containing $200\text{ }\mu\text{gm.}$ of purified glycolipid of *Mycobacterium tuberculosis* strain 'Test', followed by a secondary injection at multiple sites six weeks later of a total of 0.5 mgm. of Raben growth hormone adsorbed to aluminium phosphate. The sera from animals bled 10 days later yielded haemagglutination titres⁴ of $1/800\text{--}1/9,600$.

The line described above does not appear after absorption of the antiserum with Raben growth hormone, and evidently its formation is dependent on antibody formed against a component of Raben growth hormone. No reaction has been found against other components of human serum, such as were described by Hirschfeld *et al.*⁴ using antisera to a Li and Papkoff⁵ preparation of human growth hormone.

By the Ouchterlony technique, Li *et al.*⁶ described reactions of identity between human growth hormone and pituitary mash put up against rabbit antiserum to growth hormone. On immunoelectrophoresis of Raben growth hormone mixed with human serum the present investigation has shown the formation of single precipitin lines against both the albumen and the Raben growth hormone bands. Identical lines were obtained on immunoelectrophoresis of human pituitary mashed in saline. Addition of human serum to the pituitary mash before immunoelectrophoresis failed to produce more than one line against the albumen band, so that the appearance of this line in the pituitary mash could be due to the contained serum. These lines clearly crossed in each of the above experiments (Fig. 1), indicating non-identity of the antigen antibody systems. In Ouchterlony plates the precipitin lines against human serum and Raben growth hormone failed to show a reaction of identity.

It is of interest that Gemzell⁷ has reported biological growth hormone activity in a precipitate of human serum proteins composed mainly of albumen. Human serum albumen (kindly provided by the Lister Institute) was found to react with the four rabbit

Fig. 1. Immunoelectrophoresis of human pituitary mash in saline, with the rabbit antiserum to Raben human growth hormone, showing precipitin lines against the growth hormone (A) and albumen (B) bands, which clearly cross. Half an identical electrophoretic run is shown stained with nigrosin to demonstrate the protein bands.

antisera. After absorption of the antisera with the albumen, precipitin lines still appeared against the Raben growth hormone but not against the albumen band in serum. Following pituitary destruction in two cases in which the immunological assay for growth hormone fell considerably, the precipitin line against the albumen spot cannot be demonstrated.

These results could depend on the contamination of Raben human growth hormone with human serum albumen; but these investigations have not excluded the possibility that a component of human growth hormone is carried *in vivo* on the serum albumen or that the second protein present in the Raben growth hormone is also dependent on the pituitary.

The presence of an immunologically active contaminant in the growth hormone used as antigen might invalidate an immunological method of assaying growth hormone in human serum, unless the non-specific antibody could be absorbed out, as seems possible from the experiment described above. If the reactive material in serum is considered to be growth hormone then it is so immunologically distinct from that prepared from the pituitary that the immunological assay using pituitary growth hormone as a standard may not give absolute or even comparative values for levels of growth hormone in serum.

Various investigations are in progress for the elucidation of these phenomena.

I thank Prof. C. Wilson for his encouragement and advice and Dr. R. G. White and Dr. A. Stuart Mason for much constructive guidance and criticism. The Raben preparation of human growth hormone was kindly made available by the Medical Research Council Committee on Human Growth Hormone.

Synthesis of N-Phosphoryl-D- and L-Lombricine

THE isolation of the phosphagen of the earthworm in an impure form was reported by Thoai *et al.*¹ in 1953. The compound was Sakaguchi-negative² and on mild acid hydrolysis yielded equimolar proportions of phosphoric acid and lombricine (2-amino-2-carboxyethyl 2-guanidinoethyl hydrogen phosphate). It was concluded that the compound had the following structure:

We have already reported³ that the reaction of N-phosphoryl-O-methylurea⁴ with 2-amino-2-carboxy-

ethyl 2-aminoethyl hydrogen phosphate (serine ethanolamine phosphodiester) leads to the formation of a compound with properties similar to those of the substance isolated from earthworms by Thoai *et al.*¹. The product resulting from the use of L-serine ethanolamine phosphodiester in this reaction has now been isolated by fractionation of the reaction mixture on 'Dowex-50 (H⁺)' ion-exchange resin. It was obtained in 70 per cent yield as an amorphous ammonium salt, which was converted to a microcrystalline powder by recrystallization from aqueous methanol. Titration and elementary analytical data are in agreement with this material, being a mixture of the mono- and di-ammonium salts of L-2-amino-2-carboxyethyl 2-N-phosphorylguanidinoethyl hydrogen phosphate. Analysis: calculated for a mixture of 1 part of the monoammonium salt (C₈H₁₅O₇N₃P₂·NH₄·½CH₃OH) and 4 parts of the diammonium salt (C₈H₁₄O₇N₄P₂·2NH₄·½CH₃OH): C, 19.67; H, 5.94; N, 20.47; P, 15.61 per cent; found: C, 19.55; H, 5.96; N, 20.10; P, 15.54 per cent. *pK_a* values (potentiometric): c. 2, 4.6 and c. 8.8; as the substance was in the form of its ammonium salt the *pK_a* of the guanidino group could not be determined. It had main infra-red absorption peaks at 777, 969, 1,056, 1,084, 1,220, 1,309, 1,349, 1,413, 1,458, 1,628, 3,020 and 3,180 cm.⁻¹.

The product did not react with the Sakaguchi⁵ or α-naphthol/diacetyl⁶ reagent, but did react with ninhydrin and the molybdate reagent⁷ for phosphate. On paper chromatography in a number of solvent systems it was homogeneous in respect to the latter two reagents. Hydrolysis in 0.1 N hydrochloric acid for 1 min. at 100° caused complete conversion to phosphoric acid and a guanidine base behaving as lombricine on paper chromatography. The base was further characterized as lombricine by its behaviour on nitrous acid degradation⁸. Thus, guanidination with N-phosphoryl-O-methylurea⁴ occurs preferentially, as it does with O-methylurea^{9,10}, at the terminal amino group of serine ethanolamine phosphodiester.

Direct phosphorylation of D-lombricine (isolated from earthworms) with phosphoryl chloride in strongly alkaline solution gave in 13 per cent yield a product (isolated similarly as an essentially diammonium salt) which was Sakaguchi- and α-naphthol/diacetyl-negative and had an infra-red spectrum and *R_F* and *pK_a* values identical with those found for the product described above. The isolation of natural material for comparison with the synthetic compounds is in progress.

The method of synthesis of the product obtained from serine ethanolamine phosphodiester establishes that the phosphoryl residue is located on one of the two unsubstituted nitrogen atoms of the guanidino group of lombricine; because of resonance within the zwitterionic phosphorylguanidinium group⁹ these two positions are identical. That the phosphoryl residue in the product obtained by the phosphorylation of lombricine occupies a similar position is shown by the identity of the infra-red spectra of the two compounds. It may be concluded, therefore, that both products have the structure shown.

The general question of the precise location of the phosphoryl group of phosphagens derived from monoalkylguanidines, and of the identity of the natural and synthetic preparations, will be discussed at greater length in a subsequent communication. It is, however, relevant to point out here that with

the exception of the two synthetic preparations described above and the N-phosphoryl-glycoeyamine recently synthesized by Cramer and Vollmar¹⁰ via N-diphenylphosphoryl-S-methylurea, the accepted position for the phosphoryl residue in all these preparations—on one of the unsubstituted nitrogen atoms of the guanidino group of the parent base—although perhaps correct, remains unproved. Thus it appears that the only direct evidence in support of this formulation is based on the fact that phosphagens do not give a colour reaction with the α -naphthol/diacetyl reagent, and on the supposition¹¹ that N-phosphorylguanidines will show the same specificity towards this reagent as do simple alkylguanidines, of which only the mono- and *asym* di-substituted react¹². That this supposition is unwarranted follows from an observation made in the course of the present work that phosphorylguanidine itself (prepared by the method of Cramer and Vollmar⁹, or by treating N-phosphoryl-O-methylurea with aqueous ammonia) gives no colour reaction with this reagent.

With the exception noted above¹⁰, previous syntheses of phosphagens derived from mono-alkylguanidines have invariably involved the reaction of phosphoryl chloride with the guanidine base in a strongly alkaline medium. It would seem likely, by analogy with the structure of the phosphorylation product of lombricine, that the phosphoryl group of these products is, indeed, in the accepted position, that is, on one of the unsubstituted nitrogen atoms of the guanidino group of the parent base. Although these synthetic preparations have been claimed¹¹ to be identical with the natural, there seems insufficient evidence available at present to warrant any definite conclusion on this point.

These questions are now under investigation and the results, together with a complete account of the present work, will be published elsewhere, but already from the work reported here, the potential value of the synthetic method involving N-phosphoryl-O-methylurea and its derivatives in orientating the phosphoryl residue throughout this group of naturally occurring compounds is clear.

We are indebted to Dr. J. E. Fildes and staff, to Dr. E. Spinner and Mr. D. T. Light, and to Dr. D. Perrin and Mr. H. Satrape, of the Department of Medical Chemistry, for microanalyses, infra-red spectra and pK_a determinations, respectively.

Synthesis of Thiamine and Folic Acid by *Nocardia rhodnii*, the Micro-symbiont of *Rhodnius prolixus*

STRONG suggestive evidence¹ exists to support earlier proposals² that *Nocardia rhodnii*, the extra-cellular symbiont of *Rhodnius*, contributes essential food factors to its host. In recent years, however, the evidence has been conflicting, particularly where it concerns the nature of these factors. In 1954, Geigy, Halff and Kocher³ isolated a micro-organism from *Triatoma infestans* similar to *N. rhodnii* and found that whereas it synthesized thiamine and other vitamins in minimal amounts, there was a 2,500-fold hyper-production of folic acid. Bewig and Schwartz⁴, however, later claimed that this organism was not *N. rhodnii*, and was not symbiotic. They showed that pure cultures of *N. rhodnii* on an elaborate semi-synthetic medium synthesized minimal amounts of folic acid, no vitamin B₁₂, and no folinic acid. They found too that injection of vitamins into sterile *Rhodnius* failed to induce moulting. In 1956 Baines⁵, using feeding and injection techniques, came to the conclusion that *Rhodnius* is dependent on *N. rhodnii* for pyridoxine, calcium pantothenate, nicotinamide and thiamine, but that biotin and folic acid are present in adequate concentration in the host blood to meet the requirements of *Rhodnius*.

The two experiments described here attempt to throw further light on the synthesis of folic acid and thiamine by *N. rhodnii* and *Rhodnius*. Techniques involving the injection of vitamins into insect or mammalian host were avoided. In the first experiment, the vitamins were fed artificially to sterile bugs using my technique⁶, and in the second the synthesis of the two vitamins by *N. rhodnii* was determined microbiologically⁷.

Exp. 1. The effect of rabbit blood supplemented with folic acid and/or thiamine, as a diet for sterile 4th instar *Rhodnius*.

Sterile insects do not respond well to artificial feeding, and only small volumes of blood are usually ingested. This difficulty was overcome by adding the test vitamins to oxalated horse blood in such concentrations that the small amount of blood taken in would contain approximately the quantity of vitamins required for the experiment. The weight of blood ingested, and hence the amount of vitamin, was determined by rapidly weighing the bugs before

Table 1. EFFECT OF FOLIC ACID AND/OR THIAMINE ON THE MOULTING OF STERILE 4TH INSTAR *Rhodnius* FED ON SMALL AMOUNTS OF HORSE BLOOD CONTAINING THE VITAMINS, FOLLOWED BY CAPACITY MEALS ON THE RABBIT EAR

Group	Diet	No. used	Mean amount of vitamins introduced (μ gm.)	Effect
A	(Horse blood) + full feed on rabbit	8	—	No moults in 70 days
B	(Horse blood + folic acid) + full feed on rabbit	2	0.085	No moults in 70 days
C	(Horse blood + thiamine) + full feed on rabbit	2	0.18	Both moulted in 41 and 53 days
D	(Horse blood + folic acid + thiamine) + full feed on rabbit	2	0.02 folic acid 0.075 thiamine	Both moulted in 15 and 26 days
E	Full feed on rabbit (normal, infected bugs)	98	—	Mean moult period: 15.5 days

and after feeding. The amount of blood ingested represented about 25 per cent of a capacity blood meal. After weighing, the bugs were placed on the ear of a rabbit when they fed to repletion. The results show that the amount of horse blood introduced into the bugs before the rabbit feed does not affect the time of moulting of the experimental insects.

The results analysed statistically show that the delay in groups *A* and *B* compared with the control, *E*, is readily apparent. It is also significant, in the main, for group *C*; for group *D*, any delay in moulting must remain in doubt. It also seems apparent that folic acid and thiamine together have a far more significant effect than either vitamin alone.

Exp. 2. Quantitative microbiological estimations of thiamine and folic acid synthesis by *N. rhodni* in sterile horse blood.

Pure cultures of *N. rhodni* were isolated from infected bugs and kept at 30° on nutrient agar slopes. Microscopical examination did not show any accompanying organisms. Sterile horse blood was chosen as the culture medium as blood is the natural substrate of *N. rhodni* in the *Rhodnius* gut. 1 day before the commencement of the experiment, a sub-culture from the original agar slopes was transferred to a liver peptone broth and incubated at 30°. On the first day the culture from this broth was washed with, and suspended in, isotonic saline. Three drops of this pure culture in suspension were used as the inoculum, and were added to two of three tubes of 5 ml. freshly drawn, sterile horse blood. The third sample of blood was not inoculated and served as the control.

Levels of thiamine and folic acid in control and inoculated groups were determined at the beginning of the experiment and after 3 and 7 days (Table 2).

Table 2. VITAMIN SYNTHESIS BY *N. rhodni* IN HORSE BLOOD (Values expressed as $\mu\text{g}/\text{ml}$.)

Time in days after inoculation	Thiamine		Folic acid	
	Normal blood control	Inoculated blood	Normal blood control	Inoculated blood
First	36	—	28	—
Third	33	35	32	71
Seventh	41	96	29	122
	37 (mean)	—	30 (mean)	—

The results show that by the seventh day there is a 2.6-fold increase in the thiamine-level in the inoculated blood over that in pure, *Nocardia*-free blood, and a 4-fold increase of folic acid. Using Bewig and Schwartz's figure⁶ for the folic acid requirements of *N. rhodni* as 0.1 $\mu\text{g}/\text{cm}^3$, it can be seen that in the present experiments this organism produces about 920 times its own requirements of folic acid. Without knowing the thiamine requirements of the organism, it is not yet possible to determine what excess of this vitamin is produced.

It therefore seems likely that both folic acid and thiamine are synthesized by *N. rhodni* in such amounts that the excess over the organism's own requirements could be made available to its host for its satisfactory growth and development.

This work forms part of a study for the degree of Ph.D. of the University of London, and was carried out under the late Prof. P. A. Buxton, whose helpful criticisms, together with those of the present head of the Department, Prof. D. S. Bertram, I much appreciate. It was financed by the South African

Council for Scientific and Industrial Research, the support of which I wish to acknowledge.

Effect of Degeneration on the 'Albumin' Components of Human Muscle Extracts

JACOB¹ showed that a fast-moving group of proteins, which he called group III, was observed when low ionic strength extracts of rabbit striated muscle were subjected to moving boundary electrophoresis. The group consisted of a major and a minor component; the major component, unlike the minor, was soluble in distilled water and he considered that it probably corresponded to the myoalbumin described by Bate-Smith². Subsequent reports³⁻⁵ have claimed that this group increases relative to other proteins in the muscle extracts when the striated muscle of various species, including man, degenerates as a result of pathological and experimental lesions. The increase has been attributed to an increase of myoalbumin. Recently, Corsi and Buscaino⁶ have pointed out that much of the group III fraction is likely to consist of serum albumin. However, since the electrophoretic techniques used previously appear to have resolved only one albumin component, interpretation of the results is ambiguous. In view of this the following preliminary observations may be of interest.

I have recently described⁷ the use of starch-gel electrophoresis by Smithies's method⁸ for the separation of the human muscle proteins which are soluble at low ionic strength. At that time the occasional separation of the albumin fraction into two components was reported; in this context, by the albumin fraction is meant the fastest-moving fraction seen after starch-gel electrophoresis and which has albumin-like solubility characteristics. When separation occurred the slower component moved at the same speed as serum albumin. Further investigation has defined the conditions under which the albumin fraction of muscle extracts can be invariably separated into two components. Both components, like the major component of Jacob's group III, are soluble in ion-free water. Although the relative amounts of the two components vary considerably, some peroxidase activity is always associated with the faster component, but not with the slower under the conditions of the present experiments. The significance of this observation is as yet unknown, and it is included merely as indicating a

dissimilarity, other than in electrophoretic mobility, between serum albumin and the muscle protein.

The factors influencing the speed of migration of proteins on starch may be rather complex⁵; nevertheless, the relative mobilities are such as to suggest that the faster component may be myoalbumin, since Bate-Smith² showed that this had a lower isoelectric point than the corresponding serum albumin.

Fig. 1. Starch electropherogram of two muscle extracts run in parallel: A, Normal muscle; B, atrophied muscle. Buffer, 0.03 M *tris*-(hydroxymethyl) amino methane/hydrochloric acid, pH 7.7. m, Myoglobin; s, serum albumin

Fig. 1 is a photograph of a starch-gel electropherogram in which low ionic-strength extracts of a normal (A) and an atrophied human muscle (B) have been run side by side. Atrophy in this case had resulted from severe chronic denervation. Several components, for example the myoglobin band, have largely disappeared from the electropherogram of the atrophied muscle; but the bands due to the albumin components are of similar intensity in the two cases and hence these components are proportionately increased. Although the relative amounts of the two albumins are not always quite the same as in the example shown, nevertheless, when muscle degeneration is accompanied by a marked reduction in the intensity of certain characteristic bands on the starch electropherogram, no obvious reduction in the intensity of either albumin band occurs. The proportionate increase in serum albumin probably reflects a decrease in the intracellular space relative to the extra-cellular space resulting from destruction of muscle cells. On the other hand, the increase in the faster component, which may be human myoalbumin, is understandable if it represents, as Fischer³ has suggested, a breakdown product of other muscle proteins.

This work, which is continuing and will be reported in detail elsewhere, was supported by a research fellowship of the Mason (Chiswick) Medical Research Trust.

Characterization of Deoxyribonucleic Acid from *Anacystis nidulans*

THE chemical nature of deoxyribonucleic acid in blue-green algae was not known until very recently¹⁻³. This communication deals with a quantitative study of deoxyribonucleic acid from *Anacystis nidulans* and its characterization in respect to that from other sources. *Anacystis nidulans* and *Chlorella ellipsoidea*

were grown in continuous culture chambers as described earlier^{4,5}. The algal cells were treated with cold 10 per cent trichloroacetic acid, 95 per cent alcohol, alcohol/ether (3:1) and finally with ether until all the pigments except phycobilins were fully extracted. Deoxyribonucleic acid was isolated by one of the following procedures: (a) with 10 per cent sodium chloride (2 ml./10 mgm.) three times by refluxing at 80° C. for 1 hr. each time⁶; (b) with 1 N potassium hydroxide at room temperature⁷; (c) with 0.5 M perchloric acid⁸. Purification of deoxyribonucleic acid from

protein and polysaccharide was done according to the methods described earlier⁹. Chromatographic analyses were done according to Wyatt¹⁰. Purines and pyrimidines were estimated by maximum extinction technique¹¹. With different procedures of extraction it has been observed that the yield of purified deoxyribonucleic acid varies from 3.7 to 4.7 per cent of the dried cells after ether wash. The fresh weight of the cells was found to be 5 times that of the dried ether-washed cells and hence deoxyribonucleic acid constitutes 0.73-0.94 per cent of the fresh weight of the cells. Nitrogen content varies from 13.9 to 14.3 per cent and that of phosphorus from 6.8 to 8.2 per cent with different procedures of isolation. Deoxyribonucleic acid is found to have an absorption maximum at 257 mμ and minimum at 230 mμ. The infra-red spectrum of deoxyribonucleic acid from *Anacystis* does not show any remarkable deviations from those of other sources. The main peaks are at 3, 6.1, 8.1 and 9.3-9.8μ. The percentage of molar ratios of constituent bases, guanine, adenine, cytosine and thymine, in deoxyribonucleic acid of *Anacystis* was found to be 29.5, 23.3, 24.8, and 22.3 respectively. The ratios of G/C, A/T and Pu/Py were 1.19, 1.04 and 1.12 respectively. The average values only have been recorded here. The deviation of unity in base ratio in this case is very difficult to explain at present, though the presence of single-stranded deoxyribonucleic acid which has recently been isolated from bacteriophage¹² cannot be ruled out. The (A + T)/(G + C) ratio may be used as a species parameter. In the case of *Anacystis nidulans* this was found to be about 0.82.

The deoxyribonucleic acid from *Anacystis nidulans*, *Chlorella ellipsoidea* and sperm (obtained from Nutritional Biochemical Corporation, Cleveland, Ohio) was degraded with deoxyribonuclease in the following way. 48 mgm. deoxyribonucleic acid, 1.28 mgm. deoxyribonuclease in 0.003 M magnesium sulphate and 0.02 M phosphate buffer pH 7.6, total volume being 4.8 ml., was incubated at 37° C. for 24 hr. The deoxyribonuclease hydrolysate was chromatographed in isopropanol/water (7:3) with ammonia in vapour phase¹³. The incubation of

Table 1. MOLAR PROPORTIONS OF BASES IN THE FIRST BAND AFTER CHROMATOGRAPHIC SEPARATION OF DEOXYRIBONUCLEASE HYDROLYSATE AND IN THE CORE AFTER 24 HR. OF DEOXYRIBONUCLEASE TREATMENT AND DIALYSIS

	Source	G	A	C	T	G/C	A/T	Pu/Py
First band	<i>Anacystis nidulans</i>	32.5	23.5	25.5	18.5	1.27	1.27	1.27
Core, 18-20 per cent	<i>Anacystis nidulans</i>	33.5	23.2	24.5	18.7	1.37	1.24	1.31
First band	<i>Chlorella ellipsoidea</i>	33.0	22.0	23.0	22.0	1.50	1.00	1.22
Core, 18-20 per cent	<i>Chlorella ellipsoidea</i>	32.6	23.5	22.5	21.4	1.44	1.10	1.28
First band	Sperm	20.5	38.0	15.5	23.0	1.32	1.28	1.30
Core, 34-40 per cent	Sperm	20.8	39.2	17.6	22.4	1.18	1.75	1.50

First band of deoxyribonuclease hydrolysate after chromatographic separation (isopropanol-water, ammonium) was eluted in 0.1 N hydrochloric acid, hydrolysed with 12 N perchloric acid and the proportion of bases was determined spectrophotometrically. The methylcytosine in the case of sperm deoxyribonucleic acid was not detected after perchloric acid hydrolysis. Core signifies the non-dialysable fraction when digestion was carried out in dialysis tubes against 500 ml. of distilled water. 48 mgm. of deoxyribonucleic acid was used.

Table 2. ELECTROPHORETIC SEPARATION OF CHROMATOGRAPHIC BAND 3 OF THE DEOXYRIBONUCLEASE HYDROLYSATE

Spot No.	Electrophoretic mobility (cm.)	Identity	Source
1	0	pC	<i>Anacystis</i> , <i>Chlorella</i> , sperm
2	2.5-3.5	pAPC	<i>Anacystis</i> , <i>Chlorella</i> , sperm
3	4.5-5.5	pGpC	<i>Anacystis</i> , <i>Chlorella</i> , sperm
4	6.5-7.0	pAPG	<i>Anacystis</i> , sperm
5	12.0-14.0	pT	Sperm

Electrophoresis was carried out at 4° C. in citrate buffer pH 3.5 and voltage gradient 15 V./cm. for 2 hr. pC, deoxycytidylic acid; pAPC, dinucleotide of deoxyadenylic and deoxycytidylic acids; others are similarly assigned. No sequence of nucleotides is indicated in the case of dinucleotides. The ratio of two bases in the case of dinucleotides was found to be approximately unity.

deoxyribonucleic acid with deoxyribonuclease in the dialysis tube showed that the core, that is, non-dialysable fraction in the case of sperm deoxyribonucleic acid, contains 36-40 per cent of the original deoxyribonucleic acid whereas in the case of *Anacystis* and *Chlorella* it is only 18-20 per cent. In separate experiments deoxyribonucleic acid was incubated with deoxyribonuclease similarly without dialysis and the hydrolysate was chromatographed¹². Three distinct bands were detected under ultra-violet light and those were designated as band 1, 2, 3 according to their higher migration in the chromatogram. The first band was analysed after elution with 0.1 N hydrochloric acid. Molar proportion of bases in the first chromatographic band of hydrolysate and in the core is given in Table 1. In all the samples the ratio of purine to pyrimidine is higher both in the first band and the core. The third chromatographic band was subjected to electrophoresis¹³ in citrate buffer pH 3.5 and voltage gradient 15 V./cm. for 2 hr. using Spinco paper electrophoresis apparatus. It was observed that the third band after electrophoresis was separated into four spots in the case of *Anacystis*, three spots in the case of *Chlorella* and five spots in the case of sperm. The spots were designated as 1, 2, 3, 4 and 5 according to their higher electrophoretic mobilities. The electrophoretic mobilities of the spots and their probable identities are given in Table 2. Spot 4, which has been identified as dinucleotide of deoxy-adenylic and deoxy-guanidylic acids, is absent in the case of *Chlorella*, indicating the occurrence of less adenine guanine linkage than that in *Anacystis* or sperm deoxyribonucleic acid. From this point of view sperm deoxyribonucleic acid differs from that of *Anacystis* in containing a distinct thymidylic acid spot in the third band. In short, it appears that the deoxyribonucleic acid of *Anacystis nidulans* contains more adenine-guanine linkages than that of *Chlorella ellipsoidea* and fewer thymidylic acid units than that of sperm. The analyses of other portions of deoxyribonucleic acid may reveal more differences in the

arrangement of the nucleotides in deoxyribonucleic acid of blue-green algae from those of other sources which have chemically identical composition.

Details of this work will be published elsewhere.

RADIOBIOLOGY

In vitro Uptake of Iodine-131 by Tissues of Rainbow Trout

RECENTLY, it has been shown that *in vitro* uptake of iodine-131 by the lactating mammary tissue of rat was 10-15 times that of liver, muscle or boiled mammary tissue. Further, the data on the *in vitro* uptake of iodine-131 by different tissues of rat indicate that iodide concentration mechanism in the mammary, salivary and gastric glands but not in liver or placenta appears to be similar to that of thyroid gland in the rat¹. In the case of fish, it has been shown that the thyroid hormone is not involved in the regulation of oxidative metabolism, and thus it was decided to study the *in vitro* uptake of iodine-131 by different tissues of rainbow trout (*Salmo gairdnerii*)². Tissue slices from one-year-old rainbow trout were incubated for 2 hr. at 13° C. in flasks containing 2 ml. Nandi and Bern medium³. The T/M values (counts per min. per 100 ml. tissue divided by counts per min. per 0.1 ml. medium) for different tissues were calculated.

The values of the ratio T/M for *in vitro* uptake of iodine-131 by different tissues of rainbow trout indicated that only thyroid follicles present in the lower jaw concentrated iodine-131. The T/M value was higher in the case of the posterior part of the lower jaw than the anterior part, indicating that the thyroid follicles are comparatively more numerous in the posterior part. Uptake of iodine-131 was higher in the lower part of the gill than the upper part and this may be due to the presence of some thyroid follicles at the base of the gills where they are attached to the lower jaw. Addition of thiouracil (0.02 mgm./ml.) to the medium did not affect uptake of iodine-131 by thyroid follicles, whereas potassium thiocyanate blocked such uptake by thyroid follicles. The T/M values for uptake of iodine-131 by different organs of the digestive system, kidney, head kidney, liver, spleen, heart muscle, skeletal muscle or brain were less than 1.0, indicating that these organs or tissues have a relatively poor ability to concentrate iodide *in vitro*.

PHYSIOLOGY

Protein and Lipid Content of *Chlorella vulgaris* in Relation to Light

INCIDENTAL to other work, we have observed an effect of light on *Chlorella vulgaris* which can be interpreted as indicating an influence of different spectral regions on the synthesis of protein and lipid.

A strain of *Chlorella vulgaris* which has been maintained in this laboratory since 1938 was cultured in an inorganic medium consisting of potassium nitrate, 0.025 M; crystalline magnesium sulphate, 0.02 M; potassium dihydrogen phosphate, 0.018 M; crystalline ferrous sulphate, 0.00005 M; and potassium citrate, 0.00005 M. Air, enriched with 5 per cent carbon dioxide, was bubbled through the culture solutions continuously. Duplicate sets of flasks, with an initial population of 100 cells/mm.³, were illuminated continuously at a total incident radiation of 600 foot candles, as measured with a Weston illumination meter, model 603. Illumination for one set was provided by daylight fluorescent lamps and for the other set by tungsten filament lamps.

The wave-length distribution of the radiation was such that, although both sets of cultures received equal total amounts of incident visible radiation, the 'filament' cultures received one-half as much radiation as the 'fluorescent' cultures in the 440–455 mμ region of the spectrum (60 f.c. vs. 120 f.c.) and twenty times as much radiation in the 655–700 mμ region (71 f.c. vs. 3.55 f.c.). Despite the differences in the ratio of red to blue intensities incident on cultures under these light sources (1.18 for the 'filament' and 0.029 for the 'fluorescent'), the total incident radiation

in the two regions combined was about the same for both sets of cultures (131 foot candles for the 'filament' and 123.55 for the 'fluorescent').

All cultures were maintained at $23 \pm 1^\circ \text{C}$.

Cell counts were made in duplicate for each culture at approximately 24-hr. intervals by means of a haemocytometer. Total packed volumes and dry weights were determined in the conventional ways at the end of each experiment (15 days). Total nitrogen and total protein were determined as described by Umbreit¹ and total lipid was determined by the method of Stekol *et al.*²

Table 1 shows that the final population achieved, total packed volume, and proteins formed were substantially greater in cultures exposed to the filament source than in those exposed to the fluorescent source. However, the yield of lipid (expressed as per cent of dry weight) was lower in the 'filament' than in the 'fluorescent' cultures. But, despite the difference in percentage yield of lipid, the yield in absolute terms was about 3.4 times greater in the 'filament' cultures because of the greater total growth (2.28 mgm. of lipid/ml. of culture versus 0.67 mgm./ml. of culture).

Table 1. RELATION OF CERTAIN CELL CHARACTERISTICS TO LIGHT SOURCE IN *Chlorella vulgaris*

Characteristic (15-day culture)	Light source		Filament Fluorescent
	Filament	Fluorescent	
Population (cells/mm. ³)	100,070	70,000	1.43
Packed volume (mm. ³ /ml.)	14.50	9.00	1.61
Dry weight (mgm./ml. of culture)	10.31	2.31	4.46
Total protein (per cent of dry weight)	49.86 $\pm$ 5.23	39.64 $\pm$ 5.41	1.26
Total lipid (per cent of dry weight)	22.2 $\pm$ 2.89	29.0 $\pm$ 1.82	0.76
Total carbohydrate (by difference)	26.48	25.55	1.04

The differences in protein and lipid contents of cells grown under the two different light sources are clearly significant within 95 per cent confidence limits. The critical ratio of protein from 'filament' versus 'fluorescent' cultures was 4.48 (t 0.05 = 2.086). The corresponding value for lipid content was 3.96 (t 0.05 = 2.048).

Peaks in photosynthetic efficiency occur in the 440–455 mμ and in the 650–700 mμ regions³; but what effect, if any, these wave-lengths may have on subsequent biochemical conversion of the primary products of photosynthesis is not known. The present experiments show that, with the light sources and total radiation employed, the relative protein content is higher and lipid content is lower in *Chlorella vulgaris* cultured under light conditions relatively deficient in the 440–455 mμ region and distinctly richer in the 650–700 mμ region (filament source) than in cells exposed to a light source that is rich in the blue wave-lengths and relatively deficient in the longer wave-lengths. However, the experiments do not indicate which of these regions is more important in determining the protein and lipid contents and the protein/lipid ratio in the cells or whether the determining factor is the ratio of blue to the longer wave-lengths or, indeed, whether other wave-lengths have an important role. These facets of the problem are being investigated.

Two-dimensional paper chromatography showed no qualitative difference in the amino-acid content of

protein from 'filament' and 'fluorescent' cultures. Alanine, arginine, aspartic acid, glutamic acid, glycine, *isoleucine*, leucine, serine, threonine, and valine were identified in the protein from both sources.

Interaction between Repetitive Nerve Stimulation and Twitch-potentiating Agents at the Neuromuscular Junction

THE indirectly developed maximal twitch tension of vertebrate muscle is sometimes augmented after periods of tetanic nerve stimulation, an effect generally called post-tetanic potentiation. This effect is further increased by the administration, prior to tetanic conditioning, of physostigmine in doses which in themselves are too small to facilitate twitch tension¹. Physostigmine² and also other agents which elicit twitch potentiation, for example neostigmine³ and *m*-hydroxy phenyltrialkylammonium ions⁴, have been shown to possess an action on motor nerve terminals which is revealed by bursts of repetitive antidromic nerve discharge appearing after single orthodromic volleys. Furthermore, this presynaptic activity is greatly facilitated by tetanic conditioning of the motor nerve⁵. Within the context of these observations, it seemed important to compare drug-induced twitch potentiation before and after periods of repetitive motor nerve stimulation.

Drugs dissolved in isotonic saline were injected into the arterial supply of the cat gastrocnemius muscle before and at different intervals after a 10–20 sec. period of motor nerve stimulation at frequencies of 50–400/sec. Except for these periods of tetanic conditioning, the nerve was stimulated by single supramaximal shocks at a rate of 1 every 6 sec. Antidromic nerve discharge was displayed on a cathode-ray oscilloscope. A monopolar recording electrode was placed on an *L7* ventral root filament and an indifferent electrode on the skin. All cats were anaesthetized with chloralose. Two groups of drugs were used as test agents. Group I comprises *m*-hydroxy and *p*-hydroxy phenyltrialkylammonium ions and neostigmine; Group II consists of phenyltrialkylammonium ions and a variety of aliphatic quaternary ammonium ions including tetraethylammonium. A characteristic feature of Group I agents is the perfect correlation exhibited between their twitch-potentiating potencies (on single shock stimulation) and *in vitro* anticholinesterase activities⁶. The Group II compounds lack such a correlation and most of them are relatively much weaker than the other agents as either twitch potentiators or cholinesterase inhibitors. In contrast to Group I agents, the compounds of Group II rarely elicited post-activation antidromic motor nerve discharges; they did, however, regularly produce this neural response after 10-sec. periods of tetanic conditioning (200 per sec.) or on stimulation every 7 sec. with paired shocks separated by 1–3 msec., conditions which also facilitate

the post-activation neural response to Group I agents⁷.

In twenty nerve-muscle preparations, consistent results were obtained when agents of Group I and Group II were injected after periods of tetanic stimulation: drug-induced twitch potentiation greatly exceeded that obtained in response to equal, or smaller, doses administered prior to the tetanic conditioning. A characteristic result is illustrated in Fig. 1. Repeated administration of a test dose at different intervals after tetanic conditioning permitted determination of time course and duration of the post-tetanic enhancement of pharmacological response. Using *m*-hydroxy phenyltriethylmethylammonium and its non-hydroxy analogue as test agents, enhancement of drug-induced twitch potentiation in 8 different nerve-muscle preparations endured for 10–80 min. after one conditioning tetanus (200/sec. for 20 sec.). In 5 of these preparations, the time of return to pre-tetanic drug response exceeded 20 min. The maximal pharmacological effect was always produced by the first post-tetanic injection of drug, usually made within 30 sec. after cessation of the tetanus. From then on, the effect decayed in an

Fig. 1. Effect of *m*-hydroxy phenyltrimethylammonium ion on isometric twitch tension before and after tetanic conditioning. Chloralosed cat. Single maximal shocks applied to posterior tibial nerve every 6 sec. as square waves of 0.5 msec. duration; marks at bottom of trace indicate time of injection. Top, Response to test agent, 1 μ gm./kgm. intra-arterially; middle, response to test agent, 5 μ gm./kgm. intra-arterially; bottom, response to test agent, 1 μ gm./kgm. intra-arterially after tetanic nerve stimulation at 300 sec. for 20 sec. Note that injection was made during a post-tetanic depression of twitch tension.

Fig. 2. Effect of phenyldiethylmethylammonium ion on isometric twitch tension before and at various intervals after tetanic conditioning. See legend to Fig. 1 for technical details. All injections were 50 μ gm./kgm. intra-arterially. Note that first injection of test agent after tetanus (20 sec.) was given during post-tetanic potentiation of twitch tension. Not shown here is response to test agent 75 min. after tetanus; this response was same as shown in top tracing.

exponential manner until the pre-tetanic level of response was attained (Fig. 2).

This increase in pharmacological response produced by tetanic conditioning was observed irrespective of whether the post-tetanic twitch tension in the absence of drug was potentiated, depressed or unchanged relative to pre-tetanic tension. This increase is, therefore, not contingent on the selection of stimulus parameters which result in post-tetanic potentiation *per se*.

The duration of enhanced drug-induced twitch potentiation observed after tetanic conditioning is considerably longer than that of other post-tetanic phenomena previously studied: decurarization^{7,8},

increase in miniature potential discharge-rate⁹, twitch potentiation¹. These latter events, subsiding within 5–10 min. at the most, have been attributed to an action on presynaptic terminals which augments transmitter output^{8,9}. The increased drug-induced twitch potentiation seen after repetitive nerve stimulation also appears to have a presynaptic origin; this suggestion is supported by the finding that twitch-potentiating compounds, including those which are not cholinesterase inhibitors, produce a post-activation antidromic motor nerve discharge which is markedly facilitated in frequency and duration by tetanic conditioning. Perhaps the post-tetanic increase in pharmacological response constitutes a more sensitive measure of the duration of presynaptic changes consequent to repetitive nerve stimulation than is provided by changes in miniature potential discharge-rate, post-tetanic decurarization and twitch amplitude. Alternatively, the post-tetanic increase in drug-induced twitch potentiation may result from changes in neuromuscular transmission which are unrelated to these other more transient post-tetanic phenomena.

In the absence of further information concerning the nature of the presynaptic alterations involved, we may conclude that the effects of repetitive nerve stimulation and of twitch-potentiating compounds on presynaptic terminals are interchangeable and additive.

Locating Capillary Microelectrode Tips within Nervous Tissue

For the identification of structures generating potentials recorded by micropipettes it is necessary to locate the position of the micropipette in the tissue. The method most frequently used to obtain this information consists in depositing a marker at the tip of the micropipette. Most authors employ an electrolyte of good conductivity the composition of which does not disturb the functions of the cells but which leaves a trace when a small amount of it is extruded from the electrode by electrophoresis. Thus, crystal violet in hydrochloric acid¹, lithium carmine in potassium chloride², silver nitrate³ and potassium ferrocyanide^{4,5} have been used for markings in the retina, whereas gold trichloride in potassium chloride (von Baumgarten, R., personal communication) and ferrous ammonium sulphate⁶ were used

Fig. 1. Frozen sections, 100 μ , according to the plan of the penetrating electrode. Hematoxylin-eosin stain. A, Single mark in cat cortex (suprasylvian gyrus); B, multiple marks in pigeon telencephalon; left, two sites of marking at 1 mm. distance; right, three sites at 0.5 mm. Index: 1 mm.

for the central nervous system. To our knowledge, none of these methods is used routinely. This is probably due to the irregularity of the results and also to the difficulty of finding the very small mark left in the tissue.

To obviate the above-mentioned difficulties, we have devised a method in which the extruded marking ions are complex anions containing copper and citrate. The advantage of complexing the copper is that a too drastic fixation of copper on to the proteins of the nervous tissue is thereby avoided. It is well known that if a solution of a simple salt of a heavy metal is used as an electrolyte, the release of metal cations provokes a considerable and almost immediate increase in the electrode impedance. This inhibits the current-flow, and, in most cases, the result is that the coagulated proteins adhere to the tip of the micropipette, so that it is impossible to remove the marking deposit. If, however, the copper is complexed, the impedance of the electrode remains constant during the entire time of current-flow and the tip of the electrode remains clean, no coagulum being seen on inspection under the microscope.

In practice we use an electrolyte containing complex anions of copper and citrate, obtained by dissolving 811 gm. (2.5 moles) of tripotassium citrate monohydrate and 213 gm. (1.25 moles) of cupric chloride dihydrate in 1 litre of water and adjusting the pH to 7 with the necessary amount of strong potassium hydroxide solution. In the 0.5, 1.5 μ micropipettes (4–40 M Ω) this solution can be conveniently substituted for the electrolytes (potassium chloride, sodium chloride) generally used for the detection of spikes. (We are grateful to Prof. P. Souchay (Department of Chemistry, Sorbonne, Paris) for his advice on the preparation of complex ions.)

After recording, the marking is obtained by passing a continuous 2- μ amp. current with microelectrode negative, for 2 min. The specimen is then fixed in 10 per cent neutral formal and embedded in paraffin (or sliced frozen). Nissl or panoramic staining is then carried out by the usual techniques. The method was tested on pigeon and cat brains. In both cases, after staining the tissue, a well-defined, colourless ring appears, having a diameter varying with the preparation from 300 μ to 800 μ . Examination of serial sections shows that this ring results from the

cutting of a sphere (or ellipsoid), the centre of which is the tip of the electrode. When the section passes through a diametrical plane, a colourless spot having a diameter of 50–100 μ likewise appears in the centre of the ring. An examination at higher magnification shows that the absence of staining in the ring and in the centre corresponds to tissue lysis, due probably to denaturation of the proteins by the copper. This assumption is supported by the fact that perfusion with an acidified Ringer solution before killing the animal prevents the formation of the ring whereas an alkaline perfusion favours it. It is known that metal-protein bonding is facilitated by an increase in pH. We think that the formation of the ring around the central point is due to a passive diffusion of the product after its release from the tip of the electrode, since the intensity of the current and the time of its application have little influence on the diameter of the sphere.

It seems to us that this method is likely to be useful to neurophysiologists for the following reasons:

- (1) Its simplicity: the classical routine histological methods can be used without modification.
- (2) The marks can be easily found, and, because of the presence of the halo around the central point, are not liable to be confused with artefacts.
- (3) Its reliability: whereas many methods give very irregular results, we have found that with this method the number of failures is very small.

We hope that an extensive use of this method will confirm these results.

Mechanisms of Nerve Impulse Initiation in a Pressure Receptor (Lorenzian Ampulla)

ELASMOBRANCHS have a well-developed system of large tubular sense organs, the Lorenzian ampullae^{1–4}. In the dogfish, each ampulla consists of a bulb-like swelling, about 0.7 mm. in diameter, located deeply in the head of the fish, and a jelly-filled tube, several mm. long, that opens in a skin pore (see inset of Fig. 1). The ampulla is innervated by a bundle of 4–8 nerve fibres that end inside the swelling. Since the findings of Sand⁵ and Hensel⁶ that the stationary frequency of impulses discharged by the Lorenzian ampulla has a high temperature coefficient ($Q_{10} = 2-3$), the organ has been generally regarded as a thermo-receptor. But at that time, it was not yet known that not only thermo-receptors but also mechano-receptors may have such a high temperature coefficient without losing their mechano-receptor specificity^{7,8}. The general morphology of the Lorenzian ampulla suggests a mechano- rather

than a thermo-receptor function. In any event, its deep location in the head, and the relatively low thermal conductivity of the jelly of its tube, argue strongly against its being a thermo-receptor. In fact, Murray⁹ has recently shown in *in situ* experiments that probing of the ampulla pore with a bristle causes a brief change in the frequency of the nerve impulses discharged. In this communication evidence will be given that the ampulla is sensitive to pressure; it produces generator potentials which increase with the internal pressure of the ampulla.

Single isolated ampullae of the dogfish (*Mustellus canis*) were set up in a pressure chamber (Fig. 1). The tubule was cannulated and connected to a pump. Thus, the internal and/or external pressure of the ampulla could be varied over a wide range. Single axons were dissected up to the point of axon emergence from the ampulla, and the electrical activity led off that point. Under these conditions generator and action potentials of the order of 0.1 mV. are recordable.

When the internal pressure of the ampulla is raised above its external pressure, generator potentials are produced. The amplitude of the generator potential increases with the pressure differential. The relation between pressure and generator potential is best seen when the site of nerve impulse initiation is blocked by an anaesthetic¹⁰. This prevents the generator current from being short-circuited at that site, and the generator potential is found to increase over a wide range of pressure (Fig. 2).

In the non-anaesthetized preparation the effect of an increment in generator current is to increase the frequency of nerve impulses. At normal atmospheric pressure on either side of the ampulla, relatively few units produce generator potential sufficiently large to set up nerve impulses. But as the internal pressure is raised, the generator potential is driven to the critical firing-level, and impulses are discharged rhythmically and continuously. When the internal pressure is raised abruptly to a new level, the discharge has a dynamic and a static non-adaptive phase. The frequency of both phases increases as a function of the pressure differential (Fig. 2).

The structures that convert pressure into generator potentials are located inside the ampulla swelling. The ampulla tube and most of the tissue of the ampulla swelling can be removed by micro-dissection¹¹

Fig. 1. The Lorenzian ampulla is drawn over a metal cannula (c). Its internal and/or external pressures are varied and the corresponding generator and action potentials are led off a single axon with electrodes E_1 and E_2 . Inset, some anatomical characteristics of an ampulla. P, Pore; T, tubule; A, ampulla swelling which contains the receptor endings; N, bundle of 4-8 nerve fibres.

Fig. 2. Generator potential and impulse frequency as a function of pressure. The internal pressure of the ampulla is varied at constant external pressure of 1 atmosphere, and the pressure differential (abscissa) is plotted against the amplitude of the resulting generator potential and impulse frequency (static phase). Generator potential and impulse frequency were determined in successive runs. In order to obtain a complete pressure-generator potential curve, uncomplicated by action potentials, the latter were abolished with procaine (0.08 per cent). Inset, response patterns of generator and action potentials at a, 40 cm. and b, 95 cm. pressure differential. Calibration, 50 μ V.; 25 msec.

without impairment of the convertor process. The generator potential originates in, or in the immediate neighbourhood of, the nerve terminals, at a site more peripherally located than that at which the nerve impulse is started. This situation resembles that of other mechano-receptors¹¹⁻¹⁴. The generator structures are excited effectively by an increase in the internal ampulla pressure that involves stretching, but not by increasing equally and simultaneously the internal and external pressures. A change in temperature causes an increase in the rate of rise of the mechanically elicited generator potential and thereby causes an increase in impulse frequency. But a temperature change, *per se*, produces no excitation: if the internal ampulla pressure is low so that no detectable generator potential is produced, a change in temperature, however steep its gradients, elicits no electrical response.

The Lorenzian ampulla may thus possibly serve as a receptor of hydrodynamic pressure. In the dynamic phase of impulse discharge, the sensitivity of the receptor at about 10 metres of water (the normal cruising range of the fish) is from 5 to 12 impulses/second per metre of water pressure.

Elevated Serum Insulin associated with Leucine-induced Hypoglycæmia

SINCE the original description of leucine-induced hypoglycæmia in 1956¹, much interest has been aroused concerning the mechanism by which the administration or ingestion of L-leucine or leucine-containing proteins produces a profound lowering of blood sugar-levels in susceptible individuals. Our previous experiences with two leucine-sensitive children have been reported in detail elsewhere^{2,3}; the present communication deals with new and pertinent observations.

Payne and Woolf⁴ reported a high blood-level of insulin-like activity following administration of leucine when compared to a fasting-level obtained a few days previously. Drs. Renold and Steinke of Boston and Drs. Yalow and Berson of New York have kindly determined for us the levels of insulin-like activity using the epididymal fat pad method⁵ and the level of circulating insulin by an immunochemical technique⁶, respectively.

In these experiments the L-leucine was injected intravenously² at a dose of 75 mgm./kgm. Zero time on Figs. 1 and 2 represents the end of a 2-hr. fasting period at which time the leucine was given. Blood samples were drawn serially during the subsequent hour. Sugar-levels were obtained for capillary blood using the method of Nelson-Somogyi⁷. Sera from venous blood were used for the determination of insulin and insulin-like activity-levels.

In Fig. 1 is shown the levels of insulin-like activity obtained by the method of Renold. The stippled bar along the ordinate indicates the limits of the values obtained in Renold's laboratory in ten normal infants less than two years of age. The maximum level was 1,450 micro-units and the mean level was 513 micro-units per ml. of serum. The solid black circles represent the results obtained on a control patient. There was no effect on the blood sugar-level (92 mgm.-86 mgm. per cent) or on the insulin-like activity. The

Fig. 1. Blood insulin-like activity following L-leucine administration. Method of Winegrad and Renold (ref. 5)

Fig. 2. Blood insulin-levels following L-leucine administration. Method of Yalow and Berson (ref. 6)

interrupted lines depict results obtained on two occasions on patient 1 (J. C.). At 19 months of age there was an increase in insulin-like activity to a level slightly above the normal range and the blood sugar-level was decreased from 84 mgm. to 38 mgm. per cent. When the test was repeated two months later, the insulin-like activity was unaltered during the course of the experiment although we observed a decline in the blood sugar-level. The solid lines depict our experiences in patient 2 (R. L.). The first test, at 32 months of age, demonstrated a significant increase in circulating insulin-like activity and the blood sugar-level decreased from 38 mgm. to 6 mgm. per cent. One month later, a second test again demonstrated a marked increase in insulin-like activity concomitant with a fall in the blood sugar-level.

In Fig. 2 are shown levels of insulin obtained by Yalow and Berson on aliquots from the same specimens from which the data on Fig. 1 were obtained. The stippled bar along the ordinate indicates the normal insulin-levels obtained by the immunochemical technique which range from virtually zero to 66 micro-units per ml. of serum. A control patient is again represented by solid circles. There was no change in either blood sugar-levels or in the circulating insulin-level during the 1-hr. test period. Patient 1 (J. C.) showed no significant changes in insulin-levels on two occasions. Patient 2 (R. L.) demonstrated very dramatic increases in circulating insulin-levels on each occasion.

Thus, we have demonstrated a significant increase of both insulin and insulin-like activity on duplicate samples of serum on two occasions in one patient with leucine-induced hypoglycæmia following the intravenous administration of leucine. In each instance there was an appropriate decrease in the blood sugar-level. In the other patient, there was no demonstrable change in the insulin-level on either of

two occasions, and the insulin-like activity was increased on only one of the two times measured.

Although we have demonstrated marked leucine sensitivity of each patient on repeated occasions, we are unable to explain the difference between these two patients with respect to the response of circulating insulin and of insulin-like activity to the administration of leucine. Other investigators have obtained data showing an increase in circulating insulin-levels in three other children with leucine-induced hypoglycaemia after the administration of leucine. These results have been communicated to us by Yalow and Berson, in whose laboratory the analyses of insulin-levels were performed. A rise of "insulin or insulin-type activity" after the administration of leucine has been reported in yet another child⁸.

It would appear that in the majority of children sensitive to leucine the blood-sugar depressant activity of this amino-acid is mediated via increased synthesis and/or release of insulin. The exact mechanism by which leucine increases the circulating insulin-level is unknown. It is remarkable that in one of our two patients, hypoglycaemia followed the administration of leucine without an associated significant increase in insulin-level. The discrepancy may be explained by the presence of circulating insulin in a 'bound' form not readily detectable by the techniques employed. Other possible explanations also are now being tested.

This investigation was supported in part by research grants from the National Institutes of Arthritis and Metabolic Diseases (A-3581 (A)) and Mental Health (M-2673), U.S. Public Health Service.

ANATOMY

X-ray Diffraction Study of Acellular Teleost Bone

THE osseous endoskeletons of the higher orders of teleost fish are noteworthy in that they are totally devoid of enclosed osteocytes (Fig. 1)^{1,2}. The osseous tissue of other fish, like that of all other vertebrates, contains enclosed osteocytes. Although acellular bone, *per se*, is phylogenetically a very ancient tissue³, its appearance as the sole osseous element in the skeletal systems of the most highly evolved and successful fish suggests that possession of such a tissue confers an adaptive value to the organism in a marine environment.

Fig. 1. Operculum of the zebra fish (*Pterois volitans*), a typical acellular bone form. Note the absence of enclosed osteocytes. ($\times 450$)

A taxonomic classification of the distribution of these two bone tissue types in fish is under way. Preliminary observations by Moss⁴ indicate that the classification of K  lliker¹ and of Berg⁵ require further study.

The histogenesis of acellular bone is also unusual. The osteoblastic cells become incorporated within a matrix of their own production. There is an almost immediate cellular necrosis following which the cell spaces totally disappear, becoming filled with a substance indistinguishable from that of the surrounding calcified matrix. A more complete description of the osteogenic and reparative processes of this tissue will be published elsewhere.

An X-ray diffraction study was undertaken to seek further information on the structure of piscine bone. Two fish were used, Spanish mackerel (*Scomberomorus maculatus*) which has acellular bone, and the carp (*Cyprinus carpio*) which has cellular bone tissue. The skulls of several adults of each species, freshly caught, were soaked in water, scraped and cleaned. The separate samples were pulverized in a Waring blender and dried over calcium chloride. The material was then ground by hand in a mullite mortar for X-ray diffraction examination.

The X-ray diffraction powder patterns (Fig. 2) were taken on a 'Norelco' diffractometer using nickel-filtered copper K-radiation, with a 1-deg. slit system, and an argon-filled Geiger-M  ller counter as a

Fig. 2. Comparison of X-ray diffraction powder patterns of acellular (Spanish mackerel) fish bone (upper) and cellular (carp) fish bone. Nickel-filtered copper K-radiation was employed. The broad peak on upper pattern at about 20   2   is probably due to a large collagen component in the acellular bone

detector. The latter was set to travel through the goniometer arc at a speed of $\frac{1}{2}^\circ$ 2 θ per min.

Fig. 2 shows typical X-ray diffraction patterns of the two specimens. Both patterns indicate the presence of a finely divided hydroxyapatite phase. The apatite crystals in the acellular bone (upper curve) appear to be smaller and/or more strained than the cellular bone crystals (lower curve) as evidenced by the broader X-ray diffraction maxima due to apatite seen at about 26° 2θ , 29° 2θ , and 32° 2θ . There is a much larger organic fraction, probably collagen, in the acellular bone than in the cellular bone. This is shown by the prominent, broad peak at about 20° 2θ which appears in the acellular pattern but not in the cellular X-ray diffraction pattern.

The role of acellular bone in the mineral homeostasis of the fish and the structure of such bone is being further investigated⁶.

This work was aided, in part, by Grants A-1930-C and D-572, National Institutes of Health.

A Microscopic Method of determining Rates of Bone Growth

THE measurement of accretion-rates of bone by a non-toxic, non-radioactive, direct method based on the intravital marking of growing surfaces would be of value¹. I have been studying intravital staining of growing-bone surfaces in man, dogs, and rats, using many agents including alizarin red S, chlorazol fast pink², chlorazol sky blue, calcium fast purple, naphthamine brilliant blue RR and the tetracyclines. My aim was to be able to define microscopically the amount of growth in a stated time interval. By far the most satisfactory are the tetracyclines. Chlor-tetracycline, oxytetracycline and tetracycline are selectively incorporated into new bone deposits and can be identified by their fluorescence. They remain detectable for at least six months³.

Fig. 1 shows the growth of two canine osteons over a twelve-week period. The outer ring in each system is a deposition of alizarin red S, which is less suitable for this work than tetracyclines because of its systemic toxicity. Next is a chlortetracycline ring (33 mgm./kgm. intravenously given four weeks later). The next ring is a marker of oxytetracycline (62.5 mgm./kgm. intravenously, 8 weeks after the alizarin). The last line is made by 33 mgm./kgm. intravenously of chlortetracycline 12 weeks after the alizarin and 72 hr. prior to killing the animal. The

Fig. 1

upper system in the illustration demonstrates growth varying from 28 to 60 microns during the first four-week period, from 28 to 52 microns during the second, and from 26 to 48 microns during the third.

The width of the line of initial uptake may be wider than the subsequent width of that line (compare the second and fourth lines, which both result from a dose of 33 mgm./kgm.). The relationship of this to changes occurring in the osteoid and at the calcification front is not yet known.

Ghosez⁴ and Ponlot⁵ have shown that the microscopic localization of tetracycline uptake is strongest at the peripheral portion of the pre-osseous layer, that is, the calcification front and region just preceding it.

The submicroscopic specific site of tetracycline uptake is unknown. However, so long as measurements are made between two tetracycline lines, this information is not required for measurements of the area of new bone deposit.

62.5-80 mgm. of tetracycline intravenously produce less-suitable lines because of their width and the flare that accompanies more intense deposits. Moreover, these doses may produce a partial inhibition of mineralization (unpublished work). Chlortetracycline, but not oxytetracycline or tetracycline, can occasionally produce a minimal decrease in mineralization of canine bone at doses as low as 33 mgm./kgm. intravenously. Therefore, 20 mgm./kgm. intravenously of oxytetracycline is recommended for work with dogs. In recent experiments with rats, demethyl-chlortetracycline showed greater intensity of fluorescence than identical doses of the other three. This may be related to its sustained blood-levels. A satisfactory mark is given in human bone by two oral doses of 1 gm. of any of the tetracyclines, 6 hr. apart.

Undecalcified sections must be used, since the tetracyclines are removed by acid or ethylenediamine tetraacetate. The width of the marker in thin transverse sections (less than 40 μ thick) is less than 8 μ for tetracycline doses of 33 mgm./kgm. intravenously, provided that the growing surface was reason-

ably perpendicular to the plane of section. This resolution exceeds that of calcium-45 (ref. 6) and radium (ref. 7), but not the optimum possible with plutonium-239 (ref. 8). The resolution and non-toxicity make this method preferable to lead⁹.

A high-pressure mercury vapour lamp, collecting lens and Wratten 18A filter provide a good source of ultra-violet light. Most ordinary bright-field microscopic equipment is satisfactory for this type of ultra-violet work. A Wratten 23A filter in the eyepiece reduces transmission of the blue auto-fluorescence of non-labelled bone and permits satisfactory black-and-white photography. More details on the ultra-violet microscopy are given in a paper by Kuper and May¹⁰.

Chlortetracycline, tetracycline and demethylchlortetracycline were supplied by Lederle Laboratories Division of Cyanamid of Great Britain, Ltd., under the trade names 'Aureomycin', 'Achromycin' and 'Ledermycin', respectively. Oxytetracycline was supplied by Pfizer, Ltd., under the trade name 'Terramycin'.

PATHOLOGY

Cytochemistry of Nucleic Acids in Murine Lymphoma Cells infected with Polyoma Virus *in vitro*

INFECTION of cultures of milk-adapted P388D₁ murine lymphoma cells with polyoma virus produces an alteration in the ribonucleoprotein (RNP) of the nucleoplasm, enlargement of the nucleolus, and intranuclear vacuoles containing abnormal RNP¹. Cytochemical studies of the late stages of infection of lymphoma cells *in vitro* with polyoma virus failed to reveal Feulgen-positive inclusion material¹. Since the infectivity of nucleic acid preparations from cells infected with polyoma virus appears to reside in the deoxyribonucleic acid (DNA) fraction², further attempts have been made to demonstrate abnormal DNA and to elucidate the relationship between changes in DNA and RNA or RNP metabolism in polyoma virus infection.

Three day-old cultures of milk-adapted P388D₁ lymphoma cells were infected with a 10⁻¹ dilution of the fourteenth serial passage of polyoma virus as previously described¹. The cells were examined at intervals of 24, 48, 52, 72 and 96 hr. after infection. Some modifications of the previous cytochemical staining procedures¹ were introduced. The intensity

Fig. 1. Nuclei of P388D₁ lymphoma cells stained with toluidine blue-molybdate (stage III). A-H represent stages in the evolution of the lesions. n, Nucleolus; i, inclusion; dn, degenerating nucleolus.

of staining was increased by a brief saline rinse before fixation. Hydrolysis of the Feulgen preparations for 30 min. gave more intense staining than the usual 10-min. hydrolysis. Cultures were also stained with acridine orange after fixation in absolute ethanol³.

Definite lesions were recognized 48 hr. after infection. The pathogenesis was assessed mainly from the time sequence of the changes, but in part by analysis of the increasing disorganization of nuclear structure (Fig. 1). Enlargement of the nucleus and nucleolus was the earliest change and this was accompanied by the appearance of homogeneous intranuclear zones or vacuoles filled with Feulgen-positive DNA (Figs. 1A and 2). These Feulgen-positive areas were also stained by toluidine blue-molybdate (TBM), stage III (ref. 4), after ribonuclease digestion. Later, an increasing number of cells with unstained vacuoles or ill-defined clear zones were noted (Figs. 1B and 2). Small round homogeneous inclusions then appeared in the vacuoles (Fig. 1C). The inclusions stained less strongly than the chromatin but were definitely

Fig. 2. One normal (top left) and two infected P388D₁ lymphoma cells, one of which (left) has an intranuclear vacuole filled with DNA, cf. Fig. 1, normal, A and B. Feulgen stain. (× 1,400)

Fig. 3. Intranuclear inclusion body. Feulgen stain. ($\times 1,400$)

Feulgen-positive (Fig. 3). Since the intensity of staining of the inclusions by TBM (stage III) was unaffected by ribonuclease digestion they did not contain any detectable RNA at this stage. Afterwards one or more of the enlarged nucleoli stained less intensely and became more diffuse (Fig. 1D). This nucleolar material formed one or more ill-defined masses (Fig. 1E) and eventually filled the clear spaces or vacuoles (Fig. 1F). The intensity of staining of the inclusions by the Feulgen procedure decreased during this period and the inclusions were more strongly coloured by TBM (stage III). Staining by TBM (stage III) was greatly reduced, but not abolished, by pre-treatment with ribonuclease, indicating that the inclusions contained RNA as well as DNA. Further nuclear disorganization was caused by shrinkage (Fig. 1G) and in many shrunken cells RNP could no longer be detected in the vacuoles (Fig. 1H). At this stage the inclusions were stained dark green by TBM (stage III) with or without previous ribonuclease digestion and were clearly Feulgen-negative (compare ref. 1, Fig. 9). The inclusions, therefore, no longer contained the nucleolar type of RNP which stains purple in stage III TBM preparations⁴. After very brief fixation (2 min.) in formol sublimate at 37° C., the inclusions stained intensely purple with TBM. In such preparations the inclusions were stained dark green after ribonuclease digestion and not at all after ribonuclease and crystallized deoxyribonuclease (Mann Labs. Inc.) digestion. All staining by TBM was prevented by extraction of nucleic acids with hot trichloroacetic acid. The inclusions could not be distinguished from other masses of chromatin in the acridine orange or in the pyronin methyl green preparations. Protein-bound amino and other groups were demonstrated in the inclusions by the ninhydrin-Schiff procedure¹. In the final stage of nuclear degeneration the thin circumferential wall of the vacuole ruptured and the inclusions could be seen in the adjacent cytoplasm.

The course of polyoma virus infection is interpreted as follows. The normal DNA of the chromatin breaks down to form amorphous Feulgen-positive DNA. DNA is not detectable in the next stage of infection, although it may exist as low molecular weight material which is not preserved by fixation. Inclusions containing DNA then appear and are surrounded by and incorporate RNA of nucleolar origin. As the RNA, and presumably the protein, of the inclusions increases they become less Feulgen-positive. Finally, nucleolar RNP can no longer be detected in the inclusions and they contain another form of RNA, DNA and protein. The failure to stain by the Feulgen procedure is probably caused by physical rather than chemical interference with the staining reaction by viral protein. A similar phenomenon has been observed

during the formation of vaccinia virus (Love, R., and Salzman, N. P., unpublished work); the cytoplasmic inclusion is strongly Feulgen-positive in the early stages of infection and becomes less so as the viral particles are formed.

We wish to thank Frances Y. Legallais and Roscoe H. Liles for valuable technical assistance and Joyce L. Sills for the drawings.

Leptospira pomona Infection in an Eastern Red Fox (*Vulpes fulva fulva*)

THE presence of leptospirosis in Pennsylvania cattle has been well established¹⁻³. An epizootiological investigation to determine the relationship between bovine and sylvan leptospirosis is at present being undertaken in south-eastern Pennsylvania. Infected cattle herds are identified and their premises intensively trapped for wild-life. Trapped animals are examined for infection by serological and cultural techniques. Isolations of leptospires have been made from the following animals: woodchuck⁴, opossum, skunk, racoon and Norwegian rat. This communication is believed to be the first to report the isolation of *Leptospira pomona* from an eastern red fox (*Vulpes fulva fulva*)⁵. The fox was trapped on the premises of a known infected cattle herd. Prior to the start of trapping, *Leptospira pomona* had been isolated from cattle and from surface waters on this farm.

The fox was caught in a No. 2 coil-spring trap, removed from the trap and delivered to the Leptospirosis Laboratory, School of Veterinary Medicine, University of Pennsylvania. On delivery, the fox was euthanized in a carbon monoxide chamber. A blood specimen was obtained by severing the jugular vein and collecting the flow. One kidney was removed aseptically.

The kidney was ground with pestle and mortar and diluted to approximately a 10 per cent suspension with Stuart's base liquid medium ('Difco'). Two tubes of each of the following media were inoculated with 2-3 drops of kidney suspension: Fletcher's semi-solid medium containing 15 per cent horse serum; Chang's semi-solid medium⁶ (Hamilton, Montana, modification⁷) containing 10 per cent rabbit serum; Chang's semi-solid medium containing 15 per cent horse serum; and Stuart's semi-solid medium⁸ containing 10 per cent rabbit serum. Tubes were incubated at 29° C. and examined at 10-14 day intervals by dark-field microscopy.

Serum from the blood specimen was examined for antibody content by the microscopic agglutination test⁹, employing an antigen bank of eleven serotypes: *L. bataviae*, *L. pomona*, *L. autumnalis*, *L. ballum*, *L. canicola*, *L. icterohemorrhagiae*, *L. alexi*, *L. grippotyphosa*, *L. australis* A, *L. sejiro* and *L. hyos*.

Growth of leptospires was detected on day 34 post-inoculation. Organisms were present in one tube of each of the following media: Fletcher's semi-solid

medium containing 10 per cent rabbit serum, Fletcher's semi-solid medium containing 15 per cent horse serum, and Chang's semi-solid medium containing 15 per cent horse serum. Transfers were made into Fletcher's semi-solid medium containing 10 per cent rabbit serum and into Stuart's liquid base medium containing 10 per cent rabbit serum. Subcultures made at 10-20 day intervals were sent to the Leptospirosis Unit, Animal Disease Eradication Diagnostic Laboratory, United States Department of Agriculture, Ames, Iowa, for typing. They were identified as *Leptospira pomona*.

The microscopic agglutination test titres were: *L. pomona*—1:100; *L. autumnalis*—1:1,600.

BIOLOGY

Juvenile Hormone Activity in Micro-organisms and Plants

THE juvenile hormone of insects promotes larval development but prevents metamorphosis. Its presence in an immature insect ensures that when the larva molts it will retain its larval characters and not differentiate into an adult¹. Extracts with juvenile hormone activity were first prepared from the abdomens of male *Cecropia* moths by Williams². Afterwards active extracts were prepared from adult males and females of 6 families of Lepidoptera as well as from eggs, larvae and newly moulted pupae^{3,4}, from representatives of 6 other orders of insects including Dictyoptera, Orthoptera, Hemiptera, Coleoptera, Diptera and Hymenoptera⁴⁻⁷ and from various insect products, for example, royal jelly⁷, insect faeces⁸. Investigation of other groups uncovered substances with juvenile hormone activity in extracts of the adrenals of cattle⁹ and in many tissues of numerous invertebrates in 13 classes, including Hydrozoa, Anthozoa, Anopla (Nemertinea), Cheilostomata and Ctenostomata (Ectoprocta), Pelyceopoda, Gastropoda, Polychaeta, Oligochaeta, Malacostraca, Arachnida, Holothuroidea and Balanoglossida^{4,7}. The most active invertebrate sources were the eye-stalks of crustaceans (*Homarus* and *Carcinides*)^{4,7}, and the heads of polychaetes (*Nereis*)⁷. Juvenile hormone

activity was later demonstrated in many vertebrate tissues besides the adrenals including pituitary, kidney and thymus¹⁰ and lymphatic, parathyroid, thyroid, mammary and gastric mucin (Schneiderman, H. A., and Gilbert, L. I., unpublished observations).

All these active extracts prevented certain tissues of young insects from assuming their adult aspect, but did not interfere with growth itself. In pupae of Lepidoptera, Hemiptera and Coleoptera, local application of active extracts caused the pupal epidermal cells to lay down a second pupal cuticle while untreated cells nearby deposited normal adult cuticle^{2,3,5,6,11}.

The present communication reports the occurrence of juvenile hormone activity in extracts of several micro-organisms. Ether or chloroform extracts were prepared from whole ferments (that is, cells plus media) as well as from washed organisms. In those cases where non-synthetic media were used, the uninoculated medium itself was also extracted and tested after autoclaving. Extracts of more than 60 organisms were prepared and assayed for their juvenile hormone activity by the 'Polyphemus' wax test⁶ and by other procedures^{5,11}. The 'Polyphemus' wax test can detect juvenile hormone activity in extracts with 1/2,000th to 1/10,000th as much activity per gm. as oil extracted from male *Cecropia* moths, whereas the other tests are less sensitive. Extracts of 6 species of micro-organisms had juvenile hormone activity in both the 'Polyphemus' wax test and in at least one other test for juvenile hormone activity^{5,11}. These included a ciliate, a flagellate, two bacteria and two yeasts. A representative sampling of the results is recorded in Table 1.

Table 1. JUVENILE HORMONE ACTIVITY OF MICRO-ORGANISMS

Name	Type of extract	Percentage of positive tests	Activity
<i>Ochromonas malhamensis</i>	ether	45	++
<i>Tetrahymena pyriformis</i>	ether	18	+
<i>Euglena gracilis</i>	ether	0	0
<i>Chilomonas paramecium</i>	ether	0	0
Baker's yeast (fresh)	ether	25	+
Brewer's yeast (dried)	ether	100	++
<i>Saccharo myces</i> (eight other species or strains)	chloroform	0	0
<i>Schizosaccharo myces</i> (2 species)	chloroform	0	0

<i>Dipodascus uniuucleatus</i>	chloroform	0	0
<i>Debaryomyces dispersus</i>	chloroform	0	0
<i>Trichosporon pullulans</i>	chloroform	0	0
<i>Nadosia dongata</i>	chloroform	0	0
<i>Endomyces fibuliger</i>	chloroform	0	0
<i>Lipomyces liposifer</i>	chloroform	0	0
<i>Micromonospora</i> sp. (mycelium)	chloroform	65	+
<i>Strepto myces</i> (seven species or strains)	chloroform	0	0
<i>Escherichia coli</i> (washed cells)	ether	0	0
<i>Escherichia coli</i> (cell-free broth)	ether	75	+++
<i>Proteus</i> spp. (whole broth)	ether	75	+++

In the course of assaying various bacteriological media it was discovered that ether extracts of soy bean meal had juvenile hormone activity, indicating that juvenile hormone activity is not only found in lower plants but in higher plants as well.

Despite some efforts, no activity could be obtained from well-chilled diapausing pupae or from allatectomized male adults of *Cecropia*. Nor was activity found in lipid extracts of sponges and of numerous familiar animals such as the sea anemone *Metridium dianthus*, the long-necked clam *Mya arenaria*, the horseshoe crab *Limulus polyphemus* and many others. Activity also appeared to be absent from various vegetable oils such as castor oil, wheat germ oil, palm oil, coconut oil, peanut oil, corn oil, olive oil, linseed

oil and cotton seed oil as well as from bees wax, carnauba wax, paraffin wax and ceresine wax. It was also absent from most of the micro-organisms examined. This lack of activity did not seem to be due to the presence of inhibitors in the inactive preparations, for in most cases addition of inactive extracts to active extracts did not cause a loss of activity.

These results indicate that we are dealing with a group of substances which are widespread in Nature, but are probably not universal. Indeed, one would scarcely imagine insects adapting a universal and indispensable molecule as a hormone. It is nevertheless intriguing that substances that can mimic an insect growth hormone occur in protozoa, fungi and mammals. These findings support the opinion offered earlier^{6,12} that in many cases the development of humoral mechanisms involves not so much evolution of hormones as such, but more the evolution of target mechanisms which acquire a sensitivity to specific small molecules that may have been present from earliest times, and the development of systems that can ensure the timely production of appropriate amounts of these specific molecules. As Hisaw puts it, often "... it is not hormones which have evolved but the uses to which they are put. ..."¹³

We wish to express our thanks to Prof. George Holz of Syracuse University, who provided us with Protozoa for extraction.

The investigation has been supported in part by research grants from the United States Public Health Service.

A Possible Function of Phycoerythrin in Intertidal Red Algae

THE transmission of light in coastal waters is such that penetration is greatest in the blue-green and least in the red region of the visible spectrum¹. This has led to the view that the phycobilins, accessory pigments that give rise to the characteristic colour of red algae, are responsible for photosynthesis by these

plants because, unlike chlorophyll, the pigments readily absorb blue-green light². Evidence in favour of this theory of complementary chromatic adaptation has been obtained by Haxo and Blinks from experiments in which the action spectra of several marine red algae were found to show a fair correlation with the absorption curves of phycoerythrin and phyco-cyanin³.

Continuing recent work on the factors affecting the ecological distribution of certain red algae⁴, we have become interested in the way light influences the growth of sporelings of these plants, and have made some preliminary experiments using *Plumaria elegans* (Bonnem.) Schm., a shade-loving species which inhabits the lower mid-littoral zone. We have extracted the red pigment from this plant and find that it has an absorption curve characteristic of phycoerythrin (peaks at 500 and 550 mμ). It is, therefore, well able to absorb blue-green light, and if the theory of complementary chromatic adaptation holds in the case of *Plumaria* sporelings, they would use this light for photosynthesis. To test this we grew sporelings in filtered sea water enriched with Erd-Schreiber medium⁵, contained in glass vessels screened from the light source by weak solutions of phycoerythrin, prepared freshly each day. We measured the rate of growth of the plants by counting the number of cells produced by a crop of approximately 200 sporelings during a ten-day period, the method used being one already described⁶. Contrary to expectation, sporelings screened in this way grew at more than twice the rate of the control material.

Because of the instability of solutions of phycoerythrin, we carried out subsequent experiments using a screen 2 cm. thick of a weak sea water solution (0.2 p.p.m.) of the dye eosin yellow, which also has an absorption peak in the blue-green region (515 mμ). Over the very wide range of light intensities used, including some below and some above optimum value (315 lux), it was found that the screened sporelings had a much more marked rate of growth (see Fig. 1).

At first it seemed possible that the dye was protecting the sporelings by removing ultra-violet light inhibitory to their growth. However, this possibility can be excluded because the distribution of spectral energy of the source used, an 'Ekco Daylight' fluores-

Fig. 1. Cell production by *Plumaria* sporelings grown under an 'Ekco Daylight' fluorescent lamp at different light intensities: ●—●, unscreened; ○—○, screened with a sea-water solution of eosin yellow (0.2 p.p.m.) 2 cm. thick

cent lamp, showed very little energy in the ultra-violet region, and even this small quantity was further reduced by the glass vessels used in the experiment. Moreover, the very weak screening solution of eosin yellow had no measurable effect on the small amount that remained.

The possibility that the dye solution was enhancing growth simply by shading the sporelings is also excluded. For at sub-optimal light intensities, shading would obviously inhibit growth, whereas it was found that the screened sporelings grew faster at a light intensity as low as 30 lux. Furthermore, even at the highest light intensity used (1,250 lux) shading would influence growth to an insignificant extent because the very weak solutions of the dye only absorbed 2.2 per cent of the total light energy in the wave-band 390–700 m μ , and it can be estimated from Fig. 1 that more than 15 times this amount would have to be removed to account for the difference in growth between screened and control sporelings.

It therefore appears that both eosin yellow and phycoerythrin, as used under our experimental conditions, promoted the growth of the sporelings by protecting them from the inhibitory effects of blue-green light emitted by the fluorescent tube, a light source with a spectral energy distribution closely resembling that of daylight. Accordingly, it seems that the theory of complementary chromatic adaptation does not apply in the case of *Plumaria*.

It is hoped to publish a fuller account of this work in the *Journal of the Marine Biological Association*. We thank Dr. E. J. Denton for many valuable discussions.

Growth Movements of the Radicle of *Striga*

THE directional growth of the radical (haustorium) of the root parasite *Striga asiatica* (= *S. lutea*) is normally controlled by a chemotropic factor diffusing from the host plant root¹. The parasite seeds may be germinated by treatment with a solution in which the host roots (*Sorghum vulgare*, etc.) have been growing. In this case the radicle undergoes a fixed growth movement which is roughly spiral. A basically spiral movement is seen in about 40 per cent of seedlings. More usually the movement is reduced to a strong curvature in one plane followed by a period of more or less straight growth, or by apparently anomalous curvatures in any direction. By growing the seedlings in agar cultures, it was shown that the movements were not influenced by the orientation of the seedlings to gravity or by rotation on a klinostat, at least during the initial curvature, although with

Fig. 1. Average growth-rates (11 seedlings) of the fast-growing (—) and slow-growing (---) sides of the *Striga* radicle during curvature and subsequent straight growth

forces greater than gravity (up to 10g) a positive movement was superimposed on the fixed growth movement.

The initial curvature in one plane was used in studying quantitative aspects of the movement. For this purpose seedlings were grown in Petri dishes, growth and curvature being recorded throughout development using a camera lucida in combination with a low-power microscope. The culture dishes were housed on the microscope stage in a light-proof box fitted with removable flaps to permit observation.

An analysis of curvature revealed that this was always associated with an inhibition of cell extension on one side of the radicle, which gave rise to a divergence from a normal sigmoid pattern of growth which characterized the growth of the opposite side (Figs. 1 and 2A). The initial period, during which the growth-rates of the two sides was equal, represents a phase of general swelling of the embryo and the commencement of meristematic activity.

In attempting to determine the nature of the factor causing this inhibition, the effects of various anti-auxins on growth and curvature were tested. The anti-auxin 2 : 3 : 5-tri-iodobenzoic acid had a striking effect in reducing curvature, by eliminating the differential inhibition of cell growth on the inner side of the curve (Fig. 2). At a level of 1 p.p.m., 2 : 3 : 5-tri-iodobenzoic acid strongly reduced curvature while

Fig. 2. A, *Striga* seedling showing initial curvature of the radicle; B, effect of 2 : 3 : 5-tri-iodobenzoic acid (1 p.p.m.) on curvature

linear growth was only reduced by about 20 per cent. Jones *et al.*² record that 2:3:5-tri-iodobenzoic acid reduced geotropic response in rape and rye-grass, but this only occurred at a level which was markedly inhibitory to linear growth. At higher concentrations of auxin; the anti-auxins 2:4:6-trichlorophenoxy showed lateral expansion of cells and considerable reduction of linear growth.

Although the effect of 2:3:5-tri-iodobenzoic acid suggests that the curvature factor may be some form of auxin, the anti-auxins 2:4:6-trichlorophenoxy-acetic acid and 2:4-dichloroanisole, which are supposed to act competitively with auxin at the growth centres, did not selectively reduce curvature. This indicates that the curvature factor, if some form of auxin, must be protected from the competitive action of these anti-auxins. One possible explanation is that the factor may be transferred selectively from a bound form (which could be some auxin/protein association) to the receptive centres for the growth reaction, or that certain places in the growth system are reserved for the curvature factor. The comparative immobility of the curvature factor (that is, not being ordinarily influenced by gravity or rotation on a klinostat) would indicate an association with structural or immobile constituents of the cell. 2:3:5-tri-iodobenzoic acid, on the other hand, could act at some site before the growth centres, which would be in agreement with Lineweaver-Burk data on the action of 2:3:5-tri-iodobenzoic acid.

Growth curvatures in other roots are known to be associated with a marked inhibition of extension growth^{3,4}, and various considerations have led to the view that curvature does not result from a redistribution of polar auxin, but from the production of a specific growth inhibitor on one side of the root. Audus and Brownbridge⁵ tested the effect of indoleacetic acid on the geotropic curvature of pea roots (which are stimulated by low concentrations of auxin) and found that both the lower and upper sides of the roots were stimulated to grow faster by low concentrations of indoleacetic acid (that is, the inhibited lower side, in which the auxin-level would presumably be supra-optimal if this substance is the curvature hormone, was also stimulated). This indicates that the curvature hormone in pea roots is not indoleacetic acid, or differs in some way from externally applied indoleacetic acid. The action of the anti-auxin α -(1-naphthyl-methylsulphide) propionic acid in reducing curvature in these roots (Audus and Brownbridge⁵) is attributed to the action of this substance on some endogenous inhibitor which is not indoleacetic acid, and the general promotion of growth of pea roots by this anti-auxin, to its action on residual inhibitors in the cells. The fact that indoleacetic acid and this anti-auxin show mutual antagonism⁶ is now explained by competition at a site outside the growth centre.

Audus and Thresh⁷, using paper partition chromatography, found that 2:3:5-tri-iodobenzoic acid reduced in a striking way the level of alcohol-soluble indoleacetic acid in pea seedling tissues, and at the same time induced a negative geotropic response in the side

roots of the seedlings; although the possibility that this substance may not actually be indoleacetic acid is indicated by the work of Bennet-Clark *et al.*⁴ on the isolation of plant growth substances using starch column chromatography. This shows that a substance distinct from, but appearing like, indoleacetic acid in paper partition chromatography is present in root tissues.

Variations in Scopoletin in Leaves in Relation to Chloride Treatment of Tobacco

HIGH concentrations of sodium chloride in the soil have an adverse effect on the growth of the tobacco plant. Stunted plants, with thickened leaves containing large quantities of starch, have been reported, and the leaf colour also is affected¹. Thickening of the secondary xylem elements² is also attributed to the effect of high chloride concentrations.

Scopoletin, as well as being a normal constituent of tobacco leaves, has been found to increase markedly in the case of attack by the tomato spotted wilt virus³ and to be present in higher concentration in differentiating than in non-differentiating tobacco tissue⁴. Scopoletin also acts as an inhibitor of the enzymic destruction of indoleacetic acid and could thus itself act as a growth inhibitor by causing indoleacetic acid to accumulate beyond the stimulatory range⁵.

Using fluorescence under ultra-violet light, paper chromatographic studies^{6,7} of aqueous and methanolic extracts of oven-dried green tobacco leaves from plants, variety Hicks, grown in sand in the glass-

Fig. 1. Scopoletin in tobacco leaves in relation to chloride

house with concentrations of sodium chloride ranging from 0.5 to 6.0 milli-equivalents per litre in the applied nutrient solution, have shown that increased chloride in leaves of the same physiological age is associated with increased scopoletin (Fig. 1). Glass-house-cured tobacco leaves and field-grown cured leaf also show similar relationships in scopoletin and chloride content, and calculations based on the assumption that the spot area is proportional to the logarithm of spot content⁶ give concentrations of scopoletin varying approximately from less than two to one hundred and seventy times greater in the leaf with high-chloride than in one containing a low-chloride concentration.

The increase in scopoletin associated with a higher chloride content in the leaf may account for the typical morphological and anatomical effects produced both in the leaf and generally in the plant: the stunting (also noticeable in virus attack³) being due to the effect on the indoleacetic acid metabolism, and the thickening of the secondary xylem to increased concentrations of scopoletin at the site of the differentiating tissue. Scopoletin concentrations in the root and stem of tobacco plants under varying chloride treatments are being examined.

As scopoletin passes unchanged into the mainstream smoke on combustion of the tobacco⁸, it may be an important factor in tobacco quality as influenced by sodium chloride in the soil. Other factors which affect the nutrient balance, such as low potash content, also appear to favour the accumulation of scopoletin.

Function of the Osphradium in *Bullia* (Gastropoda)

Krijgsman and Brown¹ have recently described a technique for operating on fully extended and immobilized marine Gastropoda. We have now used this 'water-rigour' method on 124 individuals of *Bullia laevissima* (Gmelin) preparatory to severing their osphradial nerves in order to discover the function of the osphradium. The osphradium in Gastropoda is generally thought to be an organ of chemo-reception, though the evidence in support of this theory is far from satisfactory. Experiments such as those of Copeland² are not convincing in view of the crude techniques used. A few workers, notably Hulbert and Yonge³, have suggested that the osphradium may be concerned with the perception of turbidity; but no experimental data have been presented in support of this view, the only evidence being circumstantial. Detailed histological studies of the osphradium, such as those undertaken by Stork⁴, add little to the argument.

Of the 124 snails on which we operated, 52 did not recover and post-mortem examination revealed damage to the pallium and/or the dorsal pallial artery which passes just below the osphradium. When the remaining 72 snails were killed and dissected after the completion of our experiments, it was found that in some cases the osphradial nerve had not been completely severed, while in others nerves other than the osphradial nerve had been cut or damaged accidentally. The results of experiments on these snails were therefore disregarded. In only 13 cases was the operation completely successful, the osphradial nerve being entirely severed without damage to other structures. Of these 13 snails, 12 lived for more than a week in the laboratory and were offered food on each successive day.

Bullia laevissima normally lies half buried in the sand, under water, only the upper part of the shell and the siphon being visible. It can be caused to emerge actively from the sand if suitable food be placed in or near the water. (A detailed account of this behaviour is given elsewhere by Brown⁵.) However, individuals which have had the osphradial nerve severed fail to emerge, even when presented with their favourite food—the tunicate *Pyura*. Nevertheless such individuals will feed when placed on the food or touching it, indicating that failure to emerge is not resultant on a disinclination to feed, but rather indicates a deficiency in chemo-perception from a distance. We are therefore of the opinion that chemo-reception is at least the major function of the osphradium in this species.

CYTOLOGY

Number of Chromosomes in the Human Cell

CURRENT work with human chromosomes in many laboratories has resulted in the publication of numerous photographs of chromosomes of human cells both normal and abnormal. Almost all these have been obtained from cells which are selected at least to the extent that they are cells capable of undergoing mitosis one or more times *in vitro*. These cells are often subjected to physical conditions which might conceivably influence the process of mitosis, that is, temporary chilling, change of pH, etc. Further, in most cases the mitotic process has been disturbed intentionally by the use of colchicine.

Because of the possible significance of these factors, we feel that the accompanying photograph (Fig. 1) will be of interest. It shows an unstained, uncolchicized bone marrow mitosis obtained within minutes after aspiration from a 59-year-old female. There is clear representation of 46 chromosomes. The correspondence of this and other morphological details with those obtained using colchicine and tissue culture methods is to be noted. We feel this is

Fig. 1

important in that it demonstrates a lack of dependence of these characteristics on the use of tissue culture and colchicine.

Growth of the Gametes of *Amoeba spumosa* Grüber

In a previous paper¹ the biological cycle of *Amoeba spumosa* Grüber, the amoeba most often found in fresh water in Lombardy, was described and the cytological aspects of the gametes of this amoeba were studied by means of the electron microscope.

Fig. 1. Electron microscopical picture of a section of an *Amoeba spumosa* gamete. F, flagellum; G, Golgi apparatus; N, nucleus; V, vacuoles at the top end

These gametes (Fig. 1) are spherical cells, which move around by means of a flagellum, like those of *Amoeba proteus*: this observation confirms the forgotten observation of Jones². The flagellum has a structure common to the flagella of other organisms: that is, it contains nine peripheral filaments and two central filaments.

The present work was carried out to study these gametes statistically, in order to ascertain their developmental biology.

Amoebæ in gametogenesis, cultured under daylight (at 19° C.), release (Fig. 2) their gametes: in the following days it is possible to study the development of the released gametes. It is better to follow the growth of isolated gametes. In order to obtain quantitative data, we have studied isolated gametes, fixed with vapour, of a 2 per cent solution of osmium tetroxide for 5 min. and stained with Giemsa fluid, diluted 1:20 with distilled water.

Fig. 2. Gametogenesis in *Amoeba spumosa*; the arrow shows a gamete that is escaping

The size of the gametes ranges between 2.6μ, which is the diameter of a gamete escaping from the mother amoeba, and 11μ: it takes about a fortnight for the gametes to reach this size. The gametes about five days old measure 6.8μ and at this time they copulate. The copulating gametes have the same size; therefore they appear to be isogametes and the zygote, as soon as it is formed, shows bilateral symmetry. A systematic study to see whether there are phenomena of relative sexuality is in progress.

Larger gametes, more than 7μ in diameter, correspond to a senescent stage. These large gametes, which did not copulate and will never copulate, undergo a slow degeneration. These large flagellate forms are, in fact, less stainable and show such a delicate protoplasmic structure that even a dilute staining solution may dissolve them.

The diagram (Fig. 3) illustrates the increase of four different gamete cultures at the stage before copulation. After the discovery of this increase we tried to study it from a cytological point of view. An increase in the size of the vacuoles, which are

Fig. 3. Increase in diameter of the gametes of *Amoeba spumosa* after their release

placed at the gamete's anterior end, starts during the gamete growth. Some of these vacuoles contain small bodies intensely stained red by Giemsa fluid: they seem to be bacteria living in the culture medium. The conclusion, drawn from the study by the electron microscope¹, that a gamete ingests some bacteria and digests them in its vacuoles, is therefore confirmed. It seems, therefore, that gamete growth depends on true nutrition and not merely on an imbibition process by taking up water.

VIROLOGY

Concentration of Poliovirus by an Aqueous Polymer Two-Phase System

WITH the technique for polio vaccine production used at present, the end-point titres often are in the neighbourhood of 10^6 /ml., which is recommended as the lowest limit. Different methods have been tested to find a simple way for concentration of the virus. The physical and chemical methods proposed so far are rather complicated and give a comparatively low yield of virus¹. Variations in the technique for cultivation of the virus have also been suggested as a means of increasing the virus titres².

In the experiments to be described here, a physico-chemical method for separation and concentration of macromolecules was used³⁻⁵. The method is based on the almost completely one-sided distribution of macromolecules which may be obtained when these are distributed in an aqueous two-phase system containing two different polymers. For concentration purposes, a phase system is constructed in such a way that the phase in which the virus particles are collected has a small volume compared with the original virus suspension. The virus is partially separated from other cellular constituents since these are distributed in a different manner^{6,7,9}.

In the present experiments, sodium dextran sulphate (prepared from a dextran fraction with a limiting viscosity number of 70 ml./gm.; sulphur content, 17 per cent; Pharmacia, Uppsala, Sweden) and polyethylene glycol ('Carbowax 6000'; Carbide and Carbon Chemicals Co., New York) were used for concentrations of poliovirus. Experiments with the same system have recently been made on ECHO virus⁹. The results of the application of the system to poliovirus, however, are considered worth while reporting, with regard to the possible use in vaccine production.

The polymers were added to harvested tissue culture fluid from CHAT-infected monkey kidney cultures until the final concentration was 0.2 per cent (w/w) dextran sulphate and 6.45 per cent polyethylene glycol. The virus suspension had previously been clarified by centrifugation for 10 min. at 2,000 r.p.m. In addition, a 5 M sodium chloride solution was added until the salinity of the total mixture was 0.3 M. After careful mixing, the system was allowed to separate for 24-48 hr. at $+4^\circ\text{C}$. Samples were then withdrawn from the top and the bottom phase and from the layer between these two—the interface. The titrations of the virus were carried out in monkey kidney tissue culture tubes, and logarithmic end-point titres were calculated.

A typical experiment gave the results shown in Table 1.

Table 1

	Virus titre/ 0.1 ml.	Volume (ml.)	Total amount of virus (ID_{50})
Original material			
Bottom phase (phase rich in dextran sulphate)	6.5	100	3.2×10^9
Interface	8.4	1.2	3.0×10^9
Top phase (phase rich in polyethylene glycol)	7.7	—	—
	4.6	134	5.2×10^7

The bottom phase obtained represents about 1/100th of the total volume of the system. The virus, which accumulates in the bottom phase, is therefore concentrated 90-100 times. In controls, none of the polymers showed harmful effect on the virus. At the interface some proteins, probably cell debris, were precipitated. No change in the immunogenic capacity of the final preparation, measured in guinea pigs¹⁰, was found.

The bottom phase contains 17 per cent dextran sulphate and is rather viscous; therefore it would be inconvenient as a vaccine preparation. The following methods were tested to remove the dextran sulphate:

(1) Precipitation by adding either 0.69 ml. 3 M potassium chloride or 0.3 ml. 1 M barium chloride per gm. bottom phase. All the virus activity remained in solution.

(2) Addition of 5 M sodium chloride to the collected bottom phase until the concentration of the sodium chloride became 1 M. By this procedure a new phase system was obtained. The volumes of the phases and the distribution of the virus in this system are shown by the results of the experiment recorded in Table 2.

In this secondary system almost all the dextran sulphate is in the bottom phase. Because of the changed molarity, more than 99 per cent of the virus is accumulated in the top phase. This contains only

Table 2

	Volume (ml.)	Titres/0.1 ml.	Amount of virus (ID_{50})
Original virus suspension	200	7.1	2.6×10^{10}
Primary system : bottom phase	2.0	9.3	4.0×10^{10}
Secondary system : top phase	0.5	9.8	3.2×10^{10}
bottom phase	1.9	6.7	9.5×10^7

dextran sulphate of the order of 0.1 per cent and in addition about 1 per cent polyethylene glycol. These small amounts of dextran sulphate may be eliminated by the chemicals suggested in (1). Since the volume of the top phase is about one-fifth of the total volume of the secondary system, a further concentration of virus is obtained.

The procedures described with poliovirus in the system dextran sulphate-polyethylene glycol leads to purification and a 100-500 times concentration of the virus. The product shows an antigenic capacity, which corresponds to the infectious titre measured by the cytopathogenic effect in tissue culture. Residual concentration of polymers in the concentrate is of the order of 0.1-1 per cent.

SOIL SCIENCE

Diffusion of Ions in Soils

A KNOWLEDGE of the speeds at which ions diffuse in soils is of both basic and agronomic importance, but the development of accurate methods for the measurement of diffusion coefficients has received little attention. During an investigation of the factors controlling the rate of diffusion, the following method has been evolved.

The value of the coefficient of diffusion (D) from Fick's law can be obtained for the system shown in Fig. 1, where at the time when the two sections of soil are placed in contact the amount of the ion under investigation is equal in the two halves, but in one a proportion consists of a radioactive isotope. The quantity of material Q which is diffused across the boundary CD in time t can be calculated from the relationship:

$$\frac{Q}{Q_{\infty}} = 1 - \frac{8}{\pi^2} \left[e^{-At} + \frac{e^{-9At}}{9} + \frac{e^{-25At}}{25} + \text{etc.} \right] \quad (1)$$

where $A = \frac{D\pi^2}{4L^2}$, L is the distance represented by AC and Q_{∞} is the quantity which would cross the boundary in infinite time. When the value of $\frac{Q}{Q_{\infty}}$ is less than 0.5 this equation may be replaced by:

$$\frac{Q}{Q_{\infty}} = \frac{2}{L} \sqrt{\frac{Dt}{\pi}} \quad (2)$$

That either equation (1) or equation (2) may be employed according to the value of $\frac{Q}{Q_{\infty}}$ is illustrated

by results for comparable experiments on the diffusion of rubidium (rubidium-86) in a Greensand soil.

Using equation (1) for $\frac{Q}{Q_{\infty}} = 0.96$ a value of 6.19×10^{-8} cm.²/sec. was obtained for D , while the value from equation (2) when $\frac{Q}{Q_{\infty}} = 0.417$ was 6.13×10^{-8} .

By plotting graphically the theoretical relationship between $\frac{Q}{Q_{\infty}}$ and At of equation (1), a curve of the type shown in Fig. 2 is obtained. From this curve a value of A may readily be obtained given the experimental determination of $\frac{Q}{Q_{\infty}}$ for a known time t . D is then calculated from A . This simplified method has been found to give sufficient accuracy.

For experiments with soil, the conditions of the model shown in Fig. 1 are difficult to reproduce, since it is difficult to place two sections of soil in contact so that the boundary is sharp, and the subsequent separation and analysis are accurate. If the system is made so large that errors at the boundary are negligible, then experiments take an unduly long time to complete, for the root mean square displacement of the ions is proportional to $\sqrt{t}$. This problem of experimental procedure has been solved in the following way. It may be seen from Fig. 1 that

Fig. 1. Two layers of soil with an equivalent content of the ion under investigation are placed in contact and in one a proportion of the ions is present as the radioisotope. At the moment of contact the radioactive ions in section $ABDC$ are uniformly distributed and the height AB represents the value of the original concentration. As a result of the diffusion process radioactive material will move across the boundary CD into the section $CDFE$. As this process continues, the form of the distribution will change with time, as shown by the curves 1, 2 and 3. The line HJ represents the final distribution after an infinite time.

Fig. 2. The relationship of Q/Q_{∞} and At as calculated from equation (1)

immediately the ions cross CD , the concentration at this boundary falls to a value represented by DG ($= \frac{1}{2}AB$) and afterwards remains at this level. If a thin sheet of a permeable ion-exchange material containing the diffusing ions at a concentration in equilibrium with DG is inserted between the two sections, the rate and pattern of movement in the soil will be affected to a negligible extent, provided first that the rate of diffusion in the exchange material is fast enough relative to that in the soil, and secondly, that the exchange capacity of the material is considerably higher than that of the soil. It has been found that 'Permaplex' ion-exchange membrane is suitable for this purpose. Calculations for the system indicate that the maximum error introduced by the resin is equivalent to less than 1 per cent of the length of the soil sections (AC of Fig. 1).

The method of experimentation is as follows. Two disks of the ion-exchange membrane are shaken individually in identical solutions containing equal aliquots of a given soil, but in one solution a radioactive isotope of the ion under investigation is incorporated. After equilibration with the soil the two disks are removed and held in contact for about 24 hr. until the radioactive ions have become uniformly distributed as a result of diffusion. One disk is then used to separate the equilibrated radioactive and inactive layers of the selected soil in a small closed cylinder the diameter of which is the same as that of the disk, that is, 1 in. The other disk may be kept to check that the disk in the cylinder does not gain or lose radioactivity during the experiment. The two layers of soil are later removed after a known time and extracted so that the quantities of radioactive material diffusing from one layer to the other may be measured. The value of the diffusion coefficients can then be calculated.

Diffusion coefficients vary with concentration, but the use of radioactive tracers makes it possible to measure differential coefficients of diffusion at exact concentrations under conditions where the total concentration is constant throughout the system but where a gradient of radioactive ions exists. Moreover, the tracer method also eliminates the complexities associated with the displacement of other adsorbed cations.

Using this technique it is possible to work with layers of soil only 2.5 mm. thick. The results so far obtained indicate that the diffusion coefficient may be

as high as 1.2×10^{-7} cm.²/sec. (corresponding to a root mean square displacement of 1.4 mm. in a day). Detailed experiments on one Greensand soil have so far shown that the rate of diffusion is considerably affected by compaction, being maximal at about 1.5 gm./ml. The effects of both temperature and the concentration of the soil solution suggest that a considerable part of the movement takes place when the cations are held in the exchange complex.

The research is now being extended to cover diffusion of several cations and anions in a variety of soils, together with a further analysis of the effects of the water content of the soil, the concentration of the soil solution, and temperature.

We wish to acknowledge our indebtedness to the Agricultural Research Council for a grant in support of this investigation.

Aluminium Ions in Aluminium Hydroxide, Phosphate and Soil-Water Systems

In recent years attention has been given to the solubility of aluminium phosphates in soils. Of the synthetic preparations examined, variscite, $\text{Al}(\text{OH})_2\text{H}_2\text{PO}_4$, has been most extensively investigated and criteria for its existence in soils evaluated¹. It has been assumed that the solubility product of variscite can be determined from the activities of the ionic species in the expression $K_{sp} = (\text{Al}^{3+})(\text{OH}^-)^2 \cdot (\text{H}_2\text{PO}_4^-)$ and predictions of the phosphate content of soils have been made on this basis².

A recent investigation on the ionic species of aluminium in equilibrium with various forms of aluminium oxy-hydroxide and hydroxide has shown that for conditions usually found in soils, AlOH^{2+} , $\text{Al}(\text{OH})_2^+$ or less-highly charged forms such as $\text{Al}_3(\text{OH})_7^{2+}$ (strictly $[\text{Al}_3(\text{OH})_7]^{2+}$, where n is an integer, but we assume the monomer, although the dimer is perhaps preferable) may be present in appreciable amounts. This means that these species may also determine K_{sp} .

For pH less acid than 4 in the presence of newly formed aluminium hydroxide (commonly called amorphous) and in an unbuffered system of very low ionic strength, the curve obtained on plotting the negative logarithm of the number of moles of aluminium per litre of solution $[p\text{Al}_M]$ against the pH had a slope of 2, indicating that $[\text{AlOH}^{2+}][\text{OH}^-]^2 = \text{constant}$ (curve C in Fig. 1). This curve agrees with the other workers' results for solubility and hydrolysis. In the presence of buffers, when the system was required to adapt itself to a demand for hydrogen ions by the buffer, more hydrolysis occurred and a curve (D) was obtained with a slope 2/3, which means that $[\text{Al}_3(\text{OH})_7^{2+}][\text{OH}^-]^2 = \text{constant}$. When gibbsite was present, curve B resulted, which agrees with data in the literature on aged aluminium hydroxide. Experiments with diasporite showed that it was less soluble than the previous two forms and gave a curve (A) of slope 1 for pH less acid than 4.6, indicating that here $[\text{Al}(\text{OH})_2^+][\text{OH}^-] = \text{constant}$. Curve A also agreed with results from the literature for corundum and $\text{Al}(\text{OH})_3$.

Fig. 1. Relationships between the negative logarithm of the number of moles of aluminum per litre of solution and the pH. Curve A as found for diaspore (■) and predicted for corundum dissolving as $\text{Al}(\text{OH})_3^{+}$; curve B as found for gibbsite (□) and as predicted for aged aluminium hydroxide dissolving as $\text{Al}(\text{OH})_3^{2+}$; curve C as found for fresh aluminium hydroxide in buffered systems (see text). Data for variscite (x), variscite-kaolinite (▲) and phosphated and unphosphated sodium and aluminium kaolinites (△) and for three soils (○) on treatment with 0.01 M calcium chloride are also given. The dotted points falling in a group on the upper left of the figure are for soils treated with 0.001 M hydrochloric acid and 0.01 M calcium chloride.

It is of interest to superimpose on Fig. 1 results obtained by other workers for solutions in equilibrium with variscite, clays and soils.

The data for a variscite-kaolinite system³ (represented by a single point in Fig. 1 where equilibrium has been reached after 56 days), for variscite³ and for aluminium and sodium kaolinites phosphated and unphosphated⁴, fall largely between lines A and B. The data for soils presented in Fig. 1 are for 0.01 M calcium chloride extracts of Hagerstown s.l., Greenville f.s.l. and Mardin s.l. (refs. 1, 5) (no activity corrections have been applied). The phosphate found in these solutions does not influence the position of the points in any uniform manner, although the range of variation of phosphate is greater than a hundredfold. This indicates that in these systems the important relationship is between $p\text{Al}_M$ and pH (ref. 6). Not all soils would be expected to follow lines A and B. The data of earlier workers⁷ on more acid soils lie for the greater part against line C, showing that $\text{Al}(\text{OH})_3^{2+}$ was present and indicating that some Al^{3+} may be present under more acid conditions than pH 4.3. Again, the phosphate-level did not exert a systematic influence on the position of the points. These results show that the various aluminium hydroxides examined, amorphous, gibbsite and diaspore, may well represent stable phases in these soils. If variscite coexists as a discrete solid, its solubility does not appear to be fully exerted. On the other hand, it has long been advocated that the phosphate is bound to aluminium hydroxide to form a sorption compound.

The possible existence of variscite in some soils cannot, however, be discarded lightly, because soil-water systems have been observed to show reactions very similar to those of variscite, including the minimum phosphate solubility near pH 4 (ref. 8).

While the reactions giving rise to the solubility of variscite in more acid regions are reasonably clear, little is known of what occurs under more alkaline conditions. A possible reaction which would give rise to an increased solubility of variscite with increasing pH is:

This would give a slope of the pH and logarithm of the soluble phosphate curve which would be of the correct order for variscite and laboratory equilibria for a lateritic soil⁸. It would mean that the point of minimum solubility should be in the pH range 4.2–5.2 (that is, the intersection of curves B and D or C and D) as found in practice. If the kind of aluminium hydroxide present in a 'variscite' system is varied the value of the solubility product will vary so that care must be taken in extrapolating predictions from one situation to another even when it has been shown that the solubility of variscite is a controlling factor. It is clear that, for a detailed knowledge of reactions occurring in soil phosphate systems, it is necessary to study the ionic species present in the soil solution. The next step is to endeavour to determine which are the key reactions in the intricate interplay of processes taking place in the soil solution.

I hope to publish a full account of this work in due course.

ARCHAEOLOGY

Recent Discoveries at Olduvai Gorge

As a result of the discovery in 1959 of the skull of *Zinjanthropus boisei*¹, in association with an Oldowan living floor at site F.L.K. I Olduvai, funds for a much more extensive programme at the end of 1959 and during 1960 were generously made available by the Wenner Gren Foundation, the Wilkie Foundation and the National Geographic Society of Washington, to all of which I express my deep gratitude.

After some preliminary work in December 1959 and January 1960, major excavations were started at site F.L.K. I (where the skull came from) in the middle of February 1960. These excavations are progressing very satisfactorily. An extensive and rich living floor of approximately 1–2 in. in thickness has been uncovered. It rests on a bentonitic deep-water clay and is immediately overlain by a consolidated deposit of water-laid volcanic sand. This living floor lies some 20 ft. below the uppermost deposit of Bed I.

Neither the underlying clay nor the overlying consolidated volcanic sand contains any large bones, nor any coarse material of any kind, and every large object lying on the living floor must have been brought there. All the larger animal bones have been broken open to obtain the marrow; all jaws and skulls of animals are smashed. A high proportion of the bones represent immature animals. Many more stone tools of the Oldowan culture have also been found.

Our hope of obtaining the mandible which belongs to the original *Zinjanthropus* skull has not, so far, been realized, but we now have a nearly complete tibia and fibula (Fig. 1), as well as what is probably a small piece of the pelvic girdle, together with some additional teeth and parts of the skull of a second individual, all from this original site.

The quantity of stone tools and flakes now available from this living floor will make it possible to assess the components of an industry of the Oldowan culture in great detail.

In addition to the excavations at this main site, a second site has been located, not far away, at what appears to be a slightly lower level of Bed I. This site is called *F.L.K.N.N. I* and, so far, it has yielded an amazing wealth of fossils—but only a very few artefacts.

The hominid fossils from this second site include fragments of a skull and some teeth, two clavicles (Fig. 2), a large part of a left foot (Fig. 3), six finger bones and two ribs. The animal fossils consist of a remarkable assemblage of genera and species, many of them new to Olduvai, and some unquestionably new to science.

Perhaps the most remarkable object from this second site (*F.L.K.N.N. I*) is a genuine bone tool

Fig. 1. The tibia and fibula from site *F.L.K. I*

Fig. 2. One of the two clavicles from site *F.L.K.N.N.*

Fig. 3. Some of the bones of the left foot. The calcaneum is damaged

(Fig. 4). This would appear to be some sort of a 'lissor' for working leather. It postulates a more evolved way of life for the makers of the Oldowan culture than most of us would have expected.

Yet another site in Bed I (known as *F.L.K.N. I*) has been located during the past few weeks. This lies at a level some 20 ft. above the other two floors and immediately below the topmost deposit of Bed I. This third site consists of a very rich living floor with quantities of broken-up animal bones and many stone tools and flakes. Work on it has only just started.

Fig. 4. Bone tool from site *F.L.K.N.N. I*

Excavations have also been conducted at a site known as *F.L.K. II*, which is stratigraphically well above the main *F.L.K. I* site, and this, as was expected, has yielded a fauna comparable to that of Olduvai sites *B.K. II* and *S.H.K. II*. The fauna is in direct association with an assemblage of artefacts of Stage 3 of the East African Chellean sequence.

The discovery of parts of hand and foot are of very special importance, for hitherto we have had no knowledge of these parts of the skeleton in early hominids.

This year's work has very strongly confirmed the statement which I made last year that Bed I is very distinct (both from the point of view of its fossil fauna and its culture) from Beds II, III, IV. Bed I is of Lower Pleistocene, or Villafranchian age; whereas Beds II, III and IV belong to the Middle Pleistocene.

As a result of the work carried out so far this year, the National Geographic Society has kindly made available a further grant to continue work for four or five more months.

L. S. B. LEAKEY

MISCELLANY

"Education of Scientists"

In his account of the British Association meeting on the education of scientists in *Nature*, October 22, p. 270, Prof. M. W. Thring reports that students who have obtained a General Certificate of Education examination in six subjects, of which three are at the Advanced Level, have reached the minimum requirements for entry to a university. These attainments are, in fact, much higher than are specified by the majority of British universities for entrance purposes.

In my own lecture, I was commenting on the high calibre of students joining the Diploma in Technology courses and expressing my satisfaction that, of the 700 students already accepted for these courses at the Northampton College of Advanced Technology, London, more than 300 had passed in three subjects at the Advanced Level in addition to the Ordinary Level requirements.

One other matter in the report needs clarification. In setting up the diploma in technology, the National Council for Technological Awards had clearly in mind that students who obtained first-class honours should be every bit as good as the first-class honours university graduate, and there is every reason to believe that these aims are being attained. The recommendation of the Committee of Vice-Chancellors and Principals to the Universities, that holders of the diploma in technology should be considered on the same footing as university graduates for registration for higher degrees, was an acceptance of this belief, and it is good to know that the recommendations have already been put into effect. In fact, one young man whose qualification is a diploma in technology has joined the academic staff of a provincial university.

JAMES S. TAIT

Northampton College of Advanced Technology,
St. John Street, London, E.C.1.

Cost of Scientific Periodical Publications

I REFER to the figures showing the cost of scientific journals which have been given and discussed in recent issues of *Nature*. The figures quoted by Mr. K. W. Humphreys and Mr. H. D. Barry¹ give the comparable costs per page to libraries for various journals. (Incidentally, the cost of the *Biochemical Journal* is £4 per volume of approximately 620 pages, that is, 1.5d. per page, not 0.75d. as quoted.)

Captain Maxwell's table², however, compares the price charged to libraries for the *Journal of the Chemical Society* and some other journals with the price charged to individuals for the publications of Pergamon Press. Since fellowship of the Chemical Society is open to all approved persons throughout the world interested in the science, and one of the Society's main purposes is to disseminate chemical knowledge as widely and as cheaply as possible among scientists, it is proper to compare the price to Fellows with that of Pergamon journals to individuals. For the *Journal of the Chemical Society* the Fellows' price is approximately 0.5d. per page against a price to libraries of 1.0d. per page.

Captain Maxwell also states that a journal which has the backing of a scientific society has the advantage of a guaranteed circulation to its members, and, in most cases, a subsidy. These statements are incorrect if intended to apply to the Chemical Society, the only British publishing society mentioned in his table. The *Journal* is available only to those Fellows who choose to pay for it, and at the present time only some 16 per cent of Fellows exercise this option. Moreover, the Society does not receive any subsidy or outside grant for its publications, which are currently produced at a modest profit. I submit, however, that the prices quoted by your contributors show that this profit is not achieved by means of an unduly high price to libraries.

M. W. PERRIN

The Chemical Society,
Burlington House, W.1.

¹ *Nature*, **186**, 124 (1960).

² *Nature*, **187**, 1052 (1960).

CAPT. MAXWELL'S reply¹ to the paragraph concerning publication costs² is disingenuous; to show how cheap his publications are he compares his reduced price to private individuals with the top price of others to corporate subscribers. It is necessary in a fair comparison to compare 'like things with like'. Thus if, for example, *Tetrahedron* to the private individual costs 0.7d. per page, *Chemical Abstracts* to the private member subscriber costs 0.15d. per page, which brings our journal to the top of the list at a price and value which is second to none.

To say that journals backed by scientific societies have guaranteed circulation is unrealistic in most cases; it certainly is not true with *Chemical Abstracts*. Member subscribers to *Chemical Abstracts* are subsidized in an effort "to ensure maximum dissemination", but *Chemical Abstracts* has been on a self-supporting basis since 1956.

FORTHCOMING EVENTS

Monday, December 19

INSTITUTION OF MECHANICAL ENGINEERS, STEAM GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Safety on Construction Sites".

Tuesday, December 20

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENT AND CONTROL SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Digital Transducers", opened by Mr. L. Airey.

Wednesday, December 21

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS AND COMMUNICATION SECTION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. L. J. Ward: "Microministrization".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Discussion on "Practical Problems in Corrosion".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

ASSISTANT (graduate in mathematics, mathematical statistics or statistics, and preferably experience with punched cards and electronic computers) IN RESEARCH IN THE DEPARTMENT OF HUMAN ECOLOGY, to engage in the planning and the analysis of medical research projects—The Secretary of the Faculty Board of Medicine, The Medical School, The University, Tennis Court Road, Cambridge (December 31).

JUNIOR ASSISTANT LIBRARIAN (university graduate, preferably with some experience and/or professional qualifications in classification and cataloguing)—The Librarian, University College of North Staffordshire, Keele, Staffs (December 31).

LECTURER (with a degree in bacteriology or equivalent qualification) IN BACTERIOLOGY—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow, C.2 (December 31).

POSTDOCTORAL RESEARCH FELLOW IN PHYSICAL CHEMISTRY, to study the properties of solids by mass spectrometry—The Registrar, The University, Edgbaston, Birmingham 15 (December 31).

SENIOR LECTURER IN ORGANIC CHEMISTRY; and a LECTURER IN ZOOLOGY, WITH SOME PHYSIOLOGY—The Registrar, Hatfield Technical College, Hatfield, Herts (December 31).

COMPUTATIONAL ASSISTANT (with a degree in mathematics or engineering or similar qualification, and preferably experience of the use of an electronic computer) IN THE DEPARTMENT OF MECHANICAL ENGINEERING, to use the university digital computer for work concerning the lubrication research which is going on within the Department—The Registrar, The University, Leeds 2 (January 6).

LECTURER (with qualifications in any of the branches of zoology, and preferably an interest in physiology, genetics or some other branch of experimental zoology) IN ZOOLOGY at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 6).

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (honours graduate in biochemistry and/or physiology, with appropriate research experience), to undertake research on hill sheep nutrition—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (January 7).

CHADWICK CHAIR OF CIVIL ENGINEERING tenable at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (January 9).

FORESTERS (recently qualified university forestry graduates) in the New Zealand Forestry Service—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. B.11/9/8 (January 9).

HORTICULTURAL ADVISORY OFFICERS (with a degree in horticulture, preferably with practical experience in the production of horticultural crops, and in field advisory and experimental work) in the Agriculture Department, New Zealand, to advise growers on the production of horticultural crops, chiefly fruit and vegetables, undertake field experiments, and conduct surveys and special investigations—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. B.11/2/28 and Vacancy No. 3474 (January 9).

INSPECTORS OF EXPLOSIVES (2) (men or women at least 30 on November 1, 1960, with a degree (preferably first- or second-class) in chemistry or chemical technology, or equivalent qualification) with the Home Office, for duties involving travel to all parts of the country, and include advising on safety precautions for the manufacture, storage and conveyance of explosives; inspecting premises licensed for manufacture and storage; and advising on safety precautions for the storage and conveyance of petroleum and other dangerous substances—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting 8/5284/61 (January 10).

CHAIR OF CIVIL ENGINEERING—The Registrar, University College, Singleton Park, Swansea (January 14).

FISHERY INVESTIGATING OFFICERS (male, physically fit, with an honours degree in zoology, and prepared to spend considerable time in the field) in the Marine Department, New Zealand, to undertake local investigations and advise on biological aspects of freshwater fisheries management and development problems in all parts of New Zealand, with headquarters in Wellington—The High Commissioner for New Zealand, 415 Strand, London, W.C.2, quoting Ref. B.11/15/6 and Vacancy No. 3271 (January 16).

SOIL SURVEYORS (2) (graduates in botany, chemistry, geography, geology or agriculture and preferably with previous experience in soil survey, particularly in the tropics) in the Regional Research Centre for the West Indies, Faculty of Agriculture, University College of the

West Indies, Trinidad—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 20).

LECTURER (part time), to investigate respiratory functions in childhood—The Secretary, Institute of Child Health (University of London), Great Ormond Street, London, W.C.1 (January 21).

ASSOCIATE PROFESSOR OF MEDICAL BIOCHEMISTRY IN THE DEPARTMENTS OF MEDICINE AND BIOCHEMISTRY, University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 23).

CHAIR OF PARASITOLOGY in the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 31).

LECTURER or ASSISTANT LECTURER IN ELECTRICAL ENGINEERING—The Registrar, The University, Southampton (January 31).

SENIOR LECTURER IN CIVIL ENGINEERING (STRUCTURES) at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 31).

EXPERIMENTAL OFFICERS (preferably with a pass degree or H.N.C., and a knowledge of electrical and electronic methods of measuring displacement, velocity, acceleration, strain and temperature under vibration conditions and experience in the design of electronic circuitry would be an advantage) to set up and operate instrumentation for an interesting programme of environmental testing. Duties will include the design of special electronic instruments to meet particular requirements—The Senior Recruitment Officer, U.K.A.E.A., A.W.R.E., Aldermaston, Berks, quoting Ref. A.2684/84.

HEAD (man or woman, with a good honours degree and experience) OF THE MATHEMATICS DEPARTMENT—The Headmistress, Queen Anne's School, Caversham, Reading.

NATIONAL RESEARCH COUNCIL AND OTHER POSTDOCTORAL FELLOWSHIPS IN THE DEPARTMENT OF PHYSICS—Prof. H. E. Duckworth, Chairman, Department of Physics, McMaster University, Hamilton, Ontario, Canada.

PHYSIOLOGIST or ZOOLOGIST (with a good degree in physiology or zoology, preferably with Ph.D., and interests and experience in the field of mammalian reproduction) in a small unit investigating the biochemical and physiological properties of cervical secretions, with particular reference to fertility—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks, quoting Ref. 60/17.

READER (able to show evidence of research ability in the academic and industrial fields, and preferably with experience in the food industry) IN FOOD PROCESSING AND FOOD ENGINEERING—The Principal, National College of Food Technology, St George's Avenue, Weybridge, Surrey.

RESEARCH ASSISTANT (preferably with an honours degree in physical and inorganic chemistry) IN THE DEPARTMENT OF MINERALOGY AND PETROLOGY, for a programme of research concerning fundamental solid-state problems in the field of cement chemistry—Dr. J. D. C. McConnell, Department of Mineralogy and Petrology, Downing Place, Cambridge.

RESEARCH ENGINEER (with an honours degree in chemical engineering and proved research ability) IN THE DEPARTMENT OF CHEMICAL ENGINEERING, to work under Prof. Edgeworth Johnstone on the dimensional scaling-up of a particular type of process plant—The Registrar, The University, Nottingham.

SENIOR TECHNICIAN II (with special experience in bacteriology) to take charge of a laboratory—The Secretary, Forest Group Hospital Management Committee, Langthorne Road, Leytonstone, London, E.11.

INDUSTRIAL RESEARCH AND DEVELOPMENT

PUBLISHED BY THE INSTITUTION OF GAS ENGINEERS

IN the Sir David Russell Memorial Lecture delivered last March on the perils of leadership in science, Sir Lindor Brown said there are three major decisions of strategy to take in scientific work: what to start, when to stop, and where to go, in that rather peculiar order. Although Sir Harold Hartley's address* on the choice of subjects for research and development at the autumn research meeting of the Institution of Gas Engineers in November was concerned primarily with technology, his address recalled a good deal that Sir Lindor Brown said, as did indeed the debate opened by Lord Shackleton in the House of Lords on November 9 on the report of the Advisory Council on Scientific Policy. Lord Hailsham's important speech in that debate in particular indicated how largely the right balance of effort in the technological, as in the scientific, fields depends on wise decisions of exactly the type that Sir Lindor Brown emphasized. The prime requisite is always sound judgment.

Sir Harold Hartley, after quoting Prof. J. Jewkes's aphorism that science is directed towards understanding and technology towards use, and admitting that the economic aspects of research and development must always be governing criteria of policy, emphasized that the ultimate decision is always a matter of such judgment trained by experience. Moreover, like Lord Stamp, Sir Harold Hartley is well aware of the importance of suiting the tool to the job; Lord Stamp's observation that, while in writing a paper for the Royal Society 100 per cent accuracy is the objective, in industrial research a 60 per cent accuracy is a good achievement, is in line with Prof. T. L. Cottrell's recent criticism of the graduate's failure to apply theory or to approach a problem critically and consider the purpose to be served before choosing the means. Clearly what Sir Harold Hartley has in mind is the ability to seize an opportunity, and to make sound decisions as to what real openings may be offered by some interruption of a research programme through the demands of what he describes as first aid or an emergency call for immediate help.

Sir Harold is obviously prepared to accept a certain amount of such work as a legitimate function for a research department, provided that a careful watch is kept for such opportunities of new developments. Apart from this, it may lead to the acquisition of experience on which sound judgment can be based; this is not less true of work directed at the improvement of existing practices and products. Here he recognizes that the selection of research projects and the guidance of their progress are matters of national importance, and that it is not easy to determine the division of effort between the development of existing practices and exploring the possibilities of entirely

new departures. One function of research in regard to the former is the provision of accurate and simple means for assessing efficiency; but this can tell us nothing about entering entirely new fields. On the other hand, the considerations and criteria that could be applied in assigning priorities to possible research projects, which Sir Harold described in this section of his paper, seem to be responsible for the continued demand manifested both in the House of Lords and in the House of Commons for the release of more information on such topics as the reports on ship-building research and on the machine-tool industry in Britain. It should also be added that in his reference to operational research into maintenance costs and research into instrumentation and automatic control, Sir Harold touched on a field which it is recognized offers increasing opportunities for co-operation between firms and groups of firms, both nationally and on an international scale.

In discussing his third category of research and development projects, namely, those aimed at the invention and development of new techniques, new materials and new appliances, Sir Harold Hartley relies rather too closely on Prof. J. Jewkes's study in "The Sources of Invention", and does little to clarify the distinction between research and invention or the factors that contribute to inventiveness, or even the criteria that may guide the choice of projects for research and development. Indeed, he accepts it as axiomatic that the bulk of the work of most industrial research laboratories will be concerned with what he describes as first aid, and with the improvement and development of existing processes in the light of advances in scientific knowledge. The choice of the latter projects must rest on cost analysis, on market research, and judgment of their scientific and engineering possibilities, though to suggest that they must also rest on the research effort available is to contradict a remark Sir Harold made in opening his address: there is surely a time at which a project calls for an expansion in research staff to seize an opportunity. That at least is obvious from some of the case-histories of Prof. Jewkes which Sir Harold quotes.

Sir Harold's argument here seems essentially to stress the importance of such an inquiry as that undertaken by the Advisory Council on Scientific Policy at the request of the Minister for Science; but he rightly emphasizes the need to adjust a research programme from time to time in accordance with its progress and other circumstances, and the importance in the direction and administration of research of an intimate day-to-day contact with the individuals concerned so as to avoid frustration or the destruction of confidence. He also makes one important constructive suggestion. The most successful system he has seen involved detaching a group of able people

* Institution of Gas Engineers. Publication No. 578: The Choice of Subjects for Research and Development. By Sir Harold Hartley. Pp. 9. (London: Institution of Gas Engineers, 1960.)

from all responsibility for specific projects, so that they could follow the progress of the different projects and keep in close touch with both the makers and the users of the products of the laboratory. The group was thus in a position to adjust the research programme to meet changing circumstances, and it was on its advice that projects were strengthened if they showed promise and were needed, or slowed down, or stopped. Sir Harold recognizes that such a system requires delicate handling, but he said that it had worked well and prevented projects being continued long after they were likely to pay a dividend. It does not, however, appear to be a system that is easily applied to fundamental scientific research; but it is easily recognized as the embryo of the Advisory Council on Scientific Policy, as distinct from the research councils themselves. Lord Shackleton, who opened the debate in the House of Lords on November 9, appeared to recognize this, though he was not altogether willing to accept the division of function and responsibility between a research council and the Advisory Council for Scientific Policy. He seemed to lean too readily to the view that massive support of research is all that is required and to ignore the demands which the selection of projects makes for judgment. It is true that in discussing the magnitude of the research and development effort in Britain he recognized the need for further investigation, and particularly into comparative figures for expenditure in terms of the gross national product, but he was concerned as to whether the right balance was being maintained between research and development.

That balance was not really considered in the Advisory Council's recent report, which Lord Shackleton was discussing, but he did not suggest that the balance was necessarily wrong. He admitted that the distinction is difficult to draw in practice, and it could well be maintained that any survey of the scientific effort in Britain as a whole, such as the Advisory Council initiated, could not fail to bring to light any weaknesses, in either pure or applied science; indeed, the recent report directs attention to gaps quite impartially in the scientific and the technological field. Some of those gaps, as Lord Shackleton himself acknowledged, have been emphasized by Lord Hailsham, and two in particular received some emphasis in the debate. Both these were noted by Lord Shackleton, and Lord Hailsham, who followed him, referred to them in some detail. He began by stressing the importance which he and the Council attach to the reports of the Economic Section of the Council for Scientific and Industrial Research into the machine tools industry and into the shipbuilding industry. The purpose of these reports, which were concerned solely with the scientific and research aspects of these industries, was to keep the Advisory Council informed on the economic aspects of their scientific research and on their particular research programmes, so as to enable the Council to advise industry on what they may regard as their research requirements. In other words, the Economic Section is in large measure

assisting the Advisory Council to fulfil one of the essential functions to which Sir Harold Hartley directed attention in his address to the Institution of Gas Engineers.

Lord Hailsham said that the report on the machine tools industry was compiled with the full co-operation of the industry and contained so much confidential information from individual firms that an undertaking had to be given that it would not be published without the consent of the industry itself. He believes that the report has already yielded important results. For example, it appeared that the pattern for training engineers in universities and colleges is not well suited to the needs of the machine tool industry, and in consequence of the report new courses are likely to be available. Also, it had established forcibly the need for a research association and one is already being formed. The need for development on certain lines had also been brought to light, and Lord Hailsham also referred to a forthcoming report from a committee under the chairmanship of Sir Stewart Mitchell appointed to consider Prof. Seymour Melman's report on the Western European machine tool industry presented to the European Productivity Agency last year.

This report was published on November 10, and afterwards the Department of Scientific and Industrial Research and the Machine Tools Trades Association issued a statement giving details of what is being done by way of schools of research, higher training in machine tool technology, scholarships and special courses, to meet the challenge to the British industry. Subsequent speakers in the debate again pressed Lord Hailsham on the publication of these two reports; but although he indicated that he had always favoured publication of such documents, he firmly defended the decision not to publish on the ground that a promise had been given in good faith that private information should be kept private. Nevertheless, it was clear that Lord Hailsham was much less happy about the report on the shipbuilding industry, and did not exclude the possibility of publication of that report or some modified version of it, or some programme of research which would embody part of the report. He stated originally that the information was not obtained on quite the same confidential basis as that in the report on the machine tool industry, and he did not regard the Department of Scientific and Industrial Research as having given an undertaking that the information should not be published. The decision whether or not the report should be published must rest with the Council for Scientific and Industrial Research; all that he urged was that the confidential discussions on which he was engaged with the industry should not be prejudiced by publication. On December 1, Sir David Eccles, as representing the Minister for Science, stated in the House of Commons that the industry and the Department had that morning agreed on publication as early as possible.

Two other comments made by Lord Shackleton drew important statements from the Minister for

Science. Lord Shackleton referred to the organization of Government research and the work of the Zuckerman Committee, and in reply Lord Hailsham outlined very clearly his conception of his own responsibilities. He proposed to use the Advisory Council on Scientific Policy as was indicated in its current annual report; but while the Government is responsible for seeing that gaps in our scientific activities are filled and the work is done, the responsibility for doing the work rests elsewhere—with the Research Councils, Government departments, the universities and industry. He is considering with the officers of the Royal Society how an even closer liaison could be achieved between that Society and the various bodies for which he is responsible.

In reply to Lord Shackleton's comment that some of the recommendations in the Advisory Council's report are too general, Lord Hailsham suggested that his function was to some extent discharged, in any event in the first degree, when he caused these questions to be asked; and that the right inference to be drawn was that the proposals are actively under discussion in independent fields as a result of the inquiry. Specifically, he agreed that the arrangement of the rapidly increasing work within the scope of the Research Councils requires further consideration; but as regards Lord Shackleton's request that he should entrust the responsibility for natural resources to the Nature Conservancy, he said that the Advisory Council on Scientific Policy would probably be asked to consider in the near future the detailed pattern of our effort in regard to natural resources.

On receiving the recent report, Lord Hailsham said he had directed the attention of the various responsible bodies to findings which he thought particularly concerned them. He was confident that the universities and the University Grants Committee would take the report into account, and though he fully recognized the force of the objection to earmarked grants, Lord Hailsham indicated that he would not hesitate to deal with the difficulty if need arose. He is particularly concerned at present, he said, both with the shortage of qualified engineers and with the insufficiency of engineering research, both in the universities and in industry. Both these factors are major weaknesses in Britain at present, and will not be removed until this field attracts a due proportion of the best intellects in the country.

Here Lord Hailsham suggested a decisive factor is the status which engineering enjoys in the universities, and this is a matter which only the universities can remedy. Lord Hailsham did hesitate to proclaim his own view that engineering should enjoy a far higher status in the universities than it has hitherto been allowed to do, and his profound respect for university autonomy should not be construed as inhibiting action if due regard is not paid to Britain's interests. Obviously, he prefers to work through the accepted channels, but the whole tenor of his speech implied readiness for resolute and even drastic action here and elsewhere if the need were established.

One other topic on which Lord Hailsham touched is the matter of development contracts. In 1952 the Advisory Council on Scientific Policy recommended that the use of development contracts in civil industry should be urgently explored, and afterwards the function of the National Research Development Corporation was extended to cover the promotion of research likely to lead to some important invention. The Department of Scientific and Industrial Research has been authorized to act as focus for the idea of civil development contracts; but so far results, apart from the activities of the Atomic Energy Authority and the National Research Development Corporation, have been meagre.

The Advisory Council takes the view that the problem of the development contract is not insoluble, though it is very difficult when Government is not the direct customer and has not laid down in detail the specifications and objectives; but a solution should substantially improve the development of the results of scientific research. It is not, however, in the Council's view, a problem to be solved by centralized action alone, but one in which industry must take a leading part. Essentially it is a matter of research-mindedness and a tradition of using the results of scientific and technological advance.

Lord Hailsham expressed the hope that this situation would soon be altered. He referred to proposals for development contracts in the field of machine tools likely to be put forward through the National Research Development Corporation or the Department of Scientific and Industrial Research, and to proposals under discussion for computers. It is possible that a new technique may be developed; but if this does not happen, it is clear that Lord Hailsham is prepared to examine the whole problem afresh, and in replying on the whole debate he made pointed and reassuring reference to the place of the research associations.

Neither the Advisory Council nor the Minister for Science is under any illusion that support of a research association is any substitute for research-mindedness and an active research policy within an individual firm; but both his speeches in this debate indicated that the Minister for Science, like the Advisory Council, has a firm grasp of essentials and of the conditions in which creative activity is most fruitful. Lord Hailsham revealed himself as determined to stimulate those conditions; but equally he was resolute to avoid generating unnecessary opposition or causing friction which might waste effort or defeat the objective. His final remarks that these matters should be kept clear of party politics so far as possible deserves to be widely noted. Emphatically, Lord Hailsham is right to hold that the relation between science and Government and between science and industry must be appropriate to the type of industrial and social organization a country possesses. All that should be added is that those relations should change as the organization may change, and without undue time lag. The provision of a Parliamentary Secretary to the Minister should assist the Minister for Science to pursue his inquiries into these and other matters

more readily and in greater detail. No scientist or technologist could well ask of a Minister for Science a more forward-looking mind than Lord Hailsham revealed in the debate, or clearer indication of readiness to act where necessary, while respecting the practices and traditions which have proved their value in scientific and academic work. He obviously looks to the research associations to play an important educational function in industry apart from any actual contribution to research, and the debate should dispose of any uneasiness as to the future of the research associations as a whole. Specifically, in reference to an instance mentioned by Lord Pethick-Lawrence, of a scientist who had left Britain for America because he was unable to obtain the equipment he needed here, Lord Hailsham undertook to examine any similar instance in which some particular aspect of science was not properly cared for by the provision of apparatus if the matter were brought to his notice. The keen awareness of the importance of scientific and technical education at all levels, and perhaps especially of that designed to provide the supporting technicians needed in the universities, as well as in industry and Government departments and institutions, was a most encouraging feature of a notable debate.

THE NEWER COSMOLOGY

The Nature of the Universe

By Prof. Fred Hoyle. New and extensively revised edition. Pp. vii+103+6 plates. (Oxford: Basil Blackwell, 1960.) 8s. 6d. net.

THIS is a revised edition of the well-known book of some ten years ago in which Prof. Hoyle recorded his very popular broadcast talks on what he described as "The New Cosmology". The order of presentation and general style are unchanged, but there are, of course, revisions of certain details. Chief interest, however, will centre on the substantial changes, and these are considerable.

The estimated density of interstellar matter has been reduced a thousandfold, thus annihilating important effects formerly ascribed to the 'tunneling' of stars through this medium. The number of planetary systems in a galaxy is now at least 1,000 and perhaps 100,000 times greater than before, while the age of our Galaxy, previously given as "quite definite and precise" is now increased fourfold and has become "reasonably definite and precise".

The greatest change, however, concerns the origin of the planets. In the earlier book it was shown that the idea that these originated from solar material "must be wrong", "hopelessly wrong", and that the planets "must have" originated in the explosion of a companion of the Sun. Now, however, it appears that the planets did originate from solar material, the companion having been non-existent. "There is no idle speculation here." Prof. Hoyle's faith that the cosmology of 500 years hence will appreciably resemble the particular cosmology of to-day which he now favours remains unshaken.

It is very remarkable that such fertile imagination and mathematical skill can accompany such credulity and lack of critical power in one person. The

general reader may decide what weight to attach to the astronomical conjectures from the "personal view" at the end concerning "continued existence after death", for here he is not menaced by the fear of incommunicable mathematics in the background which elsewhere confounds his judgment. "My own answer would be that mind is an intricate organization of matter. In so far as the organization can be remembered and reproduced there is no such thing as death. If ordinary atoms of carbon, oxygen, hydrogen, nitrogen, etc., could be fitted together into exactly the structural organization of Homer, or of Titus Oates, then these individuals would come alive again exactly as they were originally. The whole issue therefore turns on whether our particular organization is remembered in some fashion. If it is, there is no death. If it is not, there is complete oblivion."

Suppose Prof. Hoyle were regrettably to die tomorrow, and someone fitted the atoms into the necessary structure: which view of the origin of planets would the resurrected mind, "as it was originally", take? If the structure changes from moment to moment while we live, to take account of growing experience, is it not strange that it never by accident gets shaken into a configuration that knows the future, and that so many otherwise quite diverse organizations all happen to be aware of the Suez crisis, say—now that it has occurred, of course? But perhaps, after all, our knowledge of these matters, as of some others, is not yet quite definite and precise.

HERBERT DINGLE

SPACE RESEARCH

The Exploration of Space

A Symposium on Space Physics, April 29–30, 1959. Edited by Robert Jastrow. (Sponsored by the National Academy of Sciences, the National Aeronautics and Space Administration, and the American Physical Society.) Pp. v+160. (New York and London: The Macmillan Company, New York, 1960.) 5.50 dollars; 38s. 6d.

THIS book is the record of the papers presented at the symposium on "Space Physics" held at Washington during April 1959, and of the 'round-table discussions' which concluded each session. The first three papers show how much has still to be learnt about interplanetary space, or the 'Sun's outer atmosphere' as it is now sometimes called. F. L. Whipple surveys our present knowledge of solid particles in the solar system, remarking that "the general subject of meteoritics is in a sorry plight". T. Gold deals with the ionized particles and magnetic fields, and stresses the importance of electromagnetic effects. E. Parker, looking at the same region with a different bias, emphasizes the hydrodynamic expansion of the solar corona, as it streams into space at speeds of around 500 km./sec. Next, the radiation zones are described by their discoverer, J. A. Van Allen, and the *Argus* experiment by its proposer, N. C. Christofilos. H. E. Newell reviews the United States plans for future space-vehicles, G. de Vaucouleurs summarizes what is known about Mars and Venus, and G. P. Kuiper discusses the Moon, contending that the craters are caused both by volcanic action and by meteoritic impacts. H. C. Urey, in a paper entitled "Primary and Secondary Objects", suggests that

stony meteorites originated in a primary object of roughly lunar size formed about 4,000 million years ago. There are two contributions concerned mainly with space-research techniques: H. Friedman on the rocket astronomy he has done so much to promote, and L. Goldberg on astronomy from satellites. Finally, J. W. Townsend outlines a programme for future space research, and R. Jastrow describes the Earth's outer atmosphere.

The book can be thoroughly recommended, and fully justifies the publishers' claim that it is a "comprehensive survey of the most recent developments in space science", though the developments are now not quite so recent as they were, since the increased pace of scientific progress has not been matched by any corresponding acceleration in printing, proof-reading—or reviewing. All but one of the papers given at the symposium were first printed in the November 1959 issue of the *Journal of Geophysical Research*, and the book is a faithful reproduction of the pages from the *Journal*, including all the misprints. The book illustrates a growing and deplorable tendency to reprint unchanged, in book form, scientific articles which are known to have misprints. If publishers wish to adopt this practice for economy, they should surely include a list of errata: for this book, such a list could well be headed by the value for the age of the Moon on page 143, which is in error by a factor of 10^{18} .

D. G. KING-HELE

INVARIANCE PROPERTIES OF PARTICLES AND FIELDS

Theory of Elementary Particles

By Paul Roman. (Series in Physics.) Pp. xii+575. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1960.) 100s.

THE progress that has been made in establishing a basic theory of the elementary particles and their interactions has depended to a large extent on the use of invariance properties under transformations. These range from the obvious Lorentz transformations to rotations and reflexions in isobaric space. They give rise to conservation laws, selection rules and relationships between reactions, all of which can be tested by experiment. Their deduction does not necessitate the solution of the field equations, which has so far not proved to be generally possible for the strong interactions. For the weak interactions almost complete understanding has been achieved as a result of the comparatively recent discovery of the non-conservation of P and C .

Dr. Roman's book is particularly concerned with the invariance properties and their influence on the structure of the quantum field theory used to describe the elementary particles and their interactions. The treatment is outstandingly good. It is inevitably mathematical and requires an effort on the part of the reader (particularly the experimental variety), as is recognized by the author in his preface. He has most successfully sugared the pill by setting out the mathematics in considerable detail and carefully discussing its implications and limitations. The experimental implications are kept constantly in view and it is made clear how experimental results have determined the structure of the theory at every stage.

The first 100 pages are devoted to the theory of the four-dimensional orthogonal group and its representations. In the next 114 pages the quantum field theory is developed, starting with a classical treatment of the field equations to establish their form for the different fields. Quantization of the fields is then introduced, leading to the commutation rules and the use of creation and annihilation operators. The remainder of the book is devoted to the invariance properties. In particular, P , C , T transformations and the relation between them are considered in detail and a section is devoted to the effects of the non-conservation of P and C in weak interactions. Transformations in isobaric space are then introduced, leading to the Gell-Mann Nishijima classification of the elementary particles. There are interesting discussions of the $|\Delta t| = \frac{1}{2}$ selection rule and of the properties of neutral K mesons. Finally, more complete mathematical models of the elementary particles are considered, including the Prentki-d'Espagnat theory of isospace. It should perhaps be mentioned that no attempt is made to include the methods (such as dispersion relations) that are being tried for dealing with the strong interactions.

This book can be recommended unhesitatingly to those who wish to become familiar with the basic theory of the elementary particles and their interactions. It will also be a vital source of reference for those who are only intermittently concerned with the basic aspects of the theory.

A. ASHMORE

CHEMICALS AND INSECTS

Methods of Testing Chemicals on Insects, Vol. 2. Edited by Harold H. Shepard. Pp. iii+248. (Minneapolis, Minn.: Burgess Publishing Company; London: Mayflower Publishing Co., Ltd., 1960.) 40s.

THIS volume is the second in a series projected by the former Chemical-Biological Co-ordination Center, having as its object the publication of "a manual of test methods dealing with the effects of chemicals on insects".

The first volume has already been reviewed in *Nature* (183, 352; 1959). The second volume begins with a group of three papers: "Pre-test Conditions which affect Insect Reaction to Insecticides", "Factors affecting Insects during Exposure to Insecticides", and "Post-exposure Conditions and Determination of End Point". This division looks orderly on paper, but it is difficult to maintain, and a single chapter would probably have been preferable. Much of the second chapter would be more correctly entitled "Factors affecting Insecticides during the Exposure of Insects"—which is quite a different subject.

The remaining chapters deal with testing methods for insecticides used for specific purposes. Chapter 4, "Exposure to Treated Food Medium", and Chapter 5, "Screening Space Sprays against Flies and Cockroaches", give good straightforward outlines of the methods used, but some comments on the fundamental factors concerned would have assisted the intelligent use of these methods. Chapter 6 deals with "Soil Insecticides". Chapter 7, "Testing Resistance of Chemically Treated Textiles", unlike Chapter 5, gives full details for carrying out the tests, and it may be said again that it seems regrettable that the

various contributions are not standardized in this respect. Chapter 8, "Screening Chemical Repellents", describes various methods, and instructively relates the fundamentals of the subject to the testing procedure. Chapter 9 deals with "Insect Proofing of Food Packing Materials". Chapter 10, "Screening Chemical Attractants", gives a rather unorganized account of this difficult subject. It includes a method for assessing 'contact attractance' which is out of place, and much material about the use of attractants in conjunction with insecticides which has no relevance to screening.

Chapter 11, "Testing Acaricides", is one of the best in the book, and supplies the information that anyone embarking on this work would require. Chapter 12, a short one, entitled "Animal Sprays, Dusts, Dips and Dressings", gives an account of field test methods. Chapter 13, "Techniques for the Evaluation of Systemic Insecticides against Livestock Sprays", is a clear introduction to this subject. However, some of the methods used sound unpleasant for the animals, and one wonders if alternatives could not be devised.

This is a useful reference work and the best chapters give excellent introductions to the subjects discussed. Unfortunately test-insects are not listed in the index.

W. A. L. DAVID

CONTROL OF PLANT GROWTH

Crop Production and Environment

By Dr. R. O. Whyte. New edition. Pp. 392+31 plates. (London: Faber and Faber, Ltd., 1960.) 63s. net.

THE title of this book is not a reliable guide to the contents. Some of the subjects discussed, for example, the morphology of stem apices, the biochemistry of reproduction and the effects of growth substances, extend into much wider fields than the relation between crops and their environment. On the other hand, the most important practical aspect of this relation—the dependence of crop yield on climate, seasonal weather and soil factors—is barely mentioned.

The purpose of the book is to summarize results of research on the physiology of plant growth and development published since 1946, when the first edition appeared, and to show their application in agriculture and horticulture. As in the first edition, the chief topic is control of morphological development, particularly flowering, by temperature and day-length, that is, vernalization and photoperiodism, but there is also some discussion of quantitative growth of field crops, and of the significance of leaf area as a determinant of yield. An account of equipment for growing plants in controlled environments ranges from commercial glasshouses to phytotrons. Twelve chapters deal with the physiology of growth of different crop species, and the "agricultural botanists, agronomists, crop ecologists, plant breeders and general biologists" for whom the book is intended will probably find this the more interesting and useful part.

The author's aim has been to give as much factual information as possible within the prescribed space; he has not attempted to write a critical review, nor to deduce general relationships from the mass of experimental data. The resulting narrative has no

clear pattern and few connecting threads, so it is difficult to read and still more difficult to absorb. Much of the text consists of quotations from the original papers, and their variation in style contributes to the lack of unity and cohesion. The figures and plates are used to squeeze in still more information in a compact form; often they are not mentioned in the text, and sometimes the descriptions in the legends are inadequate.

Although, as the author himself says more than once, this book is superficial and not comprehensive, it will be a valuable reference work, for there is no other that attempts to cover the same ground. It is thoroughly documented, and has a bibliography of about four hundred references.

D. J. WATSON

EARLY THOUGHTS ON PROGRESS AND PROFITS

Progress and Profits in British Economic Thought, 1650-1850.

By G. S. L. Tucker. (Cambridge Studies in Economic History.) Pp. vii+206. (Cambridge: At the University Press, 1960.) 27s. 6d. net.

MR. TUCKER provides a scholarly analysis of the course of the debate in Britain about the relationship between the return on investment and economic progress. It should be of great interest to those who ponder the attempts of societies to understand themselves.

It is a little curious that it is during the beginning of the story, in the second half of the seventeenth century, that the debate is closest to the kind of emphasis applied nowadays. For then men argued, more or less instinctively, about the ability of rulers to affect the course of events by manipulating an indicator, which might also be a determinant. Josiah Child and his kind were all for pushing down interest rates, to attain by synthetic means what the course of commerce had produced in Holland, with the idea that this would create the most favourable conditions for British commerce. But with Adam Smith, and especially Ricardo, the emphasis changed; the debate became more concerned with distribution than with growth. The author throws much light on how this occurred, though perhaps he does not sufficiently emphasize the restrictive nature of the full Ricardian theory, making the whole outcome depend on diminishing returns to agricultural effort. The only policy measure left to Ricardo and his school for the furthering of growth was the plea for free trade, so that the margin of cultivation could be thrown back to the New World. But with the next generation, though much Ricardian influence is still present, the problem of excessive capital formation has become pressing. Britain had arrived at a situation similar to that of the Dutch much earlier, but instead of plenty of capital guaranteeing progress the fear that it might be excessive gains ground, as the stresses mount in Britain in the late 1830's and the 40's. Thus J. S. Mill, Wakefield, Torrens and others begin to think in terms of the export both of capital and men, so that both may find better opportunities abroad, and may, in conjunction, reduce the cost of imported primary products to Britain. Here, at the mid-nineteenth century, Dr. Tucker's story ends; he might well continue it.

S. G. CHECKLAND

Electrolytic Conductance

By Prof. Raymond M. Fuoss and Prof. Filippo Accascina. Pp. ix+279. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1959.) 59s.

THIS book deals with the theory of electrolytic conduction as developed on the basis of the Onsager equation by Fuoss and Kraus and later workers of their school. Briefly, their treatment was to introduce the Bjerrum hypothesis of the formation of ion pairs into the theory of Debye and Huckel, and to extend the treatment so as to cover non-aqueous solutions. In 1955, Fuoss and Onsager solved the theoretical problem for a model in which the ions were represented by charged spheres instead of point charges. The resulting equation involved two arbitrary constants, the limiting conductivity of the Onsager equation and the ion size. Fuoss later extended the treatment to electrolytes in which the ions are associated into ion pairs, but the equation is limited to very dilute solutions. The authors say in the preface that they do not think there is any hope of extending the theory to higher concentrations, where they think the treatment must start from fused salts, which are supposed to be diluted with non-electrolytic material.

The theory is developed in the book, the necessary mathematics being first summarized in short chapters on such matters as vectors and tensors (restricted to Gibbs's dyadics), hydrodynamics, and statistical mechanics. The static phenomena such as activity coefficients are fairly simply disposed of. The difficulty begins when conductivities are considered. The relaxation field is extended to higher terms, then binary and higher associations of ions are brought in. In general, the mathematical treatment is clearly set out, but it would be a help to the reader if it were stated at the beginning of each chapter just what was to be done in it. The book is restricted to the particular theory stated, but it contains material useful in the study of the alternative theories, which are not considered.

J. R. PARTINGTON

The Physics of Electricity and Magnetism

By Prof. William Taussig Scott. Pp. xvi+635. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1959.) 70s. net.

ONE is conscious at the present time of the feedback from research and discovery to the matter and methods of elementary instruction, or, more accurately perhaps, of the need for such a cycle. Physicists, for example, while complaining that the younger generation is ill-versed in the principles developed in the seventeenth and eighteenth centuries, also take exception to syllabuses and treatments that date from somewhere about the middle of the nineteenth. But it is not easy to see how to improve matters by any process of mere addition of information; substitution would be even less effective. The problem is one of integration, and the volume under review, though not elementary in standard, adopts this very refreshing approach with success.

Prof. Scott, after explaining the general ideas of charge, field, and potential in the first chapter goes on to the physics of the metallic state in the second and the behaviour of dielectrics in the third. By chapter seven, he is introducing the idea of the magnetic field in terms of the Lorentz law of force

on a moving charge. The mathematical development, which is in itself ageless, is as firmly implanted in the pattern of modern physical thought as Maxwell's was in the physics of his day. The author claims that the book gives a sound logical basis for understanding the physics of electricity and magnetism, and this claim is justified. The level is about that of the honours degree.

G. R. NOAKES

A Degree Physics

By Dr. C. J. Smith. Part 5: Electricity and Magnetism. Second edition. Pp. vii+743. (London: Edward Arnold (Publishers), Ltd., 1959.) 45s. net.

THIS book contains what the author describes as the fundamentals of electricity and magnetism for general degree students. It can be recommended without reservation. Throughout, it shows the mark of the experienced teacher, who knows where stress should be laid and where difficulties lie for students. He pays proper tribute to the pioneers—Faraday, Curie, and so on—so that students can see how the various branches of the subject have arisen.

The M.K.S. system is not used because the author claims that it has no academic (as distinct from utilitarian) value. This is probably true; nevertheless, it is a pity that he has also rejected the idea of differentiating between the dimensions of B and H and of D and E , an offshoot of the M.K.S. approach. Thus, in discussing dimensions he has to say, for example, "if we suppress the dimensions of x " (p. 700) and that the equation $\mu = \mu_0 + 4\pi\chi$ is better than $\mu = 1 + 4\pi\chi$.

But this is a minor criticism in an otherwise admirable book. It is a pity that, on the grounds of expense, a chapter on electromagnetic waves could not be included; a treatment of this subject in the same vein as the rest of the book would have been invaluable.

H. LIPSON

Valency

Classical and Modern. By Dr. W. G. Palmer. Second edition. Pp. xi+244. (Cambridge: At the University Press, 1959.) 30s. net.

THE first edition of this book was published in 1944. It became deservedly popular as a good down-to-earth account of valency, with a pleasant historical flavour, and closely related to observable chemical behaviour. No less than three reprints were called for. Now Dr. Palmer has brought forward a new edition. It must be said at once that this new version preserves the admirable qualities of the older one; and the author has taken the opportunity to correct a few of the slips that had crept in. But, without extending the size of the book, he has added more information about the transition elements, the ubiquitous hydrogen bond and electron-deficient compounds. This additional material enhances the value of the book.

The author is at his best when describing, and collating, experimental results, and many of his tables of numerical data will be exceedingly valuable. But he is less confident with the more theoretical side of the field. Thus a false account of the energies of the molecular orbitals in oxygen still survives, the words 'ligand-field-theory' do not appear in the index, nor (I believe) in the text, and very little explanation is offered for the hydrogen bond. But these are minor blemishes in a useful and sensible account.

C. A. COULSON

TUNGSTEN-185 FROM NUCLEAR BOMB TESTS AS A TRACER FOR STRATOSPHERIC METEOROLOGY

By DR. HERBERT W. FEELY and PROF. JEROME SPAR*

Isotopes, Inc., Westwood, New Jersey

THE introduction of artificial radionuclides into the atmosphere by nuclear bomb tests has provided meteorologists with new tracers for the study of atmospheric circulation and mixing processes. In particular, the high-yield weapons that were detonated between 1952 and 1958, and which injected large quantities of radioactive dust into the stratosphere, have presented atmospheric science with several useful tracers for the study of stratospheric meteorology.

To account for the low water vapour content of the stratosphere, Brewer¹ had suggested the existence of an organized meridional circulation with air moving upward through the equatorial tropopause, then horizontally poleward at high levels, and sinking back into the troposphere in the polar regions. A similar circulation was later accepted by Dobson² to explain the ozone distribution in the atmosphere. Dobson, to account for the seasonal variation of ozone, suggested that cold air from high altitudes over the winter pole sinks to lower levels in the late winter or early spring, bringing high ozone concentrations with it. The 'Brewer-Dobson' circulation model was adopted by Stewart *et al.*³ as a reasonable explanation of the observed variations of radioactive fall-out with latitude and time. Machta⁴ and others⁵⁻⁸ have also found the predictions of the 'Brewer-Dobson' theory compatible with measurements of fall-out at ground-level. Hagemann *et al.*⁹ used the 'Brewer-Dobson' model to explain the observed stratospheric concentrations of carbon-14 from bomb tests, and Burton and Stewart¹⁰ employed it in their explanation of the stratospheric concentrations of the radon daughter products.

An alternative theory of the effective transfer processes in the stratosphere was proposed by Spar¹¹, who suggested that large-scale horizontal mixing (turbulent diffusion, 'Austausch') plays a dominant part in the dispersion of radioactive debris in the stratosphere. In the lateral mixing theory the 'gap' between the tropical and polar tropopauses is considered to play a significant part in the transfer, by horizontal motion, of debris from the stratosphere to the troposphere.

Data recently obtained by the High Altitude Sampling Program on the dispersion in the stratosphere of debris from the United States 'Hardtack' nuclear weapons tests of 1958 appears to be in contradiction to the 'Brewer-Dobson' model, but are apparently consistent with the hypothesis of lateral mixing as the most effective exchange agency. The data on which this conclusion is based are the measurements of the unique tracer tungsten-185, which was produced in several of these equatorial shots.

* Professor of meteorology, New York University.

The sampling programme¹¹⁻¹³ has involved the collection of filter samples of stratospheric air in a meridional-vertical plane in the western hemisphere extending from the North Pole to 57 degrees south. The samples are collected by Lockheed U-2 aircraft, and are analysed for fission products including strontium-90 as well as other artificial and natural radionuclides such as plutonium, tungsten-185, rhodium-102 and beryllium-7. The data on the distribution of tungsten-185 in the stratosphere are especially relevant to the attempts to describe stratospheric transfer processes.

About 95 Mc. of tungsten-185 were injected into the stratosphere during the 1958 'Hardtack' tests¹⁴ near latitude 12° N. between May and July of that year. Tungsten-185 decays with a half-life of 74 days, so that it is necessary for the geophysical analysis of tungsten data to correct for the radioactive decay rate. All the tungsten data referred to here have been corrected for radioactive decay to a common date of August 15, 1958.

So far as is known, tungsten-185 was only produced in significant quantities by the few 'Hardtack' weapons. It is therefore a unique tracer, having been injected at one place only, the Bikini-Eniwetok area at about 12° N., and within a limited time-interval, unlike strontium-90 which has been injected over a period of six years at high and low latitudes. The tungsten data therefore offer an excellent opportunity to study the dispersion of a cloud of radioactive particles injected into the tropical stratosphere.

The debris from the 'Hardtack' tests spread rather quickly through the stratosphere. By late 1958 tungsten-185 was included in the stratospheric debris which was falling out in north temperate latitudes¹⁴. Tungsten-185 was detected in most filter samples of stratospheric dust collected by the High Altitude Sampling Program on and after May 24, 1958.

Vertical profiles of tungsten-185 and strontium-90 (expressed in disintegrations per min. per 1,000 standard cu. ft. of air: abbr. d.p.m./1,000 s.c.f.) are shown in Fig. 1 for four ten-degree latitude belts for the period November-December 1959. The distribution of tungsten-185 at this time was similar to that which had existed as early as September 1958, except for the fact that the peak concentration and the vertical and horizontal gradients have diminished. During this entire period the maximum tungsten-185 activity has been located between 10° N. and S. and close to the 70,000-ft. level. (During July-August 1959 the maximum lay clearly below 70,000 ft. in the equatorial zone.) At higher latitudes the level of maximum tungsten activity is found at lower

Fig. 1. Vertical profiles of strontium-90 and tungsten-185 (corrected for decay to August 15, 1958) in the lower stratosphere during November-December 1959

Fig. 2. Mean distribution of tungsten-185, November-December 1959

altitudes, diminishing in height toward the Pole. Data for the southern hemisphere were obtained only up to August 1959. Up to that time the distribution of tungsten-185 was roughly symmetrical about the equator, but with somewhat lower activity in the southern hemisphere. This pattern differs from that of the strontium-90 shown in Fig. 1, which, at all latitudes, shows maximum activity at the maximum sampling altitude of the aircraft.

The tungsten-185 distribution is shown more clearly in the meridional-vertical cross-section for November-December 1959 (Fig. 2). Here can be seen the virtually stationary 'core' of the tungsten cloud over the equator, and the layer of maximum tungsten activity sloping downward toward the North Pole. The slope of this zone of maximum tungsten, it may be noted, does not parallel the isentropic (potential temperature) surfaces in this region of the atmosphere, for the latter are nearly horizontal. Fig. 3 is a schematic cross-section showing the relation between the layer of maximum tungsten-185 and the tropopause structure.

According to the 'Brewer-Dobson' model, tungsten-185 should have reached the lower polar stratosphere by moving upward into the high tropical stratosphere, migrating poleward at high altitudes, and then descending into the lower polar stratosphere. However, since 1958, and at least until April 1960, the highest tungsten concentrations have been found in the equatorial stratosphere at 65,000-70,000 ft., indicating no significant upward motion of the debris in that region. Furthermore, high concentrations of tungsten have never been found at the 65,000-70,000-ft. sampling altitudes in the polar stratosphere, indicating that the movement of this nuclide into the lower polar stratosphere, where the higher concentrations are found in these latitudes, has not been due to subsidence of air and debris from the high polar stratosphere.

The observed distributions of tungsten-185 suggest a lateral spreading by turbulent 'Austausch' from the latitude of injection, at about 12° N., into both the northern and southern polar stratosphere, as indicated by the arrows in Fig. 3. The lateral mixing appears to have occurred within a sloping layer which decreases in height toward the poles. The fact that the 'mixing surface' slopes more steeply than the isentropic surfaces may indicate the existence of a systematic sinking of the radioactive debris relative to the air as it mixes poleward, possibly by gravitational settling or some

other mechanism, or a systematic subsidence of the air itself as it mixes into the polar regions. There is no indication, however, of a large-scale subsidence of polar stratospheric air from very high levels.

The profiles of strontium-90 shown in Fig. 1 are consistent with the concept of lateral mixing, if there exists a zone of maximum strontium-90 con-

Fig. 3. Zone of maximum tungsten-185 concentration

centration which is broader and at a higher altitude than the zone of maximum tungsten-185 but roughly parallel to it. Such a distribution of strontium-90 was probably produced by the high-yield 'Hardtack' weapons in the summer of 1958. The high concentrations of strontium-90 found at high altitudes in the polar stratosphere may then be explained as the result of lateral spreading of this debris. Prior to the 'Hardtack' tests, our data indicated a distribution of strontium-90 similar to the present distribution of tungsten-185. Of course, the strontium-90 data are not as easily interpreted as the tungsten-185 data due to the presence of some strontium-90 from Soviet high-latitude tests.

The distribution of ozone in the stratosphere, which was accounted for by the 'Brewer-Dobson' model, may also be interpreted in terms of the mixing model presented here. Ozone is produced in high concentrations in the tropical stratosphere below 100,000 ft., the same region that received injections of strontium-90 from high-yield 'Hardtack' tests. According to Paetzold¹³, the relatively high ozone concentration found below 65,000 ft. in the polar stratosphere and the deficit of ozone found below 89,000 ft. in the tropical stratosphere, as well as the seasonal variations in ozone, suggest the existence of a meridional transport of ozone toward the poles in the layer from 50,000 to 80,000 ft. Such a transport may certainly be effected by lateral 'Austausch'.

The increase in the rate of fall-out of nuclear debris in the north temperate zone, which has been observed during the early spring of each year, is attributable, in part, to a rise in the concentration of nuclear debris in the lower polar stratosphere during the winter as a result of the influx of debris from lower latitudes. This influx occurs in response to increased rates of turbulent mixing within the winter stratosphere. During the late winter and early spring this material is released to the troposphere by turbulent mixing through the tropopause and through the tropopause gap, and by the raising of the tropopause with the onset of warmer weather. The early spring increases in fall-out rate in 1956, 1957, 1958 and 1959 were augmented, as Martell¹⁶ has suggested, by debris injected into the polar stratosphere during the latter half of the preceding year. As Walton¹⁴ has pointed out, however, fall-out in the north temperate latitudes

during the first six months of 1959 appeared to come from a well-mixed source, presumably an area of the lower polar stratosphere, which contained debris injected into the lower tropical stratosphere by United States tests in the summer of 1958 as well as debris injected into the lower polar stratosphere by Soviet tests during the autumn of 1958. Such a stratospheric source could have resulted only from extensive turbulent mixing between bodies of polar and tropical air during the winter of 1958-59.

It would appear that the data on the distribution of most natural and artificial tracers in the stratosphere (and data on the surface distribution of fall-out of stratospheric origin) can be explained as well by a stratospheric mixing and transfer model which invokes turbulent mixing as the most effective process as by one which invokes an organized meridional circulation. However, data on the distribution of tungsten-185 in the stratosphere can be interpreted much more easily in terms of the former model, although the exact configuration of the apparent mixing surfaces has not yet been adequately explained.

The High Altitude Sampling Program has been supported by the United States Defense Atomic Support Agency.

ORIGIN OF THE PACIFIC BASIN: A METEORITE IMPACT HYPOTHESIS

By E. R. HARRISON

Atomic Energy Research Establishment, Harwell, Berkshire

VERY little is known about the processes that have fashioned the major features of the Earth's surface. Of the many problems unsolved, perhaps one of the most intriguing of all is that of the origin of the Pacific Basin.

It is known that the lighter crustal layers, which form the continental land masses to a depth of 20-40 km., are relatively thin on the ocean floors and

in the particular case of the Pacific Basin are almost entirely absent¹⁻³. The Pacific Ocean itself has a mean depth of 5 km. and occupies almost half the Earth's surface; the greater density of its underlying rocks is consistent with the absence in the gravitational potential of any first harmonic terms about the axis of rotation⁴. It was pointed out by Suess in 1888 that an outstanding characteristic of the Pacific

is that it is surrounded by a variety of features which lie parallel to its coastlines. Among these features are the island festoons and the multiple arcs of deep-focus earthquakes, gravity anomalies, and ocean deeps. A further impressive characteristic is the seismic passivity of the Pacific Basin itself, which is in direct contrast with the continual tectonic activity in the surrounding regions where dissimilar crustal structures are in close contact and the land masses are folded as if by thrust against the denser and stronger mass of the Pacific Basin.

To explain such major surface characteristics it is proposed that the Pacific Basin was the seat of an immense explosion in the primitive Earth, and that the explosion was possibly due to a collision with a planetesimal or a satellite of approximately 100 km. radius. An attempt will be made to show that the explosion excavated a large crater of several thousand kilometres in radius and some hundreds of kilometres in depth. The great masses of material that were swept back and dropped at the rim of the crater formed the discontinuities of crustal structure and composition which survive to the present day and are responsible for the peripheral features of the Pacific Basin. Following the recovery of hydrostatic equilibrium there remained a shallow and permanent crater depression (because of the absence of the lighter surface layers) which is the present Pacific Basin.

There are very few theories which attempt to account for the absence of the lighter crustal rocks on the ocean floors and in the Pacific Basin. A well-known theory is that due to Fisher, who, in 1889, elaborated on the idea that the Moon originated from the Earth with the suggestion that the Pacific is the scar left by this event. The idea that the Moon originated from the Earth was further developed by G. H. Darwin with the tidal resonance hypothesis. However, detailed analyses, particularly by Jeffreys, have cast doubt on the whole idea that the Moon originally was in some way wrenched from the Earth. A particularly strong argument against such ideas is that, failing the coincidence of a third body in the immediate neighbourhood, the ejected Moon would most likely fall back and in any event could not become a satellite of the Earth.

In an alternative theory, Hills⁴ has more recently proposed that the lighter crustal rocks such as granite were concentrated into continental rafts by the convection currents that occurred while the Earth was solidifying from a molten state. A comparison is made with boiling jam in which the convection currents sweep the scum on the surface from the centre to the sides. There are a number of difficulties with any theory of this kind, among which are Urey's⁵ arguments in favour of formation of the Earth while in a relatively cold state. However, if the Earth was at some time in a molten state the present surface rocks, which are likened to the scum formed on jam, were not necessarily the first materials to solidify, but in all probability were the last. Most materials have a greater density in the solid than in the liquid phase; also, the melting points of silicates increase considerably with depth; hence it is highly unlikely that a solid crust of substantial thickness would first form and then float on a liquid or even a semi-liquid mantle. It would seem that the major event which led to the destruction of the surface symmetry happened while the Earth was in a solid state.

In any discussion of this kind the Moon's surface is of prime interest. The processes which formed the lunar surface may also have been active on the terrestrial surface in the past. But unlike the Earth's surface the salient features of the Moon have not been effaced by erosion. There is little doubt that the majority of the large craters on the Moon were formed by explosions and it is now agreed by most¹⁻³ (who have argued quantitatively in this field) that the most plausible explanation is that the craters were produced by the explosive impact of incident bodies of various sizes, compositions, and relative velocities, falling singly or in groups. Covering large areas of the Moon are the maria, which may be either lava floods or compacted fragmentary material presenting a similar appearance^{9,10}. The processes which produced the craters and the maria appear to have operated simultaneously; the numerous craters continually erupted and tended to obliterate the maria, and the maria less-frequently swept out and covered the existing craters. There is no reason for believing that there were not several cycles or even a continuous history of mutual obliteration in which at any instant, including the terminal period of the process, the Moon had in principle the same kind of surface features as it has now.

In 1893, Gilbert¹¹ argued strongly against a volcanic origin of the maria and was the first to point out that the evidence is consistent with the idea that the maria were also formed by collisions. He directed attention to the fact that Mare Imbrium, the largest of the maria, with a diameter of about 1,000 km., was surrounded by belts of mountains and radially directed furrows and splashed surfaces as if a great explosion had blasted material in all directions. Baldwin has given considerable support to this view and states that ploughed and splashed surfaces can be detected radiating from some of the other maria. Urey and Kuiper have developed the idea further, and the former ascribes the origin of Mare Imbrium to the oblique impact of a large meteorite of 100 km. radius.

Whether or not the explosive upheavals which formed the maria were plutonic or meteoritic in origin, the main suggestion is that the Pacific Basin was formed by a similar but even larger explosion. No known plutonic mechanisms appear to be adequate, and we shall therefore leave aside the question of a plutonic origin and proceed with the assumption that the Pacific Basin was formed by an explosive impact.

The multiple objects that were incident on the Earth and Moon some 10^9 years ago or more were not improbably the remnants of the birth processes peculiar to the Earth-Moon system. Either the objects were satellites of this system, or they were planetesimals which were swept up in some tens of millions of years¹²; or possibly a combination of both. In the first case the energy ϵE released per unit mass of a satellite on impact with the Earth is given by $\frac{1}{2} \leq \epsilon < 1$, where E is the escape energy of 6×10^{11} ergs gm.⁻¹ from the Earth; in the second case, the energy released per unit mass of a planetesimal in most cases is given by $\epsilon > 1$ and depends on the form of the orbit. If the object had a mean density of 3, roughly equal to that of the Moon, the total energy released by the collision was $10^{24} \alpha^2 \epsilon$ ergs, where α is the radius of the satellite (or planetesimal) measured in units of 100 km.

The physics of crater formation by explosive impact are complex, and are still in an initial state of development. In the case of large craters the following rather crude arguments give results which are possibly sufficiently accurate for the present purpose. It happens that for $\epsilon > \frac{1}{2}$ the meteorite has a relative velocity v which in many instances is greater than the propagation velocity of longitudinal waves in the Earth's outer layers, and a one-dimensional fluid treatment is adequate for the first stages of the impact. (This is not necessarily true for the Moon, and it seems likely that the maria are not true explosion craters, but are mainly compacted and sintered beds of the fragmented impacting body.) During the collision, shock fronts advance into the Earth and the meteorite, and behind the shock fronts a compacted region of high pressure and temperature builds up and moves into the Earth with a velocity of $\frac{1}{2}v$ (assuming that the meteorite and the outer layers of the Earth have the same density). When the shock front reaches the rear end of the meteorite, rarefaction waves develop and the explosion commences. From the conservation of momentum and energy one finds that at the instant the explosion commences the compacted region has a total mass twice that of the original meteorite, and a kinetic energy half that of the original meteorite; the remaining half of the kinetic energy has been converted into heat and other forms of internal energy in the compacted region. Following this instant, the one-dimensional model progressively breaks down as the compacted mass bores down into the Earth. However, we have that at least half the original kinetic energy of the meteorite is available for the explosion and is converted entirely into heat as the compacted region expands into a gas (the ionization energy of the intermediate plasma state is also eventually available as heat), and at the most only half the original kinetic energy is propagated into the Earth and uphurls large areas of the surface and sets the Earth into large-amplitude oscillations.

Gilvarry and Hill¹³ have calculated the temperature and pressure in the compacted region using an equation of state based on the statistical Thomas-Fermi model of the atom. However, it is essential to remember that the moment expansion commences their results no longer apply, and one finds that the temperature tends towards that of an ideal gas of 24,000 °K. for an average atomic weight of 20. From Gilvarry and Hill's calculations it is found that for $\epsilon \simeq 1$ the density in the compacted region prior to the explosion has been increased by 8/5, and therefore the shock fronts have velocities of $4v/3$ (downwards) and $-v/3$ (upwards), and the meteorite plunges into the Earth a distance equal to $3/4$ of its diameter before the explosion begins; or for $\epsilon \simeq 3$, the density is increased by 2, the shock velocities are v , 0, and the meteorite penetrates a distance of 1 diameter.

The complexity of the phenomena involved makes it extremely difficult to estimate the dimensions of the crater formed by an explosion. In general, the crater is large in comparison with the size of an exploding missile. The extrapolation of known data on crater dimensions by the empirical scaling rules used in nuclear explosions¹⁴ means that for very large craters the energy released approaches, and can even be less than, the necessary work done against the gravitational field. If W is the energy released, it is usual to assume that the crater radius varies as $W^{1/3}$

and the depth as $W^{1/4}$. It follows that the work done against the gravitational field is proportional to volume $\times$ depth, or $W^{7/8}$. Since the work done must be less than W there is a limit beyond which these scaling rules cannot be applied. This limit occurs for very large craters where the gravitational field plays the dominant part in determining their size. Baldwin's empirical formulae, which are quadratic in logarithms and therefore yield indices which are functions of the crater size, also encounter, so it appears, a similar difficulty, particularly when it is remembered that the final depth of a large crater may be very much less than its initial depth. It is also important to remember that in the case of very large craters the final depth (which is the parameter used in the scaling rules and the empirical relations), after the recovery of hydrostatic equilibrium, cannot depend solely on W but must also depend on the density gradient at the surface of the Earth; if there is no density gradient the final depth is zero and is independent of the value of W .

It would seem plausible, therefore, to assume that for an explosion of the magnitude and nature that we are discussing the initial crater dimensions are determined primarily by work done against the gravitational field. Thus, if all the kinetic energy $(4/3)\pi\alpha^3\rho_s\epsilon H$ of the meteorite is expended in excavating a crater of radius R , the minimum work done against the gravitational field for a conically shaped crater (that is, the depth relative to the Earth's curved surface changes linearly) of maximum depth d is $\pi R^2 d^3 \rho_g / 12$. If we now suppose that the maximum depth is approximately the radius of the satellite, or $d \simeq \alpha_s$, then it follows that:

$$R^3 \simeq 16\epsilon\alpha_s\alpha_s\rho_s\rho_g^{-1} \quad (1)$$

since $H = g\alpha_s$. This estimate represents an upper limit to which crater radii tend for very large explosions. It neglects the effect of the curvature of the Earth's surface, and also the possibility that material escapes from the Earth. We have seen that the internal energy density of the compacted region is $\frac{1}{2}\epsilon H$, and for $\epsilon > 2$ there is the possibility that a fraction of the ejected material encircles the Earth and is deposited as rays similar to those observed radiating, for example, from Tycho; also for $\epsilon > 4$ it is not unlikely that some of the ejectamenta escape from the Earth. In any event, the existing proto-atmosphere would be blown away either completely or partly from the Earth; this would expend only a negligible amount of the available energy if the total mass of the proto-atmosphere was of the same order of magnitude as the mass of the present atmosphere. From the abnormally low abundances of the inert gases it is known¹⁵ that at some stage the Earth must have lost its original atmospheric envelope, and that the present atmosphere is of secondary origin and was formed by chemical and photosynthetic processes acting on juvenile gases from the Earth.

Assuming that $\epsilon \simeq 1$, and $\rho_s \simeq \rho_g$ for the surface layers of the Earth, we find that for meteorites of radii 100 km. and 500 km. the crater radii are approximately 3,000 km. and 7,000 km., respectively. It is remarkable that Baldwin's empirical formula, which is constructed from the known data of comparatively small explosions, gives crater radii of approximately 2,500 km. and 7,000 km. A crater of radius 3,000 km. is possibly adequate to account for the size of the Pacific Basin. The hypothesis therefore is

that a satellite or planetesimal with a radius of approximately 100 km., and $\epsilon \approx 1$, penetrated a distance of 100–200 km. and exploded; the expanding gases released an energy of the order of 10^{24} ergs and swept back the surface layers to form a crater, at the edge of which large quantities of material were dropped; almost simultaneously there was hydrodynamic flow in the Earth caused by the subsiding rim and the rising crater floor, and the gravitational energy released caused considerable melting over a wide area; finally, there remained only a relatively shallow depression surrounded by a slightly elevated 'land mass' of lower density and dissimilar composition.

Perhaps it should be emphasized that an explosion of this magnitude bears no comparison with any known terrestrial event. In terms of present-day nuclear weapons the total energy released was of the order of 10^{11} five-megaton hydrogen bombs, and over an area of 3,000 km. radius this amounted to a mean energy density of approximately 1 atom-bomb (20 kiloton) per square metre. Using Einstein's mass-energy relation, it is found that the total energy released is equivalent to a loss of mass of 10^{13} gm., or a mass weighing approximately 10^7 tons.

Of all the assumptions that one might make the simplest is that the collision was made by a planetesimal, such as one of the large asteroids. In the past there may have been many such bodies with orbits close to that of the Earth. This point of view raises the possibility that there may have been multiple encounters with the Earth of the particular kind that we have considered with $\epsilon > 1$. It is then logical that one should go even further than has been implied so far in this discussion, and ask: Is it conceivable that all the ocean basins, underlaid by rocks denser than the surrounding land masses, are crater depressions produced by explosive impacts and have in common the same origin as the maria on the Moon?

As an alternative approach it is not improbable that the Earth once possessed more than one natural satellite, and that the particular collision we have considered was made by a satellite that was deflected from its normal orbit by a third body such as the Moon, or was sufficiently close to lose angular momentum by tidal friction. In the case of several satellites a close examination of the mechanics involved is necessary to establish whether the idea of multiple collisions with the Earth is at all valid. The possibility that the early Earth possessed two 'moons', which moved apparently in opposite directions across the sky in very much the same way as Phobos and Deimos appear to move from Mars, is sufficiently intriguing, however, to consider briefly some conditions for a collision caused by tidal friction.

Quite what the conditions were like for tidal friction is not known; but according to Jeffreys's calculations the Moon was at approximately 0.6 of its present distance some 4×10^8 years ago. For a satellite to spiral inwards it must be close enough to rotate faster than the Earth's surface, or since the day was then only 7 hr. long, this requires that the satellite's distance r_s satisfied $r_s < 3a_e$. If the conditions for tidal friction were the same then as now, the time taken by a satellite of 100 km. radius to reach the Earth would not exceed 10^6 years and would be considerably less in the event of tidal resonance. But also any satellite at the present moment at a

distance of approximately $r_s < 7a_e$ spirals inwards because of tidal friction. It follows that if initially the satellite was at a distance $3a_e < r_s < 7a_e$, and if the tides raised by the Moon were larger than those raised by the satellite, then the satellite would first have spiralled outwards and when the Earth's surface rotated faster would then have spiralled inwards. The condition that the Moon raised the larger tides is that $a_s/r_s < a_m/r_m$, or the sufficient condition is that the satellite had a radius of less than 130 km. At distances less than the Roche limit of 2–3 Earth radii a fluid satellite has no equilibrium configuration, and therefore it breaks up. But in the case of a solid satellite one finds that the maximum differential force due to the Earth's gravitational field is less than the internal strength (assuming a critical stress difference of 10^8 dynes cm.⁻²) for radii of less than 120 km.; therefore a solid satellite with a radius smaller than 120 km. does not break up. A more detailed analysis by Jeffreys¹⁶ gives substantially the same result. It seems therefore that a satellite of approximately 100 km. radius at an initial distance of less than approximately 7 Earth radii would at some time in the past have struck the Earth, would also have remained a coherent body without fracture as it approached the Earth, and in the final collision could have released perhaps just sufficient energy to account for the Pacific Basin. It must be emphasized that this rudimentary picture is totally inadequate if one adopts the point of view that there has been more than one large collision with the Earth. As we have seen, a single such collision is sufficient to affect profoundly the fluid envelopes in which the tidal friction occurs; without a closer examination of the problem one might say that this reason alone weakens the idea that several collisions were due to tidal friction.

Baldwin has made the suggestion that there should be geological evidence in the pre-Cambrian rock strata of repeated meteoritic impacts with the Earth. In this discussion I have taken the suggestion one stage further. On making the reasonable assumption that at least one body has collided with the Earth comparable in size with that responsible for producing Mare Imbrium, it follows that the evidence for such a collision should be immediately apparent even nowadays if it is looked for on a sufficiently large scale. It is proposed that the Pacific Basin has many characteristics that strongly suggest an origin of this nature.

EXPERIMENTS WITH DIVING SEALS*

By PROF. R. J. HARRISON

The London Hospital Medical College, University of London

ALL mammals can withstand complete submersion in water for a little while; but some forms are able to remain submerged at considerable depths for remarkable periods of time. It will be obvious that there are few accurate observations on the maximum length of time for which any mammal can remain under water: it would mean diving the animal to extinction. The following is a list of record durations of dives that have been taken from Scholander¹, Scheffer² and Harrison and Tomlinson³:

Pigeon	1 min.	Ringed seal	20 min.
Hen	3 min.	Common seal	28 min.
Duck	17 min.	Porpoise	12 min.
Penguin	7 min.	Blue whale	50 min.
Water rat	2 min. 17 sec.	Sperm whale	75 min.
Rabbit	3 min.	Bottle-nosed whale	120 min.
Dog	4 min. 25 sec.	Man (pearl and sponge divers)	2 min. 30 sec.
Muskrat	12 min.		
Grey seal	20 min.		

The maximum depth reached by a diving animal is as difficult to determine as the duration of a dive. The literature is full of anecdotes of fouling of cables, hooks and nets by seals and whales at immense depths; but there is no evidence that the animals were not dying before they became entangled or whether they would have survived had they returned to the surface. The following are a few recorded deep dives (see references for duration):

Penguin	at least 12 m.	Experimental dives
Weddell seal	92 m.	Diving below ice
Common seal	92 m.	Experimental dives
Grey seal	146 m.	Caught on hook
Harp seal	278 m.	Caught on hook
Porpoise	20 m.	Line attached
Fin whale	355 m.	Line attached
Sperm whale	900 m.	Entangled in cable
Man	166 m.	Flexible suit with special breathing mixture

All evidence indicates that young seals and whales cannot equal the performance of adults. Scholander¹ records that a 4-month-old grey seal pup on its first swim in deep water dived to 22 m. for a total time of 1 min. A 6-month-old hooded seal dived spontaneously to 75 m. and remained submerged for more than 4 min. A young hooded seal, which had been submerged the previous day for 18 min., was weighted by Scholander and submerged to a depth of more than 300 m. in 3 min. It was drawn to the surface immediately after reaching that depth over a period of 9 min. The seal was reflexless on return to the surface, its heart beat very weakly, one pupil was widely dilated, one a short slit, the nostrils were firmly closed and it died shortly afterwards. No water was found in the lungs, but there was an abundance of air bubbles in the mesenteric arteries. Death was presumed to be due to air embolism.

Our experiments were carried out on pups, yearlings and adolescent common seals (*Phoca vitulina*) obtained from the Wash, East Anglia, through the kind co-operation of the Eastern Sea Fisheries Joint Committee and the Hydrographic Survey Ship, H.M.S. *Scott* (Commander H. R. Hatfield, R.N., then

in command). Diving performance was assessed by immersion in a shallow tank, at sea, and under water or in air in a pressure-chamber capable of simulating a pressure of 300 ft. of water. Seals were secured to a board in a fashion similar to that described by Scholander¹, or in a specially designed lace-up 'Terylene' harness to enable free-swimming to take place at the end of ropes. Leads were connected from axillary electrodes to a portable Elmquist electrocardiogram. When required, animals were anaesthetized with 3-10 ml. of a solution of 1 gm. in 40 ml. sodium thiopentone injected into the extradural vertebral vein as if performing a lumbar puncture. Anaesthesia was afterwards maintained by introducing a Magill endotracheal tube (child's size) and administering nitrous oxide and oxygen.

Investigations of heart- and respiratory-rate were made on pups and young seals out of water, and the heart-rate was recorded during all experimental dives. The animals were secured as loosely as possible to a board or harness and were not anaesthetized during the dives unless specifically stated. No animal was 'dived' again unless the heart-rate and behaviour had returned to conditions prevailing at the beginning of the first dive.

Heart-rate Surfaced

This displays considerable variation, and even irregularity, in all animals whatever their age and whether or not they have recently dived. Young pups have a resting heart-rate of 90-180 beats per min.; in 2-3-year-old adolescents it varies from 75 to 180 beats per min. Proximity to the investigator or indication to the seal that it is about to dive (by submerging it a number of times for a few seconds) does not unduly influence the heart-rate. Any tachycardia that resulted from a struggle to secure the seal to a board, or in its harness, soon subsided and seals often went peacefully to sleep during a pause in a diving programme.

Respiratory-rate out of water is comparatively regular at 18-20 per minute, in both pups and adults. It is less regular when the seal is immersed in a harness with only its nostrils above water. The heart-rate increased from 112 to 144 when a seal was immersed suddenly up to its neck, head still above water, and fell to 120 after 5 min. It occasionally slowed from 120 to 60 for a few seconds following a respiratory pause longer than normal. This slowing of the heart associated with changes in respiratory-rate has been described also by Irving, Solandt, Solandt and Fisher⁴ and Irving⁵. Forceful closure of the nostrils and mouth of a seal out of water (so as to prevent respiration) caused a fall in heart-rate from 130 to 80 after 5 sec., to 43 after 22 sec., to 15 after 68 sec., and was followed by violent struggling which prevented further recordings. One yearling common seal was anaesthetized (with thiopentone, intubated, and then nitrous oxide and oxygen mixture used to continue the anaesthesia) and an attempt was made to determine the effect variations in respiratory-rate

* Substance of a Friday Evening Discourse delivered to the Royal Institution on November 11.

would have on heart-rate. Increasing the respiratory-rate artificially to 40 for a period of 2 min. had no appreciable effect on the heart-rate. The respiratory-rate was then lowered to 5; after 1½ min., when the heart-rate had dropped to 17, the animal collapsed, but was later resuscitated.

Tweaking the vibrissae caused episodic slowing of the heart-rate to 75 beats per minute for a few seconds; smacking the face raised the rate to 165 beats per minute. Throwing cold water over the face had little effect on the heart-rate.

Shallow Dives

Animals were 'dived', secured on a board, for periods of up to 28 min. In a dive of this length, intermittent struggling started at 15 min. and became extreme during the last minute so the animals were brought to the surface. The diving bradycardia did not develop as rapidly as in *Halichoerus*¹; the slowest heart-rate (6 beats per minute) occurred between 1 and 3 min. after diving. Thereafter the heart-rate gradually increased as time passed. The degree of bradycardia and the rate at which it developed were not significantly affected by the rate at which the heart was beating before the dive commenced. Repeated diving of the same animal (after a short recovery period of a few minutes) did not influence the rate of onset, degree of bradycardia or recovery behaviour. There was always a recovery tachycardia lasting for 5–10 min. after a dive of more than a few minutes. The slowest and longest lasting bradycardia was observed in older seals: the bradycardia also developed more rapidly.

A two-year-old seal was secured in a harness that left its head, four flippers and tail free; guide ropes and electrocardiograph leads were attached. The animal swam freely in a shallow tank, and dived for periods of several minutes. The heart-rate showed changes similar to those recorded when the seal was secured to a board. It was noticed that the seal exhaled when it broke the surface after a short shallow dive; this observation has been frequently confirmed by us and is also mentioned by Harrison Matthews⁶. Another young seal behaved similarly in a harness when allowed to swim in the sea. It towed a small dinghy containing two men with ease at about walking speed, and afterwards towed a skin-diver for a short distance under water.

A seal secured to a board was prepared for diving in a shallow tank; before diving and throughout the dive it was forcibly prevented from opening its nostrils or mouth. The heart-rate was 144 beats per minute on the surface (nose and mouth closed) and fell to 24 beats per minute after 30 sec. It remained at that rate for 75 sec., after which it struggled so violently to exhale that no further recording was possible.

Deep Dives

Three types of experimental diving were carried out: (a) pups a week old were lowered into the sea on a board; (b) two-year-old seals were placed in a tank filled with water inside a pressure chamber and the air pressure increased by stages to depths equivalent to up to 80 ft.; (c) two-year-old seals similarly secured were taken rapidly to 300 ft. and kept there for periods up to 5 min.

The pups showed an immediate bradycardia to between 10 and 16 beats per minute, but within a

few minutes under water the rate began to rise to 30 beats per minute. The older animals displayed an immediate bradycardia to 4–15 beats per minute, which was maintained for 2.0–5.0 min. at depths in the pressure chamber equivalent to up to 200 ft. There was no indication in the older animals of a gradual decrease in the bradycardia as the dive progressed at a constant depth. There was, however, an increase in heart-rate as the animal returned to shallower depths. The pups often showed a marked decrease in bradycardia after quite a short period (1–3 min.) at only 20 ft. There was no noticeable change in the bradycardia of adolescent seals in dives of short duration even at 200 ft. One young seal, taken to about 100 ft., managed to raise its nostrils above the water in the pressure tank on return when at 50 ft. It appeared healthy immediately after the dive, and carried out shallow diving during the ensuing weeks without ill-effect. Three months later the seal became anorexic, lost weight and was killed. Extensive surgical emphysema was seen in the lungs, thoracic wall and vertebral venous system at post-mortem examination. It was concluded that the animal had inhaled air under pressure and ruptured a lung during the return to the surface.

A two-year-old seal was taken rapidly to a depth of 300 ft. in 4 min. 30 sec. It remained at this depth for 1 min. 20 sec. and returned to the surface by stages, pausing for 30 sec. at every 50 ft. to make electrocardiograph recordings. On return to the surface the respiratory-rate was 30 per min.; the animal appeared fit and active, and displayed no signs of 'bends'. The same animal was 'dived' to 300 ft. the next day and kept there for 5 min. Towards the end of this period the cardiac complex on the electrocardiographic recordings indicated some degree of physiological 'defeat'. The animal was returned to the surface, and its heart was beating slowly on removal from water. Its pupils were dilated, muscular movements were weak. The heart stopped a few seconds later, and the animal could not be resuscitated. At post-mortem no evidence of air embolism, lung damage or haemorrhage could be detected. It is possible that the animal suffered a 'squeeze' at this depth such that the heart could not contract fully and cerebral anoxia followed.

Every seal was observed to exhale air when or just after it was immersed in water, and again later as the pressure increased in the chamber.

Exposure to Increased Air Pressure

It was considered to be of interest to investigate the effect on a seal of simply exposing it to a steady increase of air pressure simulating depths equivalent to those it had 'dived' when under water. Two-year-old seals were placed in a pressure chamber and allowed to breathe naturally as the air pressure was increased. The respiratory-rate was assessed by counting the nostril openings over periods of half a minute. Increased air pressure equivalent to a depth below water of 200 ft. caused a bradycardia from 120 to 30. It was not sustained, however, and the heart-rate rose to 150 for periods lasting up to 5 sec. The increase in air pressure caused the respiratory-rate to slow from 24 to 8, and it was noticed that this was correlated with the periods of most marked bradycardia. Increase in air pressure to depths equivalent to 30–80 ft. caused little slowing of the heart-rate and no disturbance of respiration. The seals were in no way embarrassed by exposure to

increased air pressure, but did seem puzzled at the strange sensation. It appeared that only when the seal held its breath was there any heart slowing, again indicating that the bradycardia is linked with interruption of regular respiration.

Stimulation and Section of the Phrenic Nerve

A thick, striated muscle sphincter is present on the posterior vena cava immediately cranial to the diaphragm in all seals we have examined. It is supplied by branches of the right phrenic nerve*. To ascertain the effect of closure of the sphincter the posterior vena cava was clamped just caudal to the liver in an anaesthetized pup: this procedure had no effect on the heart-rate in a surfaced animal. The right phrenic nerve was cut in the neck under anaesthesia in several young seals and they were afterwards allowed to recover. The animals were 'dived' a few days later. In all there was an eventual bradycardia similar to that in normal animals, but the onset of the bradycardia was delayed. Stimulation for short periods of one or both phrenic nerves had no effect on the heart-rate in surfaced anaesthetized animals.

Stimulation and Section of the Vagus Nerve

Stimulation of the intact right vagus of an anaesthetized pup resulted in slowing of the heart-rate from 120 to 22, with immediate recovery to 120 on cessation of stimulation. Stimulation of the intact left vagus resulted in disappearance of the ventricular complex on the recording: *P* waves

continued to occur at 120 a minute. Stimulation of either vagus in an anaesthetized adult seal completely abolished the heart-beat for the period it was applied.

Section of the right vagus in the neck in anaesthetized pups caused no change in the heart-rate surfaced (180) and a fall to only 100 on diving. The beats were irregular. Section of both vagi in pups caused no change in the heart-rate surfaced: in an adult the rate increased from 60 to 90. In short dives other anaesthetized pups with bilateral vagal section showed no slowing of the heart. Another was anaesthetized and both vagi were exposed; it was then 'dived' and after the heart-rate had fallen to 24, both vagi were sectioned with the seal under water. There was an immediate rise in heart-rate to 156 which persisted for the remainder of the dive and after surfacing.

Discussion of the significance of some of these findings is given by Harrison and Tomlinson³; the parts played by various vascular modifications in seals is discussed by Harrison and Tomlinson⁷ and Barnett *et al.*⁸. Further observations and discussion will be published shortly.

OBITUARIES

Dr. Hugh Scott, F.R.S.

DR. HUGH SCOTT, distinguished entomologist and biogeographer, died on November 1 at his home at Henley-on-Thames, at the age of seventy-five. He was born on September 16, 1885, the elder son of William Edward Scott and was educated privately and at Trinity College, Cambridge, where he was an exhibitioner and obtained a first in the Natural Science Tripos, Part I, in 1906. He received his Sc.D. in 1919.

At Cambridge Scott was deeply influenced by the training he received from Dr. David Sharp, whom he succeeded as curator of the Zoological Museum. In 1908 he joined the Second Percy Sladen Trust Expedition to the Indian Ocean and made an extensive collection of insects in the Seychelles. Scott afterwards organized the study of the collection by specialists, and himself undertook a considerable part of the work on the Coleoptera. Rarely, if ever, has a collection been so completely studied. With characteristic tenacity Scott saw the work through to completion and analysed the results in a summary of the faunal relationships of the Seychelles which is a model of clarity.

His experiences with the Seychelles fauna aroused an enduring interest in biogeography which influenced all his subsequent work. His special interest lay in the fauna of that area including East Africa and south-western Arabia where the Palaearctic and Ethiopian faunal elements meet and overlap. To

further this work Scott made four long collecting expeditions in the area: to the central highlands of Abyssinia during 1926-27, the Aden Protectorate and Yemen during 1937-38, the Gughé Highlands in southern Abyssinia during 1948-49 and the Simien Mountains in northern Abyssinia in 1952-53. The extensive collections of insects and plants which resulted from these journeys provided information on areas, the fauna and flora of which were previously almost unknown. The expedition to south-western Arabia was, for example, the first in the area since that of Niebuhr in 1762. These expeditions were prepared and carried out with great thoroughness and attention to detail, and great credit is due to Scott for the tenacity with which he sought his objectives in the face of physical disability, chronic ill-health and the political obstacles of those troubled regions.

In 1930 he was appointed assistant keeper in the Department of Entomology, British Museum (Natural History), a position that he held until his retirement in 1948.

In addition to his work on the systematics of Coleoptera, Scott was an authority on the Nycteribiidae, the louse-like, wingless flies which parasitize bats. He was also the author of several works on the fauna associated with the giant lobelias and the tree senecios of the East African highlands, and on the peculiar and extensive fauna of the leaf axils of the Bromeliaceae. He also wrote a number of valuable works of a geographical nature and a book on the

expedition to south-western Arabia entitled "In the High Yemen" (1942). During the Second World War he was the chief author of the naval intelligence "Handbook on Western Arabia and the Red Sea".

He was elected a Fellow of the Royal Society in 1941, an Honorary Fellow of the Royal Entomological Society of London in 1954, and was an original member of the Entomological Research Committee formed by the Colonial Office in 1909, which later developed into the Imperial Bureau (now Commonwealth Institute) of Entomology.

Scott will be remembered by all who knew him as a kindly, courteous and deeply learned man. He was possessed of a deep religious conviction, a fact which influenced his life to a high degree.

In 1913 he married Beatrice Emily Streatfield (who died in 1947) and leaves a son and daughter.

E. B. BRITTON

Dr. A. B. Edwards

AUSTIN BURTON EDWARDS was born in Melbourne in 1909 and educated at the Caulfield Grammar School. He graduated from the University of Melbourne with first-class honours in geology and was awarded the Howitt natural history scholarship in geology and the Bartlett scholarship. After the publication of the first two of the 128 contributions to geological science with which he is identified either as sole or joint author, he was awarded an 1851 Exhibition which enabled him to continue his studies in London at the Imperial College of Science and Technology, where he obtained his Ph.D. in 1934.

He won his university half-blue in football at Melbourne and his colours in athletics at the Imperial College; his athletics background was of great value to him in his geological work, much of which was performed in mountainous terrain.

On returning to Australia he joined the Mineragraphic Section of the Commonwealth Scientific and Industrial Research Organization, which maintains close relationships with the Geological Department of the University of Melbourne. Thus commenced a long association with the officer-in-charge of the Section, Dr. F. L. Stillwell, whom he succeeded in 1953. His early work with the Section produced a series of studies of Australian ores and ore deposits which was extended to the examination of mill products and mill tailings and eventually to smelter products such as mattes, speisses and slags. At the same time he sustained a keen interest in petrological problems and completed various papers begun in London, of which the more important were his studies on the tertiary volcanic rocks of Central Victoria and the differentiation of dolerites of Tasmania. In 1937 he shared with Prof. R. D. Wright the David Syme research prize of the University of Melbourne. He gained his doctorate of science in 1942.

His first independent mineragraphical task was the study of the occurrence of manganese in iron ore of Iron Knob in South Australia, later extended to the iron ores of the Middle Back Ranges. This was the first of a series of studies which culminated in the recognition and discovery of the oolitic iron ores in the Northern Territory and Constance Ranges in Queensland.

As the scope of work of the Mineragraphic Section widened, Dr. Edwards made contributions to sedi-

mentary petrology, geochemistry, meteorites and geomorphology. The sedimentary petrology commenced with a study, jointly with G. Baker, of the Jurassic arkoses in Victoria, later extended to the Mesozoic and Tertiary sediments of the Aure Trough, Purari Valley and the Wahgi Valley in Papua. His interest in geochemistry arose in the past few years from studies of the selenium content in sulphide deposits and the distribution of cadmium, manganese and iron in Broken Hill sphalerites. His descriptions of meteorites were a natural extension of his mineragraphical work, while his interest in geomorphology absorbed him during his vacations.

Lecturing in the University of Melbourne on mining geology between 1941 and 1953, his interest was roused in Victorian coal. Subsequent papers on Wonthaggi and Victorian brown coals elevated him to a position of authority on brown coal and resulted in a request from the State Electricity Commission to act as geological consultant. He allocated his consultant's fees to the purchase of equipment for the Mineragraphic Section.

In 1946 a postgraduate course was provided by the Geological Department of the University of Melbourne for eight Indian graduates. Dr. Edwards contributed to this course a series of lectures on mineragraphy and ore textures. These lectures provided the basis for his book, "Textures of Ore Minerals", which the Australasian Institute of Mining and Metallurgy published in 1947 and which met with such world-wide success that the demand quickly exhausted the first edition. A new and enlarged edition (1954) was exhausted in 1960, and further reprinting was in progress at the time of his death.

In preparation for the Fifth Empire Mining and Metallurgical Congress in Australia in 1953, Dr. Edwards initiated a symposium on the geology of Australian ore deposits. It was organized by a committee appointed by the Australasian Institute of Mining and Metallurgy with Dr. Edwards as chairman. The result was a volume comprising 135 articles contributed by the leading geologists in the Commonwealth, which were edited by Dr. Edwards, with the gaps filled in with his own editorial contribution. He served as assistant editor of the *Proceedings* of the Institute until his departure overseas.

Ore minerals and their textures was the subject chosen by Dr. Edwards for the Clarke Memorial Lecture to the Royal Society of New South Wales in 1952. The last honour received by him was the award of the Society's Clarke Memorial Medal in 1960.

He was a member of the Council of the Australasian Institute of Mining and Metallurgy, Corresponding Fellow of the Edinburgh Geological Society, Foreign Member of the Mineralogical Society of India, and observer for 1958-61 for the Commission on Geochemistry of the International Union of Pure and Applied Chemistry.

In preparation for his overseas tour he acquired a knowledge of spoken Italian. He left with his wife on August 25 but died in Rome.

With his death Australian geological science suffers the loss of a brilliant and energetic scholar whose clear thinking and rapid grasp of a problem was a constant help and guide to all associated with him. This loss, at the height of his career, is most keenly felt, both throughout Australia and overseas.

F. L. STILLWELL

NEWS and VIEWS

Electrical Engineering at Edinburgh :

Prof. W. E. J. Farvis

MR. FARVIS, senior lecturer in applied electricity and head of the postgraduate school of electronics and radio in the University of Edinburgh, has been appointed to the newly established chair of electrical engineering. He graduated B.Sc. from the University of Bristol in 1936, with first-class honours in electrical engineering. After junior teaching appointments at Dundee Technical College and University College, Swansea, he joined the Telecommunications Research Establishment in 1940, working first on new decimetric radar. The following year he transferred to counter-measures work for the radio defence of London, and for the remainder of the War led a group developing and using new ground and air interception devices. Immediately before the end of hostilities he was one of a team sent to Europe to investigate German radio and radar war-time research. In 1945 he returned to Swansea as lecturer, and in 1947 took the external B.Sc. degree of the University of London in physics. He was appointed lecturer at the University of Edinburgh in 1948, and afterwards senior lecturer. During his twelve years in the Engineering Department there Mr. Farvis has evolved a new electrical engineering degree curriculum, founded the postgraduate diploma course in electronics and radio (now in its eleventh year) and built up a research school on various types of gas discharge. His personal research has been in high-current arcs and fundamental problems associated with power-circuit interruption, interests which began during his student training at the switchgear works of the British Thomson-Houston Co. He took part in the official British programme for the International Geophysical Year, setting up stations in Shetland and Edinburgh for recording the absorption of galactic radio noise. This work, sponsored by the Royal Society, is still continuing in Edinburgh.

The British Industrial Biological Research Association

IN a written answer in the House of Commons on November 28, Sir David Eccles, as representing the Minister for Science, said that the British Industrial Biological Research Association was not designed to supplement the work of the Department of Scientific and Industrial Research. It had been formed by industry as a co-operative industrial research association, and its new laboratories were to be sited at Leatherhead on land adjacent to existing laboratories of the British Food Manufacturing Industries Research Association to facilitate the sharing of facilities. In answer to further questions on December 1, Sir David said that the laboratories would cost £56,000, and the main purpose of the facilities was to investigate the effect on health of substances used in food, or which may find their way into food from such things as pesticides, packaging materials or utensils. The site had the additional advantage of proximity to the Medical Research Council's Toxicological Research Unit at Carshalton. Questioned about the Minister's proposal to close the Research Station at Greyhope

Road, Aberdeen, the Joint Parliamentary Secretary to the Ministry of Agriculture, Fisheries and Food, Mr. W. M. F. Vane, stated that the work proposed at Leatherhead was entirely different from that done at Aberdeen. During the past twelve months the latter had included: the installation and operation of the Mark I commercial prototype accelerated freeze-drying cabinet loaned from Chicago; production of field-trial samples of various foods processed by the accelerated freeze-drying method, and of experimental rations for large-scale trials by the three Armed Services; work on the quality and storage life of dehydrated foods; research into problems of flavour in vegetable products; investigation of enzyme activity in dehydrated raw meats with low-moisture content, and of the reasons for the deterioration of dehydrated raw meat; investigation of the mechanism of oxidative rancidity and of the application of free-radical acceptors to the inhibition of oxidative rancidity induced by radiation. Three other projects had been undertaken with grants provided by the United States Department of Agriculture, including the investigation of new antioxidants, of the freezing and drying of muscle tissues, and of the significance of carotenoid breakdown in the deterioration of fruits and vegetables.

Tax Assessment for Scientific Societies in Britain

CLAUSE 9 of the Rating and Valuation Bill, which received its second reading in the House of Commons on November 30, gives effect to the recommendation of the Pritchard Committee that the total exemption from rates given by the Scientific Societies Act of 1843 to societies established for the purposes of science, literature or the fine arts, exclusively, should be terminated. In moving the second reading of the Bill, the Minister of Housing and Local Government, Mr. H. Brooke, after a tribute to the work of the Pritchard Committee, said that the Government proposed to follow the report in this difficult matter. The definition in the 1843 Act had proved so difficult to apply that he doubted if anyone would advocate its retention unaltered, and under Clause 8 of the Bill, practically every organization which now obtains benefit from the 1843 Act would in future qualify automatically for 50 per cent derating, and the local authority would have discretion to give up to complete exemption if it thought fit. As regards research associations, Mr. Brooke added, in reply to a question, that derating would turn entirely on whether an association could establish that it was a charity.

Mr. Brooke also said that the Pritchard Committee was clearly in some doubt about the position of the universities. While, as stated in the first schedule to the Bill, they were undoubtedly charities, they were also substantially financed by Exchequer grants, and, unlike other charities, many of them held a considerable if not a dominating position in the towns and cities in which they are established. Accordingly, it did not seem to the Government that a sufficient case existed for giving the universities a statutory 50 per cent exemption from local rates, although the Chancellor of the Exchequer was ready to give an

assurance that any additional rates falling on the universities in consequence would be taken into account in determining the amount of their recurrent Exchequer grants. He said also that this arrangement would not apply to the Oxford and Cambridge colleges, which as charitable foundations would receive the 50 per cent mandatory relief.

In the debate, Mr. C. M. Woodhouse challenged this discrimination between the universities and the Oxford and Cambridge colleges as contrary to the recommendation of the Pritchard Committee, although that Committee had explicitly recognized that these colleges stood in a different relation to the Exchequer from university institutions in general in that they received no financial aid directly from the University Grants Committee. Mr. Woodhouse doubted whether the distinction was valid or should be perpetuated, and pointing out that the finances of university and colleges were interlocked, observed that in its memorandum to the Pritchard Committee the Treasury had been disinclined to accept the obligation that Mr. Brooke now said the Exchequer would accept for the universities. He thought it perfectly reasonable that an increased burden on the universities should be met from the national Exchequer rather than from local funds, but that the same argument should apply to the colleges, and pointed out that in view of the decision in a test case brought last year to the Lands Tribunal by three of the colleges the effect of the present Bill would be to give the colleges double relief. A Government contribution, suggested by the colleges in their memorandum to the Pritchard Committee as the proper remedy, would avoid these rating anomalies, and Mr. Woodhouse urged the Minister to exercise his power of addition to the First Schedule and include at least the Oxford colleges.

In replying on behalf of the Government, the Parliamentary Secretary to the Ministry, Sir Keith Joseph, said that in representations before the Pritchard Committee the colleges had made it clear that they regarded the question of value as an entirely separate issue from that of rate relief. In general, the Government viewed the Oxford and Cambridge colleges as closer to educational establishments than grant-aided universities, but promised to study the point raised before the committee stage of the Bill. The question of scientific societies, and particularly the point raised by Lord Adrian in the House of Lords, was not mentioned in this debate.

The Medical Research Council of Canada

THE National Research Council of Canada has established a Medical Research Council with responsibility for all activities formerly conducted by the National Research Council's Division of Medical Research. The new Council will have virtually complete autonomy in its operations and full responsibility for policy concerning the support of medical research, but will function under the general administration of the National Research Council. The Medical Research Council has been set up as an interim measure pending the Government's future consideration of appropriate legislation. The eventual establishment of a completely independent Medical Research Council was implied in a statement in the Canadian Parliament last summer by the Hon. Gordon Churchill, chairman of the Canadian Privy Council Committee on Scientific and Industrial Research.

Officers and members of the new Medical Research Council are: *Chairman*, Prof. R. F. Farquharson, professor emeritus of medicine, University of Toronto, vice-president (medical), National Research Council; *Secretary*, Prof. J. Auer, professor of anatomy and associate dean, University of Ottawa; *Members*, Prof. L. B. Jaques, professor and head of the Department of Physiology and Pharmacology, University of Saskatchewan; Prof. R. W. Reed, professor and head of the Department of Bacteriology, McGill University; Prof. C. B. Stewart, dean of the Faculty of Medicine and head of the Department of Preventive Medicine, Dalhousie University; Prof. M. Brown, professor of medicine, Queen's University; Prof. M. Darrach, professor and head of the Department of Biochemistry, University of British Columbia; Prof. R. Rossiter, professor and head of the Department of Biochemistry, University of Western Ontario; Prof. J. Doupe, professor and head of the Departments of Physiology and Medical Research, University of Manitoba; Prof. A. L. Chute, professor and head of the Department of Paediatrics, University of Toronto; Prof. R. Gingras, assistant dean of medicine and head of the Department of Biochemistry, Laval University; Prof. W. C. MacKenzie, dean of the Faculty of Medicine and professor of surgery, University of Alberta; Prof. F. C. MacIntosh, professor and head of the Department of Physiology, McGill University; Prof. L. P. Bouthillier, professor and head of the Department of Biochemistry, University of Montreal; Prof. H. E. Taylor, professor and head of the Department of Pathology, University of British Columbia.

Jubilee Celebrations in Berlin

THE Humboldt University of Berlin celebrated its 150th Anniversary together with the Charité Hospital, the 250th Anniversary of which ran concurrently. Symposia, conferences, discussions and exhibitions were offered to participants by the various faculties, including those of Medicine, Philosophy, Mathematics, Physics, Politics, Economics, Pedagogy, and Jurisprudence. The Institute of Anglo-American Literature organized lectures and discussions simultaneously. The proceedings took place during November 6-20 and enabled each faculty to give its guests noteworthy entertainment from the operatic, theatrical and musical riches which the city possesses. University dignitaries, ministerial houses and student bodies opened their doors in a succession of receptions and discussions which encouraged the informal interchange of ideas and ideals. The Faculties of Philosophy and Medicine took three days to discuss together their understanding of humanism and medicine, representational thinking, cybernetics and its role in medicine, the concept of illness and, finally, the theory and practice of medicine. The physiology symposium, spread over three days, was devoted to an exhaustive, many-sided analysis of the red-blood cell structure and function. Energetics, cell stability, and biochemical interrelations received outstanding treatment by workers drawn from many countries.

Wildfowl Conservation Committee

SINCE 1954 the Nature Conservancy has held a regular series of informal meetings with leading wildfowling and wildfowl conservationists, including representatives of the Wildfowling Association of Great Britain and Ireland, the Wildfowl Trust and the

British Field Sports Society. Much experience has been gained as a result of these meetings in bringing together the interests of conservationists and wildfowlers and about the selection and management of wildfowl refuges, such as those already set up on the Humber, at Southport and at the Caerlaverock National Nature Reserve. Wildfowl refuges form a desirable and, in some conditions, an indispensable means of conserving and increasing wildfowl stocks, in which the wildfowlers are no less interested than the protectionists and scientists. It is now intended to develop out of this consultation and agreement a National System of Wildfowl Refuges which will in due course form the main British contribution to the projected international network of European refuges. North America has long since operated such a system with outstanding success. The Conservancy has decided in view of the importance of the work of this informal group that it should now be formally constituted as the Wildfowl Conservation Committee with the status of a special advisory committee of the Conservancy. Mr. E. M. Nicholson, director-general of the Nature Conservancy, will be chairman of the Committee, which will include members of the Wildfowlers' Association of Great Britain and Ireland, namely, Lieut-Comdr. J. W. Anderton, Mr. J. L. Hirst, Brig. G. D. Holmes, Colonel J. N. Vallance, Mr. E. L. Parish and Dr. G. W. Storey; the Wildfowl Trust, Mr. Peter Scott, Dr. G. V. T. Matthews, Mr. G. L. Atkinson-Willes and Mr. Hugh Boyd; the British Field Sports Society, Major J. G. Morrison, Brigadier A. H. Pepys and Sir Ralph Clarke; and the Nature Conservancy, Dr. J. Berry, Dr. E. B. Worthington and Mr. R. E. Boote. There are also two independent members of the Committee, namely, Colonel H. J. Cator and Major-Gen. C. B. Wainwright.

Country Life

AN interesting example of the fine work done by the Council for the Preservation of Rural Wales is described in its annual report for 1958-59 (Pp. 77+5 plates. London: Council for the Preservation of Rural Wales, 1960). In 1958, the late Lord Bledisloe, then president of the Gloucestershire branch of the Council for the Preservation of Rural England, offered to present a cup to be competed for annually for the best kept village in that county. Since then, many other competitions on a county basis have been held throughout England and Wales based on the Gloucestershire pattern. Some of these have been held under the auspices of various branches of these two councils, others under the auspices of other bodies such as women's institutes, county associations of parish councils, and rural community councils. In Wales, the competitions were inaugurated in Glamorgan through the award of the D. C. Jones Challenge Cup for the best kept Village in the Vale, under the joint sponsorship of the Council for the Preservation of Rural Wales, Glamorgan Branch, and the Barry Horse and Horticultural Society. Now there is a competition annually in most of the Welsh counties, and the entries are increasing every year. In the first year's competition, twenty-one villages entered and the prize was awarded to St. Nicholas, which was runner-up jointly with St. Fagans to St. Hilary last year. The report, available from the Secretary, Council for the Preservation of Rural Wales, 4 Hobart Place, London, S.W.1, contains full details of the many-sided activities of the Council in its work. The Council would welcome new members.

Archive for History of Exact Sciences

IN spite of the proliferation of scientific periodicals of all kinds, a warm welcome must be extended to the publication of a new journal, *Archive for History of Exact Sciences* (Vol. 1, No. 1. Pp. 106. Five numbers, individually priced, constitute a volume. D.M. 19.60. Berlin: Springer-Verlag, 1960). It should help in what has become almost an international duty, namely, to build those bridges possible between the domains of the sciences and the humanities. To do this is far from easy, but the need is a very real one. A study of the history of science is beneficial in both camps, always provided that it does not become merely a soft option; in other words, that the standards are set high. This, the new journal seems prepared to accept: it has a distinguished editorial board, and it will do well if it lives up to its dedication, "to uphold the tradition of P. Duhem and E. T. Whittaker". The first issue contains two papers—both dealing with important themes—one on rational mechanics in the Age of Reason, and the other on the beginnings of Euclid's axiomatic system. Contributions will be acceptable in the usual European languages, with the addition of Latin. To judge from the publisher's notice and the first of these articles, the English rendering leaves a good deal to be desired; the phrasing is a little clumsy and in one or two cases quite obscure. Improvement here should not be difficult, but it needs taking in hand at once, before this otherwise excellent production becomes suspect and its merits overlooked.

Leather Manufacture

THE inaugural lecture by Prof. A. G. Ward, following his appointment as professor of leather industries at the University of Leeds, was concerned with science and art in leather manufacture. Prof. Ward emphasized that, despite sixty years of intensive research, the making of leather still remains mainly an art and will continue to do so until its properties become amenable to measurement. At present there is little unanimity about what those properties are. In a brief historical review, Prof. Ward showed how much the improvement in the qualities of leather has been due to practical tanners who used methods analogous to scientific experiment but who lacked an accepted body of theoretical knowledge (Science and Art in Leather Manufacture: an Inaugural Lecture. Prof. A. G. Ward. Pp. i+20. Leeds: Leeds University Press, 1960. 2s. 6d.). Many efforts to provide the theoretical background to empirical facts have so far failed to provide an accepted and adequate view of leather-making processes. But the pace of change to-day makes it dangerous to the industry to assume that the art can develop fast enough to meet the challenge from industries based on science. Both the need of the industry and the state of the subject emphasize that an extension of basic science in this field is opportune. It is to be hoped that successful research can enable one more of the great craft industries of Britain to play its part in the modern world.

Some Water-mites from Seepage Water

COLLECTIONS by T. Gledhill from one locality yielded seven species of water-mites, each from a different family; four species are new to Britain and a fifth has previously been recorded from Ireland. The collections were made in seepage-water and are

outlined in the August issue of the *Journal of the Quekett Microscopical Club* (5, Ser. 4. No. 11. 1960). The locality is about 300 ft. above sea-level and situated on the eastern slopes of Claife Heights in the Lake District. The water appeared from under a large boulder, and made an area of wet woodland debris in some parts of which *Chrysosplenium oppositifolium* was growing. It was only when the surface debris was removed and a small hollow made that water would collect, and is the type of place which continental workers would call a helocrene. The species caught were: *A-Thienemannia schermeri*; *Hygrobatas norvegicus*; *Hydrovolzia placophora*; *Paniselus thienemanni*; *Pseudofeltaria scourfeldi*; *Bandakia concreta*; *Ljania bipapillata*. The first four were previously unknown in Britain, while *Paniselus thienemanni* is the only known species of its genus.

Heterotrophic Nutrition of *Chlorella*

IN studies of the heterotrophic nutrition of *Chlorella vulgaris* (Brannon No. 1 strain) cultured in darkness, D. J. Griffiths, C. L. Thresher and H. E. Street (*Ann. Bot.*, N.S., 24, 1; 1960) have tested the utilization, as carbon sources for growth and respiration, of a range of sugars, sugar alcohols, sugar phosphates, organic acids and monohydric alcohols. Considerably higher rates of growth and respiration were obtained with *d*-glucose than with any other substance tested. Ethanol (at 0.005 *M*) sustained both growth and respiration at c. 50 per cent of the level with glucose (0.028 *M* or higher). Evidence was obtained that the organism can become 'adapted' to utilize *d*-galactose and sucrose as effective carbon sources. Sustained growth was not obtained with any of the other substances tested. The glucose monophosphates, methanol and certain organic acids (oxalacetate, α -ketoglutarate, *cis*-aconitate, and pyruvate) clearly stimulated oxygen-uptake, but to a less extent than ethanol. The other substances tested were either inhibitory to respiration or inactive, or of very low activity as substrates. The growth in darkness and in liquid culture of *Chlorella* when supplied with *d*-glucose was insensitive to pH over the range 4.5-7.0, and was markedly enhanced by a high level of aeration. Gains in cellular dry weight ranging from 45 to 90 per cent of the weight of *d*-glucose disappearing from the culture medium were recorded in growth experiments; measurements of evolution of carbon dioxide in the Warburg apparatus indicated retention of up to two-thirds of the glucose-carbon in cell material.

Christmas Lectures for Young People

AMONG the lectures which are to be specially organized for young people during Christmas and the following weeks are: The one hundred and thirty-first course of six Christmas lectures, which is to be given by Dr. V. E. Cosslett on "Seeing the Very Small", at the Royal Institution on December 29, 31, January 3, 5, 7, 10, at 3 p.m. (Further information can be obtained from the Royal Institution.) A lecture on "Plastics and Textiles", to be given by Dr. H. A. Thomas in the Lecture Theatre of the Institution of Electrical Engineers, Savoy Place, London, W.C.2, on January 2, at 2.30 p.m. (Further information can be obtained from the Plastics Institute, 6 Mandeville Place, London, W.1.) A lecture on "Gyroscope and Pendulum—the Modern Travel Agents", to be given by R. J. Lees, head of

the Instrument and Photographic Department of the Royal Aircraft Establishment, in the Lecture Theatre, Royal Aeronautical Society, 4 Hamilton Place, London, W.1, on January 5, at 3 p.m. (Further information can be obtained from the Royal Aeronautical Society.)

Announcements

PROF. W. HUME-ROTHERY, Isaac Wolfson professor of metallurgy in the University of Oxford, has been elected an Honorary Member of the Institute of Metals. Major C. J. P. Ball, Dr. Maurice Cook and Lieut.-Colonel S. C. Guilan have been elected Fellows, in recognition of the services that they have rendered to the Institute. The total number of Honorary Members and Fellows are each restricted to twelve.

PROF. ALAN WOOD, professor of geology at the University College of Aberystwyth, has been awarded the Silver Medal of the Liverpool Geological Society in recognition of his contributions to geology.

PROF. V. F. WEISSKOPF has been appointed director-general of CERN, in succession to Dr. J. B. Adams, who will, next year, return to the United Kingdom as director of the Culham Laboratory for Plasma Physics Research. Prof. Weisskopf has been at the Physics Department, Massachusetts Institute of Technology, since 1945.

BRIGADIER H. E. HOPTHROW, assistant secretary to Imperial Chemical Industries, Ltd., has been elected secretary of the Royal Institution, in succession to the late Sir Harold Spencer Jones.

THE Television Society has invited Sir Harold Bishop, director of engineering of the British Broadcasting Corporation, to become president in succession to the late Sir George Barnes. Sir Harold Bishop has been with the Corporation since it was the British Broadcasting Company, Ltd., in 1923. He has been director of engineering since 1952.

BIOGRAPHICAL material relating to the late Academician A. F. Joffe is being collected by Madame Joffe. Any letters, photographs or personal recollections would be welcomed and should be sent to Madame Joffe at the Institute for Semiconductors, Kutuzova 10, Leningrad D-187, U.S.S.R.

A SYMPOSIUM on "Light Metal Industry in India" is to be held in the auditorium of the National Metallurgical Laboratory, Jamshedpur, during February 14-17, 1961. Further information can be obtained from the Director, National Metallurgical Laboratory, Jamshedpur-7.

THE fifth international conference on "Ionization Phenomena in Gases" is to be held at Munich during August 28-September 1, 1961. The conference is being organized by the Verband Deutscher Physikalischer Gesellschaften. Further information can be obtained from the Secretariat, Fifth International Conference on Ionization Phenomena in Gases, Oskar-von-Miller-Ring 18, Munich 1 (P.O. 463).

A SUPPLEMENT (1957-1959) to the Catalogue of Lewis's Medical, Scientific and Technical Lending Library has now been published (Pp. 306. To subscribers to the Library, 5s. net. London: H. K. Lewis and Co., Ltd., 1960. 10s. 6d. net). It is arranged alphabetically by authors, and is provided with a classified subject index which gives the names of authors of books listed in the Supplement which deal with the subjects classified.

CITY OF LIVERPOOL COLLEGE OF TECHNOLOGY

NEW SCIENCE BLOCK

SIR David Eccles, Minister of Education, opened the first instalment of the new City of Liverpool College of Technology on September 30, 1960. The new building provides accommodation for the Departments of Chemistry and Biology, Physics and Mathematics, and Pharmacy. The building (Fig. 1) has been designed and the work carried out under the direction of Dr. Ronald Bradbury, city architect and director of housing. It has been erected by Messrs. Henry Boot and Sons, Ltd., of Bootle, at a cost of £310,500. It is a concrete cased steel-framed structure, faced with rustic brickwork and artificial stone, purpose made bricks and coloured tiles forming patterned infilling panels between the floor-levels on the front elevation. The various floors, formed with precast concrete flooring units, have been finished generally with thermoplastic floor tiling, which in the case of the laboratories is acid resisting. Particular attention has been given to the design of the specialized laboratory furniture and fittings, which incorporate drawer and storage units and which are interchangeable, the whole of the units being finished in acid-resisting lacquer. The various services to the laboratories, which include hot and cold water, gas, electricity, compressed air, vacuum, steam, etc., are concealed in vertical and horizontal ducts, as well as in the suspended ceilings. The latter are formed with rectangular panels of asbestos board, and the patented

system of suspension enables each panel to be removed easily when access to the various services is desired. Each floor is served by an automatically electrically operated passenger and service lift, the latter enabling stores and materials to be transported conveniently from the main store on the ground floor to the materials issue stores on the upper floors. The laboratories have been designed, so far as possible, to house the most modern equipment and apparatus for teaching and research work in the departments concerned.

The Department of Chemistry and Biology occupies the ground and first floors, with certain advanced-research laboratories located on the second floor. The remainder of the second floor and the whole of the third floor accommodate the Department of Physics and Mathematics. The Department of Pharmacy is accommodated on the fourth floor, and a range of animal houses and ancillary rooms has been provided on the main roof. Each department has appropriate types of laboratories, rooms for departmental heads and staff, classrooms, lecture theatres and store rooms. The Department of Chemistry and Biology provides full professional training, postgraduate work and research for chemists and biologists, including courses leading to the external B.Sc. degree of the University of London, the diploma in technology in applied chemistry, and graduateship of the Royal Institute of Chemistry.

Fig. 1. New Science Block, City of Liverpool College of Technology

The Physical Chemistry, and Inorganic and Organic Laboratories are well equipped for teaching purposes. The Organic Research Laboratory includes apparatus specially designed by the staff for research work on gas adsorption, gas chromatography and electrochemistry. The equipment provided in the Instrumental Laboratory includes a recording polarograph, emission spectrograph, and an argon chromatograph. Some important and costly pieces of equipment have been installed in the special laboratories on the second floor. These include a Phillips E.M.100 electron microscope giving a resolution of 20-15 Å., and is being used in conjunction with an Edwards '12 E 6' coating unit for the examination of various inorganic gels and precipitates; a 'Raymax 60' X-ray generator, which is being used for X-ray powder photography, and a 'Unicam S.P.100' infra-red spectrometer. A suite of rooms is provided for research work in radiochemistry and radiobiology.

The Department of Pharmacy is responsible for the training of pharmacists who will eventually take their place in hospitals, manufacturing industry and retail work. Students attend the pharmaceutical chemist qualifying course. The Dispensary provides all the facilities required for modern dispensing. The Pharmaceutical Chemistry Laboratory is fully equipped to deal with standard analytical and preparative procedures with a particular bias to semi-micro techniques. Specialized apparatus includes a spectrophotometer, electrophoresis tank, a polarograph and Karl Fischer apparatus. The accommodation includes the Pharmacology and Physiology Laboratory and the Aseptic Laboratory, which enables students to work under conditions designed to exclude bacterial and fungal contamination from the air. The small-scale manufacturing laboratory permits many large-scale processes to be duplicated accurately. The research laboratories (situated on the second floor) are used for investigations covering pharmaceutical subjects, using modern techniques and apparatus.

The Department of Physics and Mathematics provides courses leading to the National Certificate in Applied Physics and to graduateship of the Institute of Physics, and examinations for external degrees of the University of London. The Department is also responsible for the mathematics and physics classes required by other departments for their certificate, diploma, and Diploma in Technology courses. Postgraduate courses are provided, and the Department has organized a number of research projects. The Physics Laboratories are well equipped and include spectrographic apparatus, high-vacuum equipment and an electron-microscope, the latter being a gift from an industrial concern. A large differential analyser has also been presented to the Department by an industrial firm. For the courses in mathematics and statistics there are various calculating machines, and an analogue computer is to be built.

Research projects undertaken by the Departments accommodated include the following: chromatography, electrochemistry, inorganic, polymer, sugar, surface and radiation chemistry, X-ray diffraction, electron microscopy; electron magnetic resonance, examination of cosmic dust, numerical analysis, and pharmaceutical subjects. A considerable amount of research work is carried out in collaboration with various industrial organizations. A number of members of staff have qualified for research grants from the Department of Scientific and Industrial Research.

Departments of the College offering professional courses award College associateships (A.C.T. (Liverpool)) to students who have satisfactorily completed courses approved for this purpose by the Board of Studies. Full-time and 'sandwich'-course students may be awarded an honours associateship, and, in exceptional cases, only students completing approved part-time courses. The College fellowship (F.C.T. (Liverpool)) is awarded for approved research work carried out in the College. S. A. J. PARSONS

CROYDON TECHNICAL COLLEGE

A NEW building, which was opened by H.M. the Queen on November 2, houses Croydon Technical College, Croydon College of Art and the Denning Hall. The premises, which occupy a site of nearly four acres, were projected before the War, but construction had to be deferred, and work was not begun until 1953. Although it has been dealt with in three stages under three separate contracts, building work has been going on continuously from 1953. The total cost of the building is about £1,450,000 and of the equipment housed in it about £375,000. The provision made will be enough for some 500 full-time and 10,000 part-time students. The architects are Messrs. Robert Atkinson and Partners, of Manchester Square, London, W.1.

Croydon Technical College traces its ancestry back to the establishment of classes, mainly in scientific subjects, in 1838, when the Croydon Literary and Scientific Institute was founded. But possibly a more important occasion was the foundation of a scheme for technical classes for artisans by the Rev. Oakley Coles, curate of the Croydon Parish

Church, in 1888. Two years later the Croydon Council decided to set up the Polytechnic, based on this modest beginning, and a new building was opened by the then Archbishop of Canterbury, Dr. E. W. Benson, in December 1891. As this was some years before the establishment of the local education authority, the Polytechnic was in fact the first educational institution to be maintained by the Council and is also the oldest technical institution to be maintained by any Council in the Greater London area. Control of the Polytechnic was transferred to the new Education Committee in 1903. The work of the College was extended continuously until, in 1929, H.M. Inspectors reported that the old building was inadequate for the services which the College was providing. Expansion of the work of the College has continued for the past thirty years, and recently the number of student enrolments has been increasing annually by at least 10 per cent. The expansion of the work since 1945 has in fact been greater than during the whole history of the College before that date. Enrolments for the present

session total 450 full-time and 8,000 part-time students.

The six-storey building consists of a centre block housing the administrative offices, refectory, laboratory and gymnasium—facilities shared by both the Technical College and College of Art—and four wings. The two west-wings and the majority of the south-east wing provide accommodation for the Technical College, while the north-east wing is exclusively for the College of Art. Noisy workshops used for mechanical engineering and building have been placed at the lower-ground floor-level, with special construction to keep noise and vibration from affecting the quieter rooms above, while a service road for these workshops runs under the whole length of the building. Lecture rooms, drawing offices and the lighter laboratories and practical rooms for science, electrical engineering, commerce, domestic science and food trades are grouped on the floors above. Lifts and the main staircases situated at the junctions of the two west wings and the two east wings communicate with all teaching floors; other staircases are provided at the extreme ends of the four wings. In the courtyard between the two east wings is situated the Denning Hall, which will seat approximately 750, and is a gift to the town by Mrs. Elizabeth Denning, in memory of her husband, who was Mayor of Croydon during 1913–16. This fine Hall may be used for the purposes of both Colleges and for other public purposes with an educational association.

Space will permit the detailed description of one Department of the College only, and the Department of Science has been chosen. This Department occupies almost all the fourth-storey accommodation of the two west wings and the centre block. The south-west wing provides laboratories for inorganic, organic and physical chemistry together with balance, store, preparation and dark rooms, a lecture theatre and classrooms. Physics is housed in the north-west wing, and is provided with four laboratories, a workshop, dark room, a lecture theatre, classrooms and stores. Also in this wing is the radioisotopes suite with the X-ray room adjacent. In the centre block on this floor are general science and biology labora-

tories together with further class-rooms. This accommodation serves the following courses of study:

	Students
Full-time	
General Certificate of Education	125
Part-time (day)	
General Certificate of Education	112
B.Sc. (General)	38
Ordinary National Cert. in applied physics	43
Higher National Cert. in applied physics	43
Graduateship of Institute of Physics	9
Ordinary National Cert. in chemistry	57
Higher National Cert. in chemistry	20
Evening	
General Certificate of Education	248
Horticulture	17

In addition, the Science Department acts as a 'service' department by undertaking the teaching of science required by other Departments of the College, for example, Bakery Science.

To provide for unknown expansion in the future, the building is designed on a unit grid with external planning and services as flexible as possible. In the chemistry section, for example, the larger class-rooms on the opposite side of the corridor to the existing laboratories are already provided with floor ducts and connexions to existing services to permit them being converted readily into extra laboratories. This means that, if additional building is needed, it will be principally class-room accommodation and that the dispersal of the various kinds of departmental practical rooms will be avoided.

Many new technical colleges cater for future expansion by building different blocks for different purposes, each of which has a 'growing point' for extensions. This method may be simpler than that described above; but the Croydon plan, with 'growing points' for class-room accommodation available on the inner sides of the existing east wings, is likely to provide the more compact building with shorter lines of communication for its users.

The integral nature of the building and the decision to place two independent Colleges under one roof are perhaps the most distinctive features of what the Queen referred to as "this imaginative experiment" in which young scientists, technicians, craftsmen and artists may "meet and exchange ideas with those trained in other fields of knowledge".

BIOLOGY OF SPACE TRAVEL

A SYMPOSIUM on the "Biology of Space Travel", organized by the Institute of Biology, was held during September 29–30 at the Royal Geographical Society, Kensington.

For the opening session the chair was taken by Sir Lindor Brown. The first paper was by Air-Commodore W. K. Stewart, of the Royal Air Force Institute of Aviation Medicine, Farnborough, who gave an account of recent work on the physiological effects of acceleration. A semi-recumbent posture would allow acceleration for several minutes at about eight times gravity without severe physiological disturbance, and the accelerations on take-off of rockets would be close to this figure. However, little is known about the effects of vibration and of emotional disturbance under such conditions, and in such high accelerations the astronaut would find it very difficult to carry out any movements other than movements of the eyes and of the supported hands. The

forces on re-entry would probably reach rather higher figures, in the region of ten times gravity, and provision would be needed for ensuring that the astronaut was correctly positioned in relation to the deceleration; if this were assured the forces would be tolerable for the short period expected. Wing-Commander T. C. D. Whiteside, also of the Royal Air Force Institute of Aviation Medicine, followed with a paper on the effects of the gravity-free state. Although no data are available for man for prolonged periods of weightlessness, it is probable that the physiological effects would not be severe. Eating would be easy, but fluids would have to be sucked from plastic containers. Locomotion would be easy in the dimensions of a small space-vehicle. However, it seems likely that muscular weakness would develop in a few days due to lack of exertion in a weightless environment, and this might reduce the tolerance to deceleration on re-entry. Regular exercises would

be needed to combat this problem. An unsuspected difficulty in low gravitational fields might occur if artificial gravity was produced by rotation of the space-vehicle itself, since even in large vehicles the Coriolis forces in the labyrinth of the ear produced on moving the head might give rise to disabling giddiness.

Lieut.-Colonel W. R. Turner, of the United States Air Force Aerospace Medical Division, Ohio, described the exacting series of physical and psychological tests employed in selecting candidates for the "man-into-space" projects such as "Project Mercury". The candidates were chosen from men with high basic qualifications, including a degree in engineering and 2,000 hr. of piloting jet aircraft. The examinations included exhaustive medical and psychological examinations and tests under conditions simulating those anticipated in space flight, such as high temperatures, acceleration and vibration. Other tests estimated noise-tolerance, patience with complicated and confusing machinery, and the ability to tolerate long periods of isolation. It was found that, given a normal physique, the motivation of the candidate played a surprisingly large part, and keen but level-headed men of about thirty-five years were the most successful at these tests.

For the second session the chair was taken by Sir Solly Zuckerman. Dr. D. McK. Kerslake read a paper by Flight-Lieutenant J. Billingham, of the Royal Air Force Institute of Aviation Medicine, on the maintenance of the thermal environment in space vehicles. When in orbit the temperature of the cabin would be maintained at a comfortable level by fairly simple air conditioning together with suitable insulation of the walls. On re-entry, however, the frictional heating of the exterior might cause severe over-heating of the interior, particularly if the time for descent was prolonged for any reason. Whether such over-heating will cause skin burns or heat stroke will depend largely on the rate of the rise in temperature. Both these dangers can be avoided by a special suit in which cold air is piped to the skin, and some impressive experiments were cited in which a man was well protected for several hours by this means in an environment at 125° C.

Mr. N. W. Pirie, of the Rothamsted Experimental Station, Harpenden, discussed the problem of the synthesis or re-cycling of oxygen, food and water on longer space flights. Water is unlikely to be a severe problem since most of the expired water vapour can be readily condensed and distillation of urine would allow the recovery of most of the remainder. The astronaut would require about 1 kgm. of oxygen a day, and the expired carbon dioxide would have to be absorbed: for short voyages potassium tetroxide would be suitable for this dual purpose. For longer voyages it has been suggested that algae such as *Chlorella* could be used to regenerate oxygen and foodstuffs by photosynthesis. There would be many technical problems in this. Outside the orbit of Mars the intensity of sunlight would fall to a level too low for effective photosynthesis: the algae would be very difficult to handle, maintain and process, and they would not in any event be suitable as the sole source of food. Complex chemical syntheses would require weighty and complex apparatus. An exciting possibility is that some way may be found of readily converting energy into essential biochemical intermediates, so that one could 'recharge' one's energy supplies in a manner analogous to recharging an electric accumulator.

Mr. S. W. F. Hanson, of Armour and Company, Ltd., London, read a paper on the supply of food to astronauts. He described recent progress in packaging food in a suitable form, and in particular the advantages for long journeys of dehydrated and pre-cooked foods, which can be prepared in wide variety; this is of great importance from the psychological point of view. He believed that at the most *Chlorella* would prove to be only an adjunct to the diet of astronauts, even if the technical problems of growing it were overcome. He showed a film which illustrated some of the problems of feeding under conditions of weightlessness.

On the morning of the second day of the symposium Sir Harrie Massey took the chair. Dr. P. Alexander, of the Chester Beatty Research Institute, London, read a paper on radiation in space and its effects on man. Most of the ionizing radiation in space consists of electrons and protons. The majority of the electrons will be stopped by the walls of the space-vehicle, though they will generate X-rays in this process which could penetrate the vehicle; in the inner of the two equatorial Van Allen radiation belts this secondary radiation might deliver a dose of about 5 rads/hr. to the astronaut. The protons, although more penetrating than electrons, would only deliver about 1 rad/hr. The radiation in the outer Van Allen belt would be less than that in the inner belt. In deep space the dose-rate would be small, probably about 10 rads per annum. In a short flight through the Van Allen belts and back the astronaut would receive a total of about 15-20 rads, which would be well below the permissible level in these special circumstances, and, by choosing a polar route, the radiation would be reduced considerably.

A paper on the psychological problems of solitude and confinement was read by Dr. R. Beech, of the Institute of Psychiatry, Maudsley Hospital, London. Dr. Beech reviewed thoroughly the published research on this topic, and concluded that very little reliable data were available. The tendency for sensory deprivation to cause abnormal mental behaviour, such as hallucinations, was now well recognized, but the degree to which this might occur in space flights was problematic, and little was known on the best ways to combat it. Dr. W. Grey Walter, of the Burden Neurological Institute, Bristol, in a communication entitled "The Human Brain in Space Time", described some recent work on the ability to learn under difficult and confusing conditions, and he emphasized the marked individual variations in the ease with which certain associations were recognized and learnt. He also raised the interesting question of the mental qualities which would be most desirable in astronauts, and noted that outstanding pioneers in many fields have frequently been decidedly eccentric individuals.

The chair in the final session was taken by Dr. A. S. Parkes, president of the Institute of Biology. Dr. P. H. A. Sneath, of the National Institute for Medical Research, London, discussed the dangers of contaminating the planets with terrestrial micro-organisms, or of contaminating the Earth with planetary organisms, should these exist. Recent work suggests that some soil bacteria may be able to multiply under the conditions found on Mars, and if we contaminate Mars with such bacteria the loss of scientific information would be enormous. The sterilization of a space rocket poses some very difficult problems, which urgently need further attention. It would be very dangerous to bring back to the Earth samples from other planets, because of the

risk that they might contain organisms which could prove dangerous to the ecology of the Earth, and it would be advisable first to carry out experiments on these in closed ecology chambers on manned satellites.

The last paper was by Dr. Harlow Shapley of the Harvard Observatory, who discussed the probable environment of other planets. He felt sure that there must be many planets in the universe which would be suitable for life as we know it on Earth (quite apart from the possibility of life in other forms) and it would seem inevitable that some form of life would have evolved on many of them. Whether we can ever communicate with such worlds was another matter. An important factor in the evolution of higher life may be the ozone layer of the Earth's atmosphere (itself due indirectly to the photosynthetic production of oxygen by primitive plants) since this layer protects terrestrial organisms from short-

wave ultra-violet rays. None of the other planets of our solar system appears to possess such an ozone layer.

In summing-up, Dr. Parkes discussed the possibility that astronauts might travel for most of their journey in a state of suspended animation, only to be revived when they reached their destination, and recent work on the freezing of whole animals shows that this is not a wholly fanciful suggestion. This also raises the question of whether man would have a useful part to play in the early stages of space travel, or whether it would be better to devise very elaborate machines to make the observations. The symposium had the excellent result of bringing together workers in many disciplines, and it showed that the remaining difficulties in short-range space flight were mainly engineering problems, while those affecting the astronaut himself would soon be largely solved.

INFLUENCE OF CLIMATE ON LIFE

ONE of the most obvious, and at the same time one of the most neglected, statements in the whole field of biology is that all life depends on its environment. Biologists and medical men of the past have made this the basis of much of their thinking, and engineers and architects have often built machines or houses to suit specific climates, but scientific journals still contain reports of biological experiments in which the experimental conditions were neither controlled nor recorded, and buildings or vehicles often fail to display any consideration for local climate. Even the impressive Unesco headquarters completed a few years ago in Paris are liable to cause heat exhaustion in people working there on sunny days, and it is well known that motor-cars are the hottest places to be found in many tropical countries.

At the other extreme, tables of comfortable environmental temperatures usually assume that simple mathematical expressions can be valid in biological processes, and ships ply through some of the climatically most pleasant seas of the world carrying with them the same constant artificial micro-climate which can be found in any office building in New York or London.

The International Society for Bioclimatology and Biometeorology held its second International Bioclimatological Congress recently in London with the avowed intention of improving knowledge about the influence of climate on life by bringing together people active in all parts of the world and in all branches of science whose work is related in some way to these problems. The success of the Congress was considerable, and its effects will probably be felt for some time to come. Some of the work helped to cross-fertilize or to dispel misconceptions by passing ideas and techniques between different specialties or different countries, but much new information of interest was also provided.

Symposia included one on life at high altitudes in which Prof. R. Margaria (University of Milan) related the problem of acclimatization to anoxia with space flying where less oxygen means less pressure which, in turn, means less weight. He also reported

the results of experiments which showed that the carotid body chemoreceptors of man were sensitive to oxygen, in any event during anoxia, which was of interest in view of occasional criticisms against conclusions made from such studies on anaesthetized animals. A paper by Prof. A. von Muralt and Dr. W. H. Weihe (University of Berne) reported experiments carried out on the Jungfrauoch at about 11,000 ft. and mean barometric pressures of about 500 mm. of mercury which showed that the threshold for various stimuli, such as taste, touch or tendon reflexes, was reduced at high altitudes but returned to normal if oxygen was breathed in. Prof. R. Schumacher and Dr. R. Schindler (Hamburg) reported on the 'high-altitude disease' observed at about 16,000 ft. in the Andes, where cattle developed heart failure and oedema but recovered quickly after a descent of only about 1,500 ft., a condition reproduced experimentally in rats and observed sometimes in man. It is difficult to escape the conclusion from this that the pressures to be chosen for long journeys into space will not be the lowest to which people at rest can become acclimatized but the lowest which will avoid heart failure and oedema.

In a symposium on life in the tropics, Prof. Alrick B. Hertzman (University of St. Louis) suggested, among other things, that correlations between the cardiac output and the skin blood-flow were purely coincidental, as there were situations when one was high and the other low, for example, when the skin is cooled after the whole body has been warmed. However, it could equally be argued that the correlations between these are part of a system integrating many variables, which usually works in a given way but in which no single correlation is immutably fixed, thus conforming to what might be predicted in any complex control system and making the relationship between cardiac output and skin blood-flow somewhat more predictable than a mere coincidence. Dr. H. Boyko (Israel) showed some impressive photographs to illustrate how a patch of desert could be turned in a very short time into a lush garden by applying sound principles of bioclimatology. Dr. J. C. D. Hutchinson (now in Parramatta, Aus-

tralia, but well remembered from his Cambridge and Edinburgh days) surveyed the problem of domestic cattle in the tropics, especially from the point of selective breeding, and he showed, among other things, how clipping the fur could increase the rate of growth in farm animals, simply by improving heat tolerance. Prof. W. Richards (Bangor) discussed tropical plants, and he quoted recent evidence from Ibadan and Cambridge that the rapid growth of these plants was related to the favourable growth of their new leaf. He also quoted some odd rhythms in equatorial plants, for example, one in Singapore which has a rhythm of 2 years and 8 months, or the Malayan pigeon orchid which flowers quite irregularly though pigeon orchids in any given area always flower on the same day.

Prof. C. P. Luck (Kampala, Uganda) described his studies on elephant, giraffe, rhinoceros and buffalo, which he hunts with cross-bows and succinyl-cholin-impregnated arrows, so that he can collect sweat, blood and urine, measure body temperatures, or even inoculate animals against diseases, without harm to the animals and, one was glad to hear, with safety to himself. Prof. E. B. Edney (Salisbury, Southern Rhodesia) showed that crabs took increasing amounts of oxygen and survived greater temperatures after acclimatization to heat than before, and that tsetse flies were able to evaporate water from their spiracles, thus avoiding over-heating while engaged in the hard work of sucking blood in close proximity to a warm animal.

There were many small sessions dealing with more specialized problems. Dr. T. R. A. Davis and Dr. R. J. T. Joy (U.S. Army Research Laboratories, Fort Knox) reported that animals and man exposed to cold for 2 hr. daily showed a reduction of shivering after 21-24 days, which was accompanied by an increase of heat production in the muscles without any electromyographic evidence of shivering. Prof. J. Grayson (Ibadan, Nigeria) produced evidence of similar, apparently purely chemical, heat regulation in the liver, which could also play a part in improved cold tolerance after acclimatization to cold. Related to these findings were those of Prof. H. Hensel and his associates of Marburg, Germany, that cooling of the hypothalamus in animals produced an increase of metabolism in the rest of the body within a few seconds, but more so at lower than at higher environmental temperatures. Taken together, these data probably mean that there may exist a form of true chemical heat regulation not related to shivering, which is probably controlled by the temperature of the hypothalamus, and which can be modified

either by thermal impulses from the skin or by a repetition or continuation of the cold stimulus.

Equally interesting was evidence, also from Prof. Hensel, that thermal receptors discharge at a constant level of activity during constant stimulation, so that in the absence of any environmental change the central nervous system receives a constant level of thermal information. In other words, thermal receptors would seem to become adapted extremely slowly or not at all. This fits in well with evidence from the London Hospital Medical College that the diminution of sensations and responses to repeated or continued stimuli which plays an important part in acclimatization is a result of a central nervous mechanism of habituation and not of any changes in the peripheral receptors.

Other discussions had a wide range, though some did not get beyond defining useful fields for further study. Among these was the problem of air pollution, which appears to be complicated by the fact that certain particles suspended in the air reinforce the action of others. Recognition of one or more potentially harmful substances in the air is therefore insufficient to assess air pollution, and predictions may have to be based on a better knowledge of synergistic actions of individual particles.

Difficulties of using scales of environmental comfort were stressed in a very active group on town planning under the chairmanship of Prof. J. K. Page (Sheffield). It appears that builders and engineers use at least four different comfort scales; but if one remembers the effects of habituation on thermal comfort it appears likely that many more comfort scales would be in use if more people had tried to compute such scales. Evidence was presented also that the provision of warmth is cheaper and easier in cold climates than the provision of cool air in hot places; but this may not always be so, as civilized communities have studied heating longer than cooling. Evaporating water, where it is available, from the roofs of buildings, as well as the use of solar energy to drive cooling compressors, might lead to simple and cheap ways of avoiding the overheating of buildings or vehicles in hot climates, and considerable improvements may be achieved by good design. Opinions were expressed suggesting that technology may soon remove the need for any physiological adjustments to changes of temperature, but by and large this Congress left the impression that we are still far from the days when uniformly clad people will live at a constant level of thermal acclimatization in one and the same environment anywhere on the Earth and outside it.

E. M. GLASER

COLONIAL DEVELOPMENT AND WELFARE

THE schemes made under the Colonial Development and Welfare Act in the period April 1, 1959, to March 31, 1960, which are detailed in the latest return, bring the total commitments, from April 1, 1946, under the Act to £221,023,632, of which £18,792,837 is for research schemes*. The totals for the year in question are £33,001,222 for

development and welfare and £2,370,261 for research schemes. Of this last, £1,009,974 is for agriculture, £560,600 for pesticides, £375,080 for medicine, £167,180 for locust control, £63,860 for fisheries, £57,289 for products research, £45,160 for tsetse fly and trypanosomiasis research, £41,697 for social science, and £7,796 for economic research.

Of the actual research schemes, £313,032 is for the Colonial Pesticides Research Unit, Arusha, Tanganyika, as well as a supplementary £57,139, 1960-

* Colonial Development and Welfare Act. Return of Schemes made and of Loans approved under the Colonial Development and Welfare Act in the Period from 1st April, 1959, to 31st March, 1960. Pp. 50. (London: H.M. Stationery Office, 1960.) 2s. 6d. net.

63; £181,000 for the agricultural research services, North Borneo, with a further £73,625 for the establishment of agricultural research stations; £124,755 for the Regional Research Centre at the Imperial College of Tropical Agriculture, Trinidad, and £47,459 for herbicides research at that College; £69,500 for the Anti-Locust Research Centre and its extra-mural activities, 1960-61; and £51,009 for the Colonial Pesticides Research Unit, Porton, 1960-63. £47,892 went to the East African Agriculture and Forestry Research Organization, £33,504 to the East African Trypanosomiasis Research Organization, and £33,283 to the East African Veterinary Research Organization; £38,250 was for trials with anti-typhoid vaccines; £55,506 to the Wellcome Institute for research on foot-and-mouth disease; £57,295 to the West African Rice Research Station, Rokupr, 1960-61; £77,911 for improvement and extension of agricultural facilities, Sarawak; and £33,350 for the study of dental leishmaniasis, British Honduras.

Other major research schemes include a supplementary £17,174 to the Fish Culture Research Institute, Malacca; £18,503 for research on spraying techniques and trace element deficiencies at Long Ashton; £42,968 for trachoma research in London and in The Gambia; £25,920 for the Desert Locust Survey; £16,607 for research into farm production costs, Kenya; and £39,650 for cereals research, Kenya, as well as £21,235 for research on coffee berry disease there, 1960-62; a supplementary £20,153 for cotton pest research, Nyasaland; £22,930 for the Joint Fisheries Development and Research Unit, Sierra Leone, 1960-62; a supplementary £19,489 for the Colonial Microbiological Research Institute,

Trinidad; and £15,126 for the East African Virus Research Institute; £27,882 was for the Colonial Pesticides Information Service, 1960-64; £16,500 for Overseas Research Fellowships, 1960-64; and £15,000 for Colonial Medical Research Studentships, 1960-64.

Development and welfare schemes of scientific interest include £17,232 to the Overseas Geological Surveys for age determination of rocks at the Geological Museum, University of Oxford; £25,930 for the Desert Locust Survey; grants totalling £376,633 to the Agricultural Department, Kenya, for the intensification of African agriculture, 1958-59; a supplementary £74,974 to Somaliland for scholarships and training abroad; £182,000 for the establishment of a Nature conservation area in the Ngorongoro Crater Highlands, Tanganyika; £68,500 for intensified control in Tanganyika of the Sudan dioch (grain-eating birds); and a supplementary £157,685 for forestry development, British Honduras. Educational grants include, besides £250,000 for a student hostel block, University College, Ibadan, Nigeria, a number of grants totalling more than £169,000 to the Nigerian College of Arts, Science and Technology; £210,000 and £233,250 for the second and third phase, respectively, of the expansion of general education in Lagos; £308,120 for building of schools in Northern Nigeria (with £341,500 for the development of health services); £368,000 to Fourah Bay College, Sierra Leone, for constructing and equipping two halls of residence, as well as £360,000 for the construction and equipment of Freetown Teacher Training College, Sierra Leone, and miscellaneous grants totalling more than £780,000 to the University College of the West Indies.

CONTROL OF INFECTIONS

DUE mainly to vaccination, fewer persons now suffer or die from such diseases as diphtheria, poliomyelitis and tuberculosis. If immunization programmes using the best available vaccines were more generally applied, the risk of infection from certain diseases could still further be reduced. Some of the problems raised by vaccination procedures are discussed in a recently published report of a European Technical Conference on the Control of Infectious Diseases through Vaccination Programmes*.

The report gives a broad picture of the legislation in force regarding vaccination in Europe. Compulsory vaccination varies considerably from one country to another; many use a mixed system in which some vaccinations are compulsory while others are not, and the general tendency is to substitute effective health education for compulsion by law. An important aspect is that of inspection and the recording of vaccinations, which makes it possible to obtain reliable data regarding their effectiveness. Generally the cost of vaccination programmes is borne by the health authorities; in some cases the cost has to be met by the patient himself, which may adversely affect the success of the campaign.

The report gives a brief account of the value and present state of the most important vaccinations. Although smallpox does not exist as an endemic disease in European countries, it was generally felt that it was still necessary to maintain a relatively high level of immunity in the population through continued vaccination programmes. It was agreed that BCG vaccination should be considered as part of the over-all tuberculosis control programme of any country. The report discusses the types of anti-polio vaccines used at present; inactivated virus vaccine and attenuated live virus vaccine, which have been successfully applied in the Soviet Union to more than twelve million persons. The use of triple vaccine against diphtheria, tetanus and pertussis is recommended, and consideration is given to the suitability and effectiveness of many other vaccines, such as those against influenza, typhoid, paratyphoid, tularemia, brucellosis, rabies, etc., as well as those used against quarantinable diseases (yellow fever, typhus and cholera).

After dealing with the risks and techniques of different vaccinations, the report discusses the importance they may have in the control of infectious diseases. It finally suggests models for programmes which, in the opinion of the conference, might be adopted in the various countries according to the degree of development of their health services and their own particular problems.

OPTICAL IMAGE ASSESSMENT

By DR. N. S. KAPANY

Optics Section, Physics Division, Armour Research Foundation,
Chicago 16, Illinois

IN recent years considerable attention has been devoted to developing methods for assessing optical image quality. A realistic criterion for the performance of optical systems has long been sought, and the advent of communication theory in optics has brought forth the concept of frequency response¹⁻⁴. The relative merits of conventional testing methods such as the star test, the square wave or bar test chart, edge response, energy density in the point image and the like have been adequately discussed. However, it is not widely recognized that for incoherent illumination all these criteria are simply interrelated and derivable from the basic point spread function of the optical system.

The need to assess the image quality of a lens system arises, first at the lens design stage, when the designer is forced to make compromises in order to balance the residual aberrations in the optical system, and secondly, when the lens is at the construction and assembly stage. The lens designer would like to estimate the information transfer characteristic of the system under its true operational conditions. Here the effects of aberrations, diffraction, contrast of the object domain, air turbulence and scattering, emulsion and development conditions and even mechanical vibrations need to be accounted for. On the other hand, the manufacturer and user of lens systems is interested in measuring the lens performance according to some meaningful criteria after it has been constructed. This article describes two methods for assessing lenses both at their design stage and after construction. A method has been devised which enables images of pictorial objects to be synthesized from data on the lens design and thus enables the lens designer to evaluate realistically the influence on the image of various image-degrading parameters. This system is expected to evolve into an accessory to an electronic computer. Also, an electro-optical bench has been constructed which is capable of presenting simultaneously the frequency response and phase curves of a lens system on a cathode ray oscilloscope, thus allowing measurement of lens performance at various field angles and focal positions in a relatively short time.

High-Speed Image Synthesizer

A method for convoluting the images of a pictorial test object from the lens design data has been described before⁵. The convolution integral can be written in two dimensions as:

$$h(x,y) = \iint_{-\infty}^{+\infty} a(x - \eta, y - \xi) f(\eta, \xi) d\eta d\xi \quad (1)$$

where the function a is the point spread function of the optical system, $f(\eta, \xi)$ is the object intensity function, and $h(x,y)$ is the image intensity function. One must assume incoherent illumination for the

object to allow superposition of the point intensity functions. The spot diagram is a close representation of $a(x,y)$ for optical systems not limited by diffraction and the analysis is valid over regions of the image plane where the aberration function remains constant.

In order to synthesize the optical images of various types of test objects, the intensity distribution function in the point image in the form of a spot diagram (bright spots on a dark background) has been used to illuminate the test object plane (Fig. 1). The convoluted image of the two-dimensional test object is received on an image plane in the form of a shadow of the test object. It is obviously desirable that the test object should not give rise to scattering, therefore test objects on thin emulsions have been used. The distances d and d' , and the relative sizes of the object, image and the point spread function simulate the appropriate conjugate relationship and the magnitude of the aberrations under true operating conditions.

Fig. 1. Optical arrangement of the image synthesizer

The magnification of the test object at the image plane is given by:

$$M_{(\text{object})} = \frac{d + d'}{d} \quad (2)$$

and the magnification of the point spread function is given by $M_{sd} = d'/d$. If a periodic line test object is used, the resolution is given by:

$R = (\text{test object scale}) (\text{spot diagram scale})$

$$\frac{M_{sd}}{1 + M_{sd}} \quad (3)$$

This system has been used for measuring image quality in the presence of various types of aberrations using periodic as well as pictorial test objects. Fig. 2a shows the theoretical and synthesized intensity gradient in the image of an edge for an $f/2.8$, 50 mm. photographic objective at $23^\circ 50'$ obliquity. Fig. 2c shows the square-wave response for the same lens in the sagittal and tangential directions as measured on the image synthesizer using the calculated spot diagram of the lens system. The pictorial images convoluted by this method have proved to be almost

indistinguishable from actual images produced by the lens built according to the same design. It is also possible to take account of such factors as diffraction, air turbulence and mechanical vibrations by using the point spread function in the presence of these image-degrading parameters. Fig. 2b shows the theoretical and experimental edge intensity gradient for a perfect lens as produced on the image synthesizer by approximating the intensity distribution in various rings of the Airy disk with areas of varying spot density.

Having established the performance of the image synthesizing technique and its ability to simulate not only the geometrical aberrations but also other complex phenomena, its application as an accessory to the electronic computer in assisting the lens designer becomes obvious. An approach that seems to offer much promise is the generation of the spot diagram upon the fluorescent screen of a cathode ray tube, the tube screen replacing the photographic plate in the image synthesizer. Thus, the co-ordinates of the spots representing the energy density in the point image can be calculated on an electronic computer, stored digitally either on magnetic tape or paper tape (Fig. 3a), and then displayed as successive bright spots on a cathode ray oscilloscope. Basically, the spot pattern is generated automatically by passing the tape through a digital-to-voltage converter using the output voltage from the latter to deflect the electron beam in two orthogonal co-ordinates. In general, it is found that of the order of 300-400 spots render a faithful synthesis of the image. Fig. 3b shows the photograph of spot representation of computed data on a cathode ray oscilloscope. As indicated in Fig. 1, this cathode ray oscilloscope is

Fig. 2. Image synthesis data: (a) theoretical and synthesized edge response of an $F/2.8$, 50 mm. lens at $23^\circ 50'$ field angle; (b) theoretical and synthesized edge response for a perfect lens, using Airy disk point spread function; (c) square wave response for the same lens position (as in Fig. 2a) measured on the image synthesizer

Fig. 3. High-speed image synthesis: (a) block diagram of the arrangement for the computation of the point spread function and the cathode ray tube display unit; (b) a spot diagram displayed on a cathode ray tube

then followed by a simple device consisting of a test object holder and a viewing screen or a photographic plate with variable intermediate distances d and d' . This system is thus used for high-speed image synthesis of optical systems while the optical system is still at the design stage.

Measurement of Frequency Response and Phase Shift

In order to measure the spatial frequency response and the phase shift introduced by optical systems after construction, an electro-optical lens bench has been designed. It is well known⁶ that the unidirectional spatial frequency response of an optical system is given by the Fourier transform of its line spread function, that is:

$$F(\omega) = \int_{-\infty}^{+\infty} a(x,y) e^{-2\pi i \omega x} dx dy \quad (4)$$

where $F(\omega)$ is the response for the spatial frequency (ω) and $a(x,y)$ is the point spread function of the optical system. Here, it is assumed that the point spread function does not vary over the slit-length. Furthermore, for incoherent illumination the simple unidirectional integration of the point spread function yields the line spread function.

Fig. 4. Illustrating the lens bench for measurement of frequency response and phase of lens system

The principle of this lens bench consists of imaging the line spread function of the lens under test on a rotating glass drum with variable frequency sine wave test objects mounted around it. A photomultiplier receives all the flux, and the contrast in the received signal is a direct measure of the frequency response of the lens. Furthermore, a comparison of this signal with another reference signal yields the phase shift. Both the frequency response and phase shift are presented on a dual beam display scope.

The optical system of the lens bench is illustrated in Fig. 4. A fine slit is placed at the focal plane of a collimator lens, and the lens under test is placed on a nodal slide. The line image formed by the lens under test is imaged at a magnification on the rotating glass drum using a well-corrected microscope objective. The rotating glass drum has mounted around its periphery variable frequency sine wave test objects⁷ consisting of 13 frequencies varying in steps of $\sqrt{2}$ and having 24 cycles of each frequency. A stationary photomultiplier placed in the rotating drum receives the signal when different frequencies are presented to the line spread function. The contrast of the received signal, given by the following expression, is a direct measure of the response for that frequency:

$$F(\omega) = \frac{I(\omega)_{\max.} - I(\omega)_{\min.}}{I(\omega)_{\max.} + I(\omega)_{\min.}} \quad (5)$$

where $I(\omega)_{\max.}$ and $I(\omega)_{\min.}$ are the magnitudes of the signal for a given frequency ω at the maxima and minima, respectively.

In order to present the frequency response curve on an oscilloscope, the signal from the photomultiplier is amplified linearly, half-wave rectified and applied to an integrator. Using a logarithmic potentiometer geared to the shaft of the rotating glass drum the integrator output is made proportional to the input. This output is gated to a clamp circuit which displays the magnitude of $F(\omega)$ on a cathode ray

oscilloscope. Fig. 5a shows the frequency response of an $F/6.8$, 125 mm. lens system at a 5° field angle with defect of focus, presented on an oscilloscope. The phase shift and spurious resolution are observable at higher frequencies.

The optical system devised to measure the phase change is also shown in Fig. 4. A reference slit is imaged on another portion of the sine wave test object using a highly corrected lens system and the signal is received by another photomultiplier. It is, of course, necessary that the reference slit and the line spread function of the lens under test be in good alignment. The comparison of signals from the two photomultipliers, with the use of appropriate electronics, yields the phase information simultaneously with the frequency response. Fig. 5b shows the phase change introduced by the $F/6.8$, 125 mm. lens system at a 5° field angle and with a defect of focus, presented on an oscilloscope.

Fig. 5. Cathode ray tube display of frequency response (a) and phase (b) curves for an $F/6.8$, 125 mm. lens system at 5° field angle with defect of focus

Conclusions

The two techniques described in this article seem to hold considerable promise for optical image assessment both at the lens design stage and after construction, and further work using these methods will be reported elsewhere. The high-speed image synthesizer is useful for evaluating realistically the influence of aberrations, diffraction, atmospheric turbulence and film characteristics, etc., on image quality without having to construct the lens system. Its uniqueness lies in the fact that it is capable of synthesizing images of pictorial test objects as well as conventional test objects. Therefore it can be used to evaluate the influence of psycho-physical effects on recognition and detection. A detailed programme incorporating the image synthesizer with a Univac 1105 computer is in progress. As a research tool the image synthesizer is capable of synthesizing images formed by other electro-optical systems such as cathode-ray tube and image intensifiers. Its application to the evaluation of X-ray image-forming systems and high-energy radiographic systems is at present being studied.

An interesting extension of the image synthesizer technique would achieve automatic lens design based on a most meaningful test method. Accordingly, use would be made of a correlation device that compares

the synthesized picture with a standard and feeds back an error signal into the computer (Fig. 3a). Thus the lens design can be continuously tested on the basis of its 'picture quality', and appropriate changes in the design be made automatically until the correlation function reaches a desired value.

The electro-optical lens bench is particularly valuable for investigating the influence of aberrations and diffraction on spatial frequency response and phase shift of lens systems. Since both curves are presented on the oscilloscope simultaneously, the change introduced at various focal positions and field angles can be studied in much detail. It seems to offer promise as a routine lens bench for lens assembly and evaluation work.

THE ACTION OF NITROUS ACID ON ALIPHATIC AMINES

By DR. A. T. AUSTIN

Organic Chemistry Department, The University, Leeds 2

ALTHOUGH T. W. J. Taylor in 1928¹ indicated the correct experimental conditions for carrying out the reaction of aliphatic amines with nitrous acid, the essential items in these conditions appear to have been overlooked by other workers who have used other conditions and, not surprisingly, have obtained little or no reaction. As part of a study of the mechanism of deamination by nitrous acid of aliphatic primary amines², an investigation of the products formed in the reaction of methylamine with nitrous acid was undertaken; this has not been reported before, because it in turn led to a study of diazotization, which, as the more convenient reaction for detailed kinetic treatment, became for a time the leading sector of attack on the problem of deamination mechanism in general³.

Taylor described the kinetics of the reaction between methylamine and nitrous acid¹, but so many incorrect statements, most of them in text-books, have been made about the products, that a new account of the matter seems desirable, though it was actually investigated some years ago⁴ and in a broader context. There was little doubt that methyl alcohol could be obtained from the reaction of methylamine with nitrous acid, as this had been shown by Linnemann⁵, who passed the gas evolved in the decomposition of faintly acidified solutions of methylamine nitrite through water and, on fractionation of this, had obtained the alcohol in good yield (50 per cent). The reaction was next investigated by Whitmore and Thorpe⁶, who were apparently unaware of Taylor's fundamental investigation, and, using quite unsatisfactory conditions, these workers were unable to obtain any methyl alcohol. In view of the

wide acceptance given to these negative findings, the following observations on the products that are obtainable in the methylamine-nitrous acid reaction are recorded.

The conditions used were those indicated by Taylor's work as being essential for reaction to take place, namely, a solution of the amine containing nitrous acid but—and this is important—no excess of mineral acid. As solutions of nitrous acid are unstable and evolve oxides of nitrogen at concentrations greater than 0.05 M, this acid was generated slowly *in situ* during the reaction by gradually adding mineral acid to the amine solution containing dissolved sodium nitrite. In a typical experiment, the methylamine hydrochloride (0.5 mole) was dissolved in water (550 c.c.) together with sodium nitrite (1.5 moles). Sulphuric acid (2 N, 0.4–0.6 equiv.) was then run in slowly beneath the surface of the solution. A brisk and steady evolution of gas ensued and the reaction proceeded readily at room temperature until less than 1 per cent of the amine remained. The evolved gas was passed through a container immersed in solid carbon dioxide/acetone mixture and then through a bubbler containing potassium permanganate (to remove oxides of nitrogen from decomposition of the nitrous acid) before being collected in a gas receiver. The products of the reaction in (a) the reaction vessel (b) the low-temperature trap and (c) the gas-holder were then investigated.

Distillation of the pale yellowish-green reaction solution in (a) caused the colour to darken to yellowish-brown, which then became opaque-green and much gas was evolved, part of which was carbon dioxide. The colour of the solution then became less intense

and finally pale yellow. A pronounced odour of bitter almonds was observed during the distillation, and this later changed to an ammoniacal odour. These colour changes and odours were shown to be caused by methylnitrolic acid that had been formed in the reaction. Fractionation of the distillate gave, at 64–85°, a two-phase liquid, the upper layer of which was shown to be aqueous methyl alcohol and the lower layer was shown to be mainly nitromethane.

The pale yellow liquid collected in the low-temperature trap (b) was shown to consist of a mixture of methyl nitrite (pale yellow, b.p. -18.5°) and methyl chloride (colourless, b.p. -24°). If methylamine hydrobromide was used in the reaction, then methyl bromide (colourless, b.p. 4.6°) was collected in the trap instead of the chloride.

The volume of gas obtained from the reaction at room temperature was slightly greater (3 per cent) than that expected from the reaction:

The gas was shown to be nitrogen contaminated by a small amount of carbon dioxide.

Table 1. PRODUCTS FORMED WHEN METHYLAMINE HYDROCHLORIDE (0.5 MOLES) + SODIUM NITRITE (1.5 MOLES) IN WATER (550 C.C.) WAS SLOWLY ACIDIFIED WITH 2*N* SULPHURIC ACID (0.4–0.6 EQUIV.). ROOM TEMPERATURE

	Per cent
Methyl alcohol	6–25
Methyl nitrite	45–35
Methyl chloride	13
Nitromethane	6
Methylnitrolic acid	10–12
Evolved gas (nitrogen + carbon dioxide)	103 'theoretical'

These findings may be summarized:

(1) Methylamine readily reacts with solutions containing nitrous acid. *Methyl alcohol* is formed.

(2) *Methyl nitrite* is, however, the major product. This escapes from the reaction vessel owing to its volatility (b.p. -18.5°), and this escape is facilitated by the nitrogen evolved during the reaction. (Identical behaviour is observed in the reaction of ethylamine with nitrous acid and the major product, ethyl nitrite (b.p. 17.4°), condenses in the low-temperature trap.) The methyl nitrite is probably formed by two processes: (a) the direct and rapid esterification of the methyl alcohol by the aqueous nitrous acid; and (b) interaction of the methyl carbonium ion at the oxygen end of the ambivalent nitrite ion. The ratio *a/b* is not known, but a considerable proportion of the methyl nitrite must be formed via the esterification route since, for a given concentration of sodium nitrite, the amount of methyl nitrite collected in the low-temperature trap was greater the greater the volume of acid added during the reaction. There was a corresponding diminution in the amount of methyl alcohol that could then be isolated from the reaction vessel. This correlation is in-

dicated in Table 1 by the ranges given for the first two items, which should be read together, that is, a low yield of methyl alcohol corresponds to a high yield of methyl nitrite and vice versa.

(3) *Methyl chloride (or bromide)* is formed in the presence of chloride (or bromide). It was shown that under the conditions of the reaction, the methyl halide was not formed by esterification of the methyl alcohol by the acid halide. These compounds must therefore be formed as direct reaction products and not arise from secondary reactions.

(4) *Nitromethane* is formed in appreciable amount, and its formation is consistent with the formation of the methyl halides. It was shown by experiment that the nitromethane was not formed by re-arrangement of any of the methyl nitrite, nor was it formed in the direct esterification of the methyl alcohol by the nitrous acid.

(5) *Methylnitrolic acid* is formed. Experiments confirmed that part of the nitromethane, formed directly in the reaction, had reacted with nitrous acid to give the nitrolic acid in a secondary reaction:

This acid is unstable and decomposes via well-established reactions and accounts for the colour changes and odours (hydrogen cyanide, ammonia) observed when the reaction residues were heated. It was also shown that the amount of decomposition undergone at room temperature accounts for the slight excess (3 per cent nitrogen and carbon dioxide) of gas collected during the amine-nitrous acid reaction.

The multiplicity of products formed in the above reaction is rationally explained if one assumes that the electron-deficient entity,

is formed—a suggestion originally put forward by Whitmore⁷ for this type of reaction. The methyl-carbonium ion could interact with a water molecule

giving CH_3OH_2^+ , which, by loss of a proton to the solvent, would give methyl alcohol. It could unite directly with Cl^- or Br^- giving methyl chloride or bromide respectively. With the ambivalent nitrite ion, a considerable amount of interaction occurs at the N atom to give nitromethane. Some attack probably occurs at the O atom to give methyl nitrite directly. Although no secondary amine derivative was isolated from the reaction mixture, such compounds could arise by the CH_3^+ interacting with some of the unchanged amine, and the formation of secondary amine products has definitely been established by others in this type of reaction⁹. There is also the possibility of formation of ether. This could result from the reaction of the CH_3^+ with the alcohol formed in the reaction. This is not likely to occur to any appreciable extent in the reaction of methylamine, for the alcohol is swept out of the system as the very volatile nitrite ester. Of course, if an alcohol is used as the solvent for the reaction, it would be expected that the ether would then be the principal product. These reactions may be depicted as in scheme III.

With higher amines yet other reactions are possible for the carbonium ion. Proton loss can result in the formation of olefins and hydrogen, or alkyl groups, from other parts of the ion may migrate to the electron-deficient centre and in so doing create a fresh centre of electron-deficiency at the site vacated. The reactions noted above may then occur at the new centre of electron-deficiency.

The steps leading to the carbonium ion have also been established. Taylor's kinetic findings were confirmed, and the investigations led logically into the aromatic field³. Although Piria¹⁰ discovered the 'amine-nitrous acid reaction' by noting the effect of dissolved oxides of nitrogen and assumed that nitrous acid was the effective reagent (thereby setting the pattern of thought for a hundred years) it has now been shown that molecular nitrous acid, as such, is not a participant in the initial interaction with the amine. The squared-term for the nitrous acid in Taylor's kinetic expression has been shown to stand for N_2O_3 ($\alpha[\text{HNO}_2]^2$), and this as the effective nitrosating entity, originally suggested by Hammett¹⁰, has been placed on adequate experimental foundation together with NOCl , NOBr and NOI . The initial,

and rate-determining, step involves an electrophilic attack by N_2O_3 , NOCl , etc., on the free amine giving a N-nitrosoalkylammonium cation. The inhibiting effect of free mineral acid on the aliphatic amine-nitrous acid reaction is thus readily seen. These amines are so much more basic than their aromatic counterparts that any appreciable protonic concentration will cause the amount of free amine to diminish to vanishing point. Once the N-nitrosation has occurred, the base-weakening effect of the nitroso-group permits ready deprotonation of the nitrosoalkylammonium cation and the primary nitrosoamine then formed undergoes ready tautomeric shift to the diazo-hydroxide. This rapidly ionizes to the diazonium cation which, in the absence of resonance stabilization of aromatic groups, rapidly loses nitrogen giving the electron-deficient carbonium ion. The carbonium ion then undergoes the reactions already noted.

(where $\text{X} = \text{NO}_2, \text{Cl}, \text{Br}, \text{I}$).

(IV)

* If the original amine was tertiary the nitroso-alkyl ammonium cation could lose an alkyl group giving rise to a N-nitroso-secondary amine.

† If the original amine was a secondary amine the reaction would stop at this stage and the secondary nitrosamine can be isolated.

CORRELATION OF BIOLOGICAL ACTIVITY AND THE ELECTRON SPIN RESONANCE SIGNAL STRENGTH FROM GUINEA PIG ADRENALS

By FRANK K. TRUBY* and DR. JOSEPH W. GOLDZIEHER

Physics Department, Southwest Research Institute, and the Department of Endocrinology, Southwest Foundation for Research and Education, San Antonio, Texas

IN a previous communication¹ an improved low-temperature technique for the study of free radicals in biological materials was described. This method has now been used to study the relation between electron spin resonance intensities and the level of functional activity in mammalian tissue.

Adrenal glands from large adult male guinea pigs were used. Highly active adrenocortical tissue was

* Present address: Sandia Corporation, Albuquerque, New Mexico.

produced by daily injections of 5 clinical units of gel-adrenocorticotrophic hormone, followed by a single 5-unit injection of aqueous adrenocorticotrophic hormone 2 hr. before excision of the adrenals. High rates of steroidogenesis and adrenal glutathione turnover² are known to occur under these conditions. Hypofunctional glands were produced by suppression of endogenous secretion of adrenocorticotrophic hormone. For this purpose animals were given

4 mgm. hydrocortisone phosphate by injection daily for five days, followed by a sixth injection of the same amount 2 hr. before being killed. These animals, as well as equal numbers of untreated controls, were killed by decapitation and the adrenals excised as rapidly as possible. Adrenals from 2-3 animals (together with a small amount of isotonic saline to displace trapped air bubbles) were placed in borosilicate glass sample holders of 10 mm. diameter and immersed at once in liquid nitrogen. The weight of tissue plus saline in these samples averaged 1.7 gm. Electron spin resonance measurements were carried out at -180°C . in a conventional x -band transmission type spectrometer². The instrument was calibrated before and after each determination, using a secondary standard of coal dispersed in anhydrous dextrose. The resonance absorption had a g value close to that for free electrons ($g = 2.0023$). The signal intensity from each sample was adjusted to account for minor changes in cavity Q which occurred from sample to sample. Electron spin resonance runs were also made on sample tubes containing only the frozen saline solution. These measurements showed that essentially none of the resonance absorption obtained from tissue samples could be attributed to the sample tubes or saline solution. As the line-width and shapes for the resonance absorption signals were essentially identical for all samples, the relative electron spin resonance signal strength and thus the relative unpaired electron content could be determined by measuring the peak-to-peak height of the normal electron spin resonance derivative curves. Though no attempt was made to determine the absolute number of paramagnetic species present per gram of sample, the electron spin resonance signal strength obtained for a given amount of tissue was roughly one-fifth of that obtained from freeze-dried rat liver, which contained the order of 10^{-8} mole of free electron spin per gram wet tissue¹.

Following electron spin resonance measurement, the non-protein sulphhydryl concentration of a number of the samples was determined by a method described elsewhere³.

Table 1 summarizes the results obtained in five sets of experiments. The intensity of the electron spin resonance signal in the control adrenals varied from 15.1 to 60.1 with a mean value of 31.8. The values of the adrenocorticotrophic hormone-stimulated adrenals ranged from 15.5 to 30.4 with a mean value of 24.2. Statistical analysis shows that this difference has a

t -value of 2.72 with 12 degrees of freedom, which is significant ($P = 0.018$). One may also inspect these results on a non-quantitative basis, that is, that 7 out of 7 deviations (control minus adrenocorticotrophic hormone) are positive. On the basis of the null hypothesis, the probability of such a result occurring by chance is 0.016. The comparison of the electron spin resonance signal strength of the cortisone suppressed adrenals with the control adrenals is less revealing. The values for the cortisone-treated adrenals ranged from 20.9 to 39.4 with a mean value of 32.5. The probability of 4 out of 5 deviations being positive is 0.06. Thus it is reasonable to conclude that the control and adrenocorticotrophic hormone adrenals differ significantly, while no conclusion can be drawn about the suppressed adrenals.

It was of interest to compare these changes to the alterations in adrenal sulphhydryl concentration and turnover at the various levels of adrenocortical activity. It has been shown in rats⁴ that acute stimulation of the adrenal cortex causes a marked, transient increase in sulphhydryl concentration and turnover. Inactivation of the adrenals (by hypophysectomy) causes no change in the sulphhydryl concentration but some diminution of the turnover rate. Since some stable organic free radicals, as in the case of α, α diphenyl β -picrylhydrazyl⁵, may be expected to react with available sulphhydryl groups, one may well wonder whether or not the decrease in free radicals (and thus the electron spin resonance signal level) in stimulated adrenal tissue is not correlated with the known rise in glutathione. For this reason, adrenal non-protein sulphhydryl determinations were carried out in experiments 4 and 5. Unfortunately, the individual variations in SH concentration were large, greatly exceeding those observed in homogeneous rat populations. This variation (and possibly that in electron spin resonance signal intensity as well) may be related to the fact that the largest and therefore oldest animals available were used, to provide the maximum amount of adrenal tissue. This variance precluded the possibility of demonstrating SH changes such as are known to occur in rat adrenals.

There are many possible interpretations of these data other than a potential relationship of the electron spin resonance changes to sulphhydryl alterations. Other reducing agents such as ascorbic acid could act in the same manner as SH groups. However, under the conditions of the experiment the tissue concentration of ascorbic acid is sharply reduced rather than increased as is glutathione. It may be noted that our electron spin resonance findings are at variance with those of Commoner *et al.*⁴. However, these authors based their conclusions on a comparison of different tissues rather than on a study of the same tissue at different levels of activity, which we believe would be a far more valid criterion. Moreover, the high levels of electron spin resonance signal intensity found by Commoner in lyophilized tissues may well have been due to sorbed molecular oxygen⁶. The possibility that our tissue electron spin resonance signals were in part due to paramagnetic ions is recognized, and much work needs to be done to determine to what extent such ions contribute to the observed electron spin resonance signal. However, the work of Heggen and Strock⁷ shows that for rat liver tissue the content of paramagnetic ions having a g value close to 2.00 can account only in part for the electron spin resonance signal intensities observed¹.

Table 1

Exp. No.	Control		ACTH-stimulated		Cortisone-suppressed	
	ESR signal intensity	SH conc. μ /100 mgm.	ESR signal intensity	SH conc. μ /100 mgm.	ESR signal intensity	SH conc. μ /100 mgm.
1	85.7		23.7			
	60.1		15.5			
2	19.4				39.4	
	15.1				34.3	
	26.9					
3	37.5		28.1			
	31.0		30.4			
	31.0		27.2			
4	31.6	11.5	20.1	15.7	32.7	11.8
5	28.5	23.6	24.3	30.8	35.1	11.6
	33.0	16.6			20.9	15.8
Mean	31.8		24.2		32.5	

ESR, electron spin resonance; ACTH, adrenocorticotrophic hormone

Whether or not the paramagnetic ion content of guinea pig adrenal tissue is high enough to contribute to the electron spin resonance signals observed is at present under investigation.

It is also important to consider whether the electron spin resonance values obtained can be related to concentrations of free radical in a simple manner or whether the lifetime of the free radicals must be taken into account. The temperatures at which measurements were carried out (-180°C.) tended to reduce this problem; moreover, our previous work on aged rat liver¹ indicates that at the temperature of observation the free radicals present are relatively stable.

We wish to acknowledge the technical assistance of Mr. Harvey Komet and Mr. Gay Morrison.

THEORIES OF SHAPE DISCRIMINATION IN OCTOPUS

SUTHERLAND, in a recent article¹, offers an evaluation of my theory of the relation of the plexiform zone in the octopus to its shape discriminatory capacity². A critique is made both on general grounds of plausibility and in relation to specific points of experimental evidence. Dr. Sutherland seems to misunderstand my theory, for his article contains important errors. There are six main objections which will be dealt with in turn.

(1) It can be seen from Cajal's neurohistological work that the retinal fibres of the octopus terminate in the plexiform zone, which they penetrate at right angles. This plexiform zone is seen to consist of a large number of fibres lying in many layers parallel to each other. Each fibre runs only a certain distance among this plexiform zone and sends a process out of this zone deeper into the optic lobes. Beyond these neurohistological observations made by Cajal, I further proposed that we make two main suppositions. The first was that each fibre in the plexiform zone sent a message out only when two or more simultaneously active retinal fibres cross it. The second was that the fibres in the plexiform zone ran in a vertical direction in relation to the visual field of the octopus. Given only these simple suppositions, it was shown that the observed neurohistological arrangement would convert vertical distances between points into amounts of activity leaving the plexiform zone. The smaller the distance between two points, the larger the amount of activity. It was made explicit that no precise mathematical relation between distance and output was postulated. "It should also be stated that the present system has been left quantitatively flexible. It has been assumed, for example, that the vertical distance between two points leads to an output which is the reciprocal of this distance. There is no reason for supposing that the conversion is precisely this. The theory only has to assume that the conversion is something like this and then not over the whole range". The conversion will depend, among other things, on the distribution of fibre-lengths in the plexiform zone. Further, it was assumed that the output from all such vertical arrangements was summed to produce a message for each visual pattern presented to the octopus.

Sutherland, in his review, fails to mention the neural mechanism postulated. He says: "He

suggests that octopuses count distances between contours in the vertical direction at all points along the horizontal axis. The count is made in such a way that the reciprocal of the distance between contours is taken". Having thus omitted my qualifications, he then points out that as a result the number infinity will be obtained from shapes containing intersections of lines away from the vertical or horizontal axis. Apart from such considerations that, within the neural system described, counts of infinity are impossible, that infinity can be arbitrarily assigned some low value in terms of frequency of impulses, it was clearly stipulated in one of the two accessory assumptions made by me, that "excitations on the same vertical arrangement inhibit each other over a small distance".

(2) On the mechanism put forward, all shapes are transformed into a point on a dimension of amount of neural activity. Sutherland writes: "On general grounds this theory is rather implausible, since it is possible to find a horizontal or vertical rectangle which is on the same point on this dimension as any other shape however complex: it would be difficult to test this prediction, but it seems most unlikely to be correct". First of all, the deduction which Sutherland draws is incorrect. This is simply demonstrated by imagining the longest and narrowest horizontal rectangle the octopus can see. A pattern not equivalent to this can obviously be constructed by placing another such horizontal rectangle some distance above it. Such a procedure can be repeated until we have a whole field of horizontal stripes, which evidently cannot be equivalent to any horizontal rectangle. Conversely, there will be complex shapes which are not equivalent to any horizontal rectangle but to some field of stripes. What is of more interest is that he himself suggests a principle of classification for the octopus at the end of his article and in other publications on which precisely analogous equivalences can be constructed. He suggests that an analysing mechanism in the octopus is present which computes the total contour of a shape relative to its area or to the square root of its area.

Further in support of his suggestion, he reports an experiment in which there was good transfer from a butterfly shape to an elongated rectangle. Though these considerations are not claimed in support of

my theory, it is difficult to see why Sutherland regards my theory as "rather implausible" on grounds which apply to his suggestions and which, as he himself recognizes elsewhere, his own experiments tend to refute.

(3) A further criticism of my theory concerns the result of transfer tests to the same shape of different sizes. On my theory, transfer to the same shapes of different size would be predicted to varying degrees depending on both the shapes used in the original training. If we assume some kind of reciprocal relation between distance and amount of excitation on the vertical axis, then doubling the distance of two points will decrease the excitation emerging from the plexiform zone. On the other hand, if we enlarge a shape, we not only increase the distance between the contours in the vertical axis, but also increase the number of pairs of points on the horizontal axis. So, when we increase the distance vertically, we also increase it horizontally, so that the total amount of excitation for certain classes of shapes, such as squares, when scaled up or down tends to remain the same. It follows, as I further wrote: "Transfer from one shape to another will depend on two factors: (a) the shape used; and (b) the other member of the pair from which the octopus has learnt to make the discrimination. . . . As regards the first point, it will be readily seen that, if we take a V shape lying on its side and a scale enlargement of it, the scale enlargement will produce a greater output. The small V shape is a part of the larger V shape. . . ."

"This brings me to the second point. If the total amount of output from the shape to be discriminated from the other member of the pair was larger, then the increase in output due to the enlargement of this shape will not destroy the discrimination, because the effective distance along the continuum is increased. . . . There may actually be an improvement if the other parameters which the octopus derives from the stimulus also increase the distance between discriminanda". Sutherland, however, states: "Thus the theory predicts good transfer to different sized rectangles, but poor transfer to different sized triangles. These predictions are not confirmed: there is diminished transfer to all figures including vertical and horizontal rectangles when the area is reduced by a quarter. There is usually better transfer to larger figures than to smaller, though even this transfer is sometimes less than complete. The results of transfer tests to different sized figures thus constitute a direct refutation of one of the most interesting predictions made by *B* (Deutsch's theory)".

I am sorry that Sutherland has missed the point that overall trends in efficiency of transfer to different sizes are of little theoretical interest given his experimental situation. It is the comparative efficiency for a given shape, when it is being discriminated from a certain other, that is of interest. Here there are indications of variation, though the results are unfortunately confounded through a process of averaging. For example, Sutherland⁴ reports that with certain pairs of shapes the transfer to shapes of 4/9 the area is better than to the originals. He also ignores similar interesting discrepancies from his generalization to be found in another of his papers⁵. It should be clear that, for some reason, Sutherland ignores the stipulation concerning the other member of the pair of shapes being discriminated which was clearly made. In fact, so far from

making the transfer to different-sized triangles worse, I actually quoted an example from Sutherland's results in support of my theory, in which there was an improvement in accuracy of discrimination between a triangle and a square when the triangle was made larger.

I was well aware of the data on worse transfer to smaller shapes and comparatively better transfer to larger shapes which Sutherland quotes and which, according to him, "cannot be directly explained on any current theory", and for which he postulates some effect of noise in the neural analysing mechanisms. These data I carefully avoided discussing to spare Sutherland the embarrassment of pointing out that this may be explained as a simple artefact of his training situation, in which the octopus swims up to the shapes presented, thus exposing itself to progressively larger projections of the shape before it is finally rewarded or punished; however, no analogous shrinking of the shape to a smaller size than that presented is allowed to occur. We cannot, therefore, regard it as surprising that transfer to larger shapes is better than that to smaller.

In view of this, I was careful to quote only evidence which compares the effectiveness of transfer for different shapes. Sutherland has not denied the validity of these data.

(4, 5, 6) Three of Sutherland's further criticisms are again due to a failure to take note of one of the two accessory assumptions made by me:

"Before proceeding, I should make clear that for the purposes of prediction two accessory assumptions must be made . . . (2) that the octopus can also discriminate relative vertical positions of the output converted in the above way. This second appears to be a residual factor left when we have explained the rest of Sutherland's results". Though this is certainly not an explanation, it clearly limits the scope of my theory. In spite of this, the theory is criticized as if no such limitation had been made (Sutherland's points under his headings 2, 4 and 10). This failure is especially outstanding in the case of 10. I state: "It is found that the octopus can discriminate some up-down mirror images. This would be covered by assumption 2". Sutherland, however, says: "*B* [my theory] cannot account for any discrimination between mirror image shapes of this sort . . .". Such criticisms are all the more remarkable as in the very same paragraph he imports special assumptions into his own theory to explain these findings, "... behaviour is more accurately controlled by differences in the horizontal projection (on which up-down mirror images differ) than by differences in the vertical projection". He then goes on to state that using this principle of more accurate analysis on the horizontal projection to predict, it would be the case that "horizontal rectangles of different lengths will be more readily discriminable than vertical rectangles of different lengths (this follows because horizontal extent is more accurately analysed than vertical extent). This prediction was strikingly confirmed". If it were, then it disproves the theory, or shows it to be nonsense. If "behaviour is more accurately controlled by differences in the horizontal projection (on which up-down mirror images differ)" then vertical rectangles ought to be more readily discriminated, as they will differ on the same projection as up-down mirror images. The same confusion between vertical and horizontal (which Sutherland has shown the octopus can discriminate) is shown

when Young's⁴ neuroanatomical data on the dendritic fields of pick-up fibres from the input to the optic lobe are quoted by Sutherland in support of his own theory. "Moreover, there appear to be more fields orientated in the horizontal than in the vertical axis: this would be expected on the theory if the function of these cells was to compute horizontal and vertical extents". Young⁴, however, states about these structures: "Measurements on Cajal preparations show the greatest number and total length of dendrite to be in the vertical direction". Such a statement is amply borne out by the numerical analysis given by Young in Table 1 of his paper.

Young's work is fully consistent with my own theory, and his new findings enable the mechanism suggested in the theory to be applied to explain data which previously were outside its scope (for example, Sutherland⁴). It is hoped to deal with this in another publication.

In a recent article on shape discrimination in the octopus¹, I reviewed the behavioural evidence and its bearing on three theories which have been proposed. One of these theories was that put forward by me², a second was a modified form of this theory suggested by Deutsch³.

In the foregoing communication, Deutsch attempts to rebut four of the criticisms made of his own theory in the light of the evidence, and also criticizes my theory at two points. Both the experimental evidence and its bearing on theory are now rather complex, and Deutsch appears to have misunderstood some of my original article: because of the complexity of the evidence and the brevity with which it was summarized, it is possible that parts of this article were not clear to others besides Deutsch, and the present communication will attempt to expand those points at which Deutsch's article reveals that there is a possibility of misunderstanding. His points will be dealt with in turn using the same numbering as in his communication above, and an attempt made to clarify dispassionately the questions at issue.

(1) One crux in Deutsch's theory is to specify what happens when the contours of a figure approach one another in such a way that the vertical distance between contours approaches continuously to zero. Fig. 1 shows four shapes, in three of which this occurs at the corners marked with a vertical line. Deutsch's mechanism analyses shapes in terms of the closeness in the vertical direction of their contours: when the vertical distance between contours falls below a certain distance (D) no count is taken. The vertical lines in the corners of shapes in Fig. 1 represent an example of what this distance might be. I did not fail to recognize that such a distance (D) could be specified in my article¹—indeed, in my summary of Deutsch's theory I wrote that "to prevent

Fig. 1

obtaining infinity from such shapes, it would be necessary to specify some small vertical distance between contours within which no count is taken". The point at issue is that Deutsch has failed to specify what this distance is, and until it is specified it is impossible to make predictions on his theory about the discriminability of shapes with contours approaching one another in this way. This of course includes the vast majority of shapes in the octopus's normal environment, so that without specifying this distance the theory has little predictive value. However, once this distance is specified the theory would make different predictions from my own at some points. The question arises why Deutsch has failed to make his theory more precise by specifying a distance, and the answer would appear to be that whatever distance is selected predictions about some pairs of shapes are yielded which the experimental evidence already in existence shows to be false: the points at which false predictions will occur will of course vary with the actual distance specified. A second problem which Deutsch has not considered is that it is difficult to know whether to specify the distance (D) in terms of the physical size of the shape, or in terms of retinal angle. We find ourselves in a dilemma: the former alternative would require an elaborate neural mechanism to achieve constancy of visual size independent of how far from the eye a shape is placed operating before the count of vertical extents is taken. The latter alternative would mean that the count yielded by a shape would vary with its distance from the eye. Thus the question of what the vertical distance (D) is within which no count is taken is critical for Deutsch's theory since, until it is specified, the theory cannot make predictions about most shapes, and there are serious difficulties in specifying such a distance.

(2) Deutsch's claim that it would be possible to find a pattern of stripes not equivalent to a horizontal rectangle on his theory is irrelevant to the argument. My claim was that it would be possible to match any shape (not any pattern) by a vertical or horizontal rectangle of appropriate dimensions. How one evaluates the plausibility and biological utility of a mechanism which makes confusions of this sort is a matter for individual judgment. The point at issue is that Deutsch's mechanism confuses every closed shape with the appropriate horizontal or vertical

rectangle: the mechanism I proposed only confuses certain shapes, and has led to tests for whether or not these confusions actually occur.

(3) The predictions Deutsch should make about transfer to different-sized shapes can be stated succinctly as follows. Let us suppose that an animal has learned to discriminate between two shapes *A* and *B*, where *A* occupies a higher position on the dimension under analysis according to Deutsch than the position occupied by *B*. For some shapes (for example, horizontal and vertical rectangles, a square), changing their size does not alter their position on this dimension; for other shapes (for example, triangles, cf. Fig. 2 (b) in ref. 1), if the shape is enlarged, its position on the dimension is increased; if it is reduced in size, its position is decreased. We can now make the following predictions: (i) For all shapes of the former sort, transfer should be perfect to both smaller and larger shapes. This applies to both *A*- and *B*-type shapes, since neither changes its position on the dimension. This prediction has been shown to be wrong with no fewer than six pairs of shapes (horizontal and vertical rectangles⁴, square and vertical rectangle⁵, square and horizontal rectangle⁵ pairs *jk* and *lm* in Fig. 1 of ref. 1, square and cross). In all these cases transfer was found to be better to larger shapes than to smaller. The following predictions can be made of shapes which do change their position on the dimension when their size is changed. (ii) If shape *A* is enlarged transfer will be complete since it will be pushed further away from shape *B* along the dimension. It is even possible (but unlikely, cf. the experimental evidence in ref. 6) that performance may now be better than on the training shapes used. (iii) If shape *A* is made smaller, transfer will be imperfect since it is now closer to shape *B* on the dimension. (iv) If shape *B* is enlarged, transfer will be incomplete since it now lies nearer *A*. (v) If shape *B* is reduced in size, transfer will be complete (or better than complete) since it now lies further away from shape *A* on the dimension under analysis. Predictions (ii) and (iii) are of little interest since they are covered by the generalization that better transfer results with larger figures than with smaller. Nevertheless, Deutsch rests his whole case on a prediction of type (ii). From some 40 examples of transfer to shapes of different sizes to be found in my experimental papers, Deutsch selects one result and claims it supports his theory. In this experiment⁷ I had trained four animals to discriminate between a triangle (shape *A*) and a diamond (shape *B*) and four to discriminate between a triangle (*A*) and a square (*B*). When an enlarged triangle was presented transfer was better than complete. The very same experiment from which Deutsch takes this result provides data on transfer tests to three other shapes of different sizes, every single one of which gives a result contrary to the predictions which would be made on Deutsch's hypothesis. Thus we would expect worse transfer to a small triangle than to a small square, since reducing the size of the triangle (shape *A*) brings the shape nearer to the square on the dimension under analysis (prediction iii). Yet transfer to the small triangle and to the small square was the same and was complete. Moreover, when we increase the size of a diamond we bring the figure nearer to a triangle on this dimension (prediction iv), yet performance was as good as with the original diamond. Finally, if we reduce the size of the diamond, performance should improve since it moves away from the position of the

triangle (prediction v). Performance did not improve: it was the same as with the small triangle. Thus even in the one experiment which Deutsch cites as providing evidence favourable to his hypothesis on transfer, there are three cases (not mentioned by Deutsch) where the predictions his theory makes were found to be incorrect, and one (cited by Deutsch) where the prediction was right. It is about this question that he now writes, "Sutherland has not denied the validity of these data".

In his discussion of size transfer, Deutsch further writes that the better transfer to larger shapes than to smaller "may be explained as a simple artefact of his [Sutherland's] training situation". This might well have been true, were it not for two facts: (a) Better transfer to larger shapes than to smaller has been found to occur in all species tested, irrespective of the training situation used. (b) In a recent experiment (to be published), J. Z. Young has shown that better transfer to larger shapes than to smaller occurs quite independently of octopuses' previous experience with shapes of different retinal sizes.

(4) Deutsch in his original article claimed it would be possible to put a further mechanism into his theory which would account for the discrimination of up-down mirror images. In the foregoing article he says "this is certainly not an explanation": it was for this reason that I did not discuss his unspecified further mechanism. It should be noted, however, that even if a count of contour position in the vertical plane is kept, this will still not explain discrimination of left-right mirror image shapes: my original claim that Deutsch's theory "cannot account for any discrimination of mirror-image shapes of this sort" (that is, left-right) is therefore correct. It is not clear why Deutsch thinks his further mechanism is relevant to points (2) and (4) in my original article¹. He appears to be claiming that at all points where his theory makes incorrect predictions it would be possible to propose some other mechanism which would make correct predictions: this claim is irrefutable.

(5) The allegation that the greater discriminability of horizontal rectangles of different lengths than of vertical rectangles of different lengths disproves my original theory is surprising. This experiment was performed in order to test a prediction made by my own theory. Fig. 2 should help to make clear on what the prediction was based. The vertical and horizontal projections respectively represent the amount of each shape in the vertical plane at each point on the horizontal axis, and the amount of each shape in the horizontal plane at each point on the vertical axis. It should be noted that the horizontal projections have been rotated clockwise through 90°. In all my papers on this subject, it has been stated that it was the heights of these projections which are analysed, not their breadths. It is clear from Fig. 2 that left-right mirror images (pair *b*) differ only in their vertical projections, whereas up-down mirror images (pair *a*) differ only in their horizontal projections. Up-down mirror images are better discriminated by octopuses than left-right. In terms of my theory this can only mean that when discrimination is based on an analysis of the horizontal projections performance is more accurate than when it is based on an analysis of the vertical projections. This enables us to construct a further test for the theory: two horizontal rectangles of different lengths differ in the height of their horizontal projections,

Fig. 2

two vertical rectangles differ in the height of their vertical projections (cf. Fig. 2, pairs c and d). The theory must predict that the horizontal rectangles will be better discriminated than the vertical. This prediction was confirmed. In my original article, I said it was "strikingly" confirmed; the difference in performance of animals trained on rectangles in different orientations was very large and was significant at better than the 0.00001 level of confidence⁵; also this was a new and (to common sense) unexpected discovery about the octopus, which would not have been found out if the theory had not been manipulated to yield predictions.

(6) Deutsch's final point appears to involve certain misconceptions about neuroanatomy and in particular about Young's recent findings⁶. From a functional point of view, what is likely to be important is not simply the total length of dendrite running in the direction corresponding to a given optical axis, but the orientation of dendritic pick-up fields. Young has tentatively interpreted his own findings to mean that there are more dendritic fields orientated in a plane corresponding to the visual horizontal than in any other plane. This might produce better discriminability of horizontal extents than of vertical, and is therefore in line both with the behavioural evidence and with my speculative interpretations. To consider only the direction in which fibres are running, which is what Deutsch appears to be doing, is like trying to draw conclusions about a radio set by looking only at the directions in which wires go without considering how they are linked up. On Deutsch's own theory we would expect to find better discriminability of vertical than of horizontal

distances, and correspondingly more vertically orientated pick-up fields than horizontally orientated; thus the theory appears to be at variance both with the existing neuroanatomical and behavioural evidence.

In conclusion, it may be worth attempting to draw some lessons of a more general kind from this controversy. From behavioural data alone it is not possible to specify the exact neurophysiological mechanisms at work and it would be presumptuous for a psychologist to attempt to do so. Such specification must await the results of detailed neurophysiological and neuroanatomical studies: in the existing state of such studies it is only too easy for the psychologist to produce howlers in his attempts to interpret them. All the psychologist can hope to do is to specify the general lines along which data are processed in the system. I have attempted to work out by systematic experiment some of the ways in which visual data are processed by the octopus: any neurophysiological hypotheses I have proposed have been put forward only to give concrete instances of the sort of thing that may be happening, and as a help in framing hypotheses which may be tested at a behavioural level. Deutsch does not challenge the outlines of the data-processing system, that is, that there is an analysis of shape along the x and y co-ordinates with a greater accuracy of analysis on the horizontal co-ordinate. The point of neurophysiological speculation at this stage is only that thinking in concrete terms may help to produce hypotheses which can be tested by behavioural experiments: it is in fact heuristically valuable and in the case of the octopus has helped me in the assembly of systematic data on this species' capacity for shape recognition, and in the discovery of some surprising facts. These facts may help in the interpretation of neurophysiological and neuroanatomical data when more complete data of this sort become available. Unfortunately, Deutsch's theory has not led to the discovery of any facts, nor has it yet made any new and correct predictions; if further specifications could be added, then it too might become valuable as a research tool. The body of experimental data on shape recognition in the octopus, collected by Young, Boycott, Muntz and Sutherland, is now fairly extensive; for almost any theory which could be proposed it would be possible to select a few facts out of many, quote them out of their experimental context and claim that these facts fit the theory. The progress of a science is not favoured, however, if in doing this we take no note of the facts which do not fit the theory; these may be the most important points at which to start further work.

The work discussed in this article was undertaken as part of a project on "Stimulus Analysing Mechanisms"; this project is jointly financed by the American Office of Naval Research (Contract N62558-2453) and the Nuffield Foundation. I am grateful to these institutions for their financial support.

LETTERS TO THE EDITORS

PHYSICS

Pressure Dependence of Resistivity of Indium Antimonide to 70,000 Atmospheres

THE pressure dependence of the resistivity of indium antimonide has been measured by Keyes¹ up to 12,000 atmospheres. We have extended the range to 70,000 atmospheres. In addition to the type of change found by Keyes we have observed a resistance change on melting when the temperature was considerably below the zero pressure melting-point of 796° K.

The measurements were made in a tetrahedral apparatus constructed at the National Physical Laboratory following a design of the National Bureau of Standards². This allows the use of a standard hydraulic press. In our apparatus the pyrophyllite tetrahedron had a side of $\frac{3}{8}$ in. and electrical connexions were made by the techniques described by Hall³. Cooling coils allowed the temperature to be lowered to 120° K. Pressure-versus-load calibration was made by measuring resistance changes in bismuth, thallium and barium specimens and using Bridgman's electrical data⁴.

Fig. 1 shows typical behaviour of single-crystal specimens of indium antimonide at two temperatures. Initially, the resistance increases with pressure as found by Keyes, who showed that this effect comes mainly from a widening of the energy gap. In our room-temperature experiments, the resistance dropped sharply at a pressure of 30,000 atmospheres. This is attributed to melting, with a transition from semi-

Fig. 1. Behaviour of single-crystal specimens of indium antimonide at two temperatures. $\times$ type $\sim 4 \times 10^{14}$ electrons/c.c. Specimen size, $1\frac{1}{2}$ mm $\times$ $1\frac{1}{2}$ mm. $\times$ 3 mm. O, 293° K.; $\times$, 184° K.

Fig. 2. Effect of pressure on the melting point of indium antimonide

conduction in the crystal to metallic conduction in the liquid phase. In support of this, the ultimate resistivity reached here is close to the value obtained by Busch⁵ for liquid indium antimonide at zero pressure. The small pressure dependence of the resistivity in the liquid phase is also consistent with the metallic behaviour demonstrated by Busch.

Fig. 2 shows the melting point, as measured by the sharp fall in resistance, plotted as a function of pressure. It shows a decrease with increasing pressure which, qualitatively, is consistent with the known contraction in volume on melting shown by this compound. The decrease varies linearly with pressure to about 30,000 atmospheres, but significantly departs from this behaviour at higher pressures. By inserting a value of the slope of our melting curve at zero pressure in the Clausius-Clapeyron equation with a known value⁶ of the volume contraction on melting ($\Delta v/v_{\text{solid}} = 0.13$) a value for the latent heat of fusion can be found. This value of 27 cal./gm. does not agree with an experimentally determined value⁷ of 47.2 cal./gm. The disagreement between these values might arise from the presence of complex phases in the liquid near the melting point⁸. In our experiments results are lacking below 10,000 atmospheres because the pyrophyllite gasket technique is not reliable.

It is interesting to compare the corresponding work on the melting of germanium by Hall⁹. In this he finds a variation of melting point with pressure which is substantially linear over the range 0–180,000 atmospheres. When his value of the slope of the melting curve is used to calculate the latent heat of fusion, using a measured value¹⁰ of the volume change, a value of 84 cal./gm. is found which is in fair agreement with the experimentally determined value of 110 cal./gm.¹¹.

Diffusion of Cadmium into Gallium Arsenide

DIFFUSION of cadmium-115 into gallium arsenide has been examined by a method identical to that described by us¹ in the case of zinc-65. The cadmium was diffused from a saturated vapour into a carefully prepared specimen of gallium arsenide approximately 1 cm. × 0.4 cm. × 0.2 cm. contained in a quartz tube 2 cm.³ in volume. After diffusion auto-radiographs of the specimen were taken to check the uniformity of activity across the surface and the diffusion profile was obtained by sectioning as described in the reference.

Fig. 1 shows typical diffusion profiles after diffusion for 40 hr. at 1,000° C. with the cadmium source held at 750° C.

The initial decrease in concentration from 2×10^{19} cm.⁻³ at the surface is very rapid. Fitting this part of the curve to a complementary error function, an approximate diffusion coefficient, D , of 3×10^{-12} cm.² sec.⁻¹ can be obtained. The concentration falls to a minimum, which is sometimes below the limit of detectability, but rises again to a maximum followed by a much more gradual decrease. Twelve different specimens have been examined and all have shown the same qualitative results. The half-life of the deeply penetrating activity has been measured and found to be the same as that of the irradiated cadmium, thus ruling out the possibility that the effect is due to an impurity in the cadmium. Although the steeply falling portion of the profile is reproducible, the concentration at the subsequent maximum has varied between 4×10^{18} cm.⁻³ and $\sim 10^{19}$ cm.⁻³ in a manner which is at present unaccountable.

Fig. 1. Cadmium concentration versus distance from surface. Diffusion temperature, 1,000° C.; diffusion time, 40 hr.; cadmium source temperature, 750° C.

Goldstein² has also examined the diffusion of cadmium into gallium arsenide and fits his results to simple complementary error functions. The value of D which he obtains for 1,000° C. is somewhat higher than that which we obtain from the steeply falling portion of our curves. He does not report any anomalies in his results such as we have found. However, it should be noted that his conditions of diffusion are somewhat different from ours, and in particular he has chosen to carry out diffusion in the presence of an arsenic atmosphere.

In an attempt to explain this behaviour experiments have been performed using:

- (1) crystals of different conductivity type;
- (2) crystals orientated so that diffusion along [111], [111]; [110] or [100] directions was examined;
- (3) crystals strained to produce a large concentration of dislocations.

No correlation has been found between these crystal properties and the characteristics of the diffusion profile.

Further experiments to elucidate the mechanism of this diffusion are in progress.

We wish to thank the Admiralty for permission to publish this communication, Mr. W. R. Harding for supplying the gallium arsenide and Mr. N. Fleet for assistance with the experiments.

Fine Structure of the Nuclear Magnetic Resonance Spectra of Solids: Chemical Shift Structure of the Spectrum of Phosphorus Pentachloride

THE static dipolar interaction between the nuclei in a solid causes its nuclear magnetic resonance spectrum to be much broader than that of a liquid. In the liquid state the isotropic re-orientation and diffusion of the molecules average their nuclear dipolar interaction almost to zero, often revealing a

Fig. 1. Phosphorus-31 magnetic resonance spectrum of polycrystalline phosphorus pentachloride rotated at high speed. The resonance frequency of the reference compound (85 per cent aqueous phosphoric acid) is also indicated; this frequency was determined from recordings taken immediately beforehand and afterwards

fine structure originating from the different chemical shifts of the nuclei, and from their indirect spin-spin interactions. In solids this fine structure is obscured by the stronger dipolar interactions. As we have shown previously¹⁻³, the dipolar broadening may nevertheless be removed in solids also, the necessary averaging being achieved by high-speed rotation about an axis inclined at an angle $54^\circ 44'$ to the direction of the applied field. When the rotation-rate is comparable with the static line-width, the narrowed central line is resolved from the satellite lines which appear on either side of it at integral multiples of the rotation frequency. Thus, for example, rotation of solid sodium chloride at a rate of 800 c./s. gives a resolved sodium-23 spectrum consisting of a central line and three pairs of satellites⁴. At a rotation-rate of 1,600 c./s. the central line and only one pair of weak well-resolved satellites are observed, while at 2,500 c./s. only the narrow central line is visible.

High-speed rotation at the angle $54^\circ 44'$ thus opens up the possibility of observing fine structure in solid specimens, and may therefore be useful in studying insoluble compounds. There is in any event interest in comparing the fine structure of spectra for the same compound in both the solid and the liquid states.

A first example of the application of this method is provided by polycrystalline phosphorus pentachloride, which gave the phosphorus-31 resonance spectrum shown in Fig. 1. The sample was placed in an airtight container which was rotated about an axis making an angle of $54^\circ 44'$ with the steady magnetic field of about 4,740 gauss. The satellite lines were scarcely distinguishable from the noise background and the central spectrum consists of two sharp lines of approximately equal intensity. It is known from the X-ray diffraction examination by Clark, Powell and Wells⁵ that in the solid state phosphorus pentachloride consists of equal numbers of tetrahedral $(\text{PCl}_4)^+$ and octahedral $(\text{PCl}_6)^-$ ions arranged on a tetragonal lattice. It is therefore reasonable to identify the two spectral lines with phosphorus nuclei in the two types of ion, the separation between the lines arising from their different chemical shifts. The spectrum has also been recorded in a field of about 3,550 gauss; the separation between the lines is found to be proportional to the field strength as the chemical shift explanation requires.

The chemical shifts of each line have been measured relative to the usual phosphorus standard, 85 per cent aqueous phosphoric acid, and are found to be +281 and -96 p.p.m. (The spectra were measured

using a fixed field and a variable radiofrequency. The shift is therefore defined as $(\nu_r - \nu_c)/\nu_r$, where ν_c and ν_r are the frequencies for the compound and the reference respectively. This is equivalent to the usual definition $(H_c - H_r)/H_r$, when the frequency is held constant and the field is varied.) These shifts fall within the range +488 to -222 p.p.m. recorded for various liquid specimens⁶. Since there are equal numbers of the two types of phosphorus nuclei one cannot determine from the spectrum itself the assignment of the two lines to their respective ions. There is some indication that positive shifts arise when more than four atoms are connected to a phosphorus atom⁶. The shift for molecular PCl_5 in carbon disulphide solution is +80 p.p.m.⁶ whereas for PCl_3 it is -215 p.p.m.⁶. The $(\text{PF}_6)^-$ ion, which like $(\text{PCl}_6)^-$ is an octahedral sp^3d^2 hybrid, has a shift of +148 p.p.m. in hexafluorophosphoric acid⁷. It seems likely, therefore, that the positively shifted line in solid phosphorus pentachloride arises from the $(\text{PCl}_4)^+$ ion, though this assignment cannot be certain. If the assignment is correct we have the following sequence of shifts in p.p.m. for four phosphorus chlorides: PCl_5 (-215), PCl_4^+ (-96), PCl_3 (+80), PCl_2^+ (+281).

We have found evidence that when the rotation-rate is a submultiple of the separation between the two lines, so that the satellites of each line are superposed on the central line and satellites of the other, there is an exchange of energy between the two systems of nuclei. This feature is being examined in more detail.

Line Breadths in the Ammonia Spectrum

THE Van Vleck-Weisskopf formula for peak absorption and specified for the ammonia inversion spectrum in the microwave region can be written¹:

$$\gamma_m = \frac{A}{\Delta\nu} f(J, K) \quad (1)$$

$$\text{where } A = \frac{6\pi^2 N f \mu^2}{3ckT} \sqrt{\frac{B^2 Ch^2}{\pi(kT)^3}}$$

$$\text{and } f(J, K) = g \frac{(2J+1)K^2}{J(J+1)}$$

$$\nu_0 \exp \left\{ -\frac{14.3}{T} (J(J+1) - 0.366K^2) \right\}$$

There is evidence that $\Delta\nu$ varies with rotational state for the $J = K$ transitions as $\left(\frac{K^2}{J(J+1)}\right)^{1/n}$, where n has the value* of either 2 or 3. If $\Delta\nu$ is normalized to the (3,3) line, as seems to be the present practice, then $f(J,K)$ in equation (1) should be multiplied by

$$\left(\frac{3J(J+1)}{4K^2}\right)^{1/n}, n = 2 \text{ or } 3 \quad (2)$$

The factor in equation 1 limiting an accurate prediction of intensity has been the value of $\Delta\nu$. Experimental intensity results have not previously warranted a more precise value of $\Delta\nu$. However, the development and construction of an improved microwave spectrometer at this University has allowed accurate measurements to be made on the intensities of absorption lines. A number of lines in the ammonia inversion spectrum have been measured ($J = K$, 1 to 6), and the results of these measurements are shown in Table 1. Column 3 lists the values predicted in Townes's "Microwave Spectroscopy".⁴

Table 1. TABLE OF PEAK ABSORPTION COEFFICIENTS OF AMMONIA MEASURED AT $T = 27^\circ\text{C}$. AND IN THE PRESSURE REGION OF 0.1–0.5 MM. MERCURY

(J,K)	γ_m measured ($\times 10^{-4}\text{ cm.}^{-1}$)	γ_m calculated (ref. 6) ($\times 10^{-4}\text{ cm.}^{-1}$)
1,1	1.81 ± 0.09	1.9
2,2	3.10 ± 0.11	3.2
3,3	7.87 ± 0.11	7.9
4,4	4.16 ± 0.03	4.3
5,5	3.87 ± 0.04	4.0
6,6	6.66 ± 0.08	6.9

The experimental values of γ_m have been plotted against $Af(J,K)\left(\frac{3J(J+1)}{4K^2}\right)^{1/2}$ in Fig. 1. The value of the line-breadth parameter found from the straight line is:

$$\Delta\nu = 25.7 \pm 0.2 \text{ mc./s. per mm. mercury at } 27^\circ\text{C.}$$

The results of this experiment did not distinguish between the values of $n = 2$ and $n = 3$ in expres-

Fig. 1. Experimental intensity measurements of $J = K$, 1–6 ammonia inversion lines plotted against

$$Af(J,K)\left(\frac{3J(J+1)}{4K^2}\right)^{1/2}$$

sion (2). The value of $n = 2$ was chosen because of its more generally accepted theoretical basis*.

Yamano has measured $\Delta\nu$ and found it to be 27.5 ± 0.1 mc./s. per mm. mercury at 24.5°C . and to hold in the pressure region of 0.01–0.02 mm. mercury*. If $\Delta\nu$ is assumed to vary as T^{-1} then under similar temperature conditions the value obtained here is some 2.3 per cent less than that of Yamano.

A more detailed report will be published in due course.

Sustained, Localized, Pulsed-Microwave Discharge in Air

SEVERAL recent publications^{1–4} discuss possible methods whereby a localized gas discharge might be maintained by electromagnetic radiation. Recently a simple experiment to maintain an electrodeless discharge by focused microwave radiation was undertaken at this Laboratory. A small, localized discharge was obtained in low-pressure air. This discharge stands distinct and isolated from the generating apparatus and from any walls.

A pulsed, X-band radar transmitter is used as a microwave source. This unit emits pulses of approximately 0.5 μsec . duration, providing 40 W. average power and about 20 kW. peak power with an interpulse time of 200 μsec . These figures are nominal because stationary waves set up by the experiment cause deterioration of the magnetron. A pyramidal horn on the radar output is directed toward an 18-in. parabolic reflector 2 ft. away. An evacuated, roughly spherical glass chamber about 6 in. in diameter is placed at the focus of the paraboloid. A corona discharge from a Tesla coil is employed momentarily to provide the initial ionization within the chamber when the discharge does not occur immediately upon turning on the transmitter. A red or violet discharge is formed at the focus within the chamber. The size of the discharge is variable, the maximum dimension ranging from about 1 to 4 cm.

Several factors influence the appearance of the discharge. At pressures from about 3 to 20 mm. mercury its shape is irregular, exhibiting several striations. At higher and lower pressures, the discharge takes on the shape of one or two 'sausages' with their long axes in the direction of the electric vector of the microwaves from the transmitter. At about 0.3 mm. mercury, the lowest pressure at which it can be maintained, the discharge is red and diffuse. As the pressure is increased, the discharge gradually becomes definite in its configuration and violet in colour. At about 6 mm. mercury the colour is a bright violet and the edges are well defined. This remains true as the pressure is increased to 47 mm. mercury,

the highest pressure at which the discharge has been maintained.

Movement of the glass chamber modifies the shape of the discharge. This, as well as the striated appearance, is attributed to perturbations of the electromagnetic field by internal reflexions from the chamber walls. These reflexions can sometimes split the discharge into two or, rarely, three parts. However, the discharge does not move with the chamber. The position of the discharge is clearly determined by the transmitter-reflector geometry and can be obtained at any point within the chamber. If the discharge is brought into contact with the walls of the chamber, it will spread along a portion of the wall. If the focus is moved to the outside of the chamber, the discharge is extinguished.

There is no noticeable increase in the temperature of the chamber if the discharge is not brought in contact with the wall. When such contact occurs, the wall becomes warm and is uncomfortable to touch within 10 sec.

I wish to thank Messrs. Donald J. Ritchie and Carl P. Tresselt for their part in planning and carrying out these experiments.

CRYSTALLOGRAPHY

Crystal Structure of $\text{Ba}_{0.5}\text{TaO}_{2.5}$

A STUDY of the barium-tantalum-oxygen system has produced the compounds Ba_2TaO_6 with an ordered perovskite structure¹, $\text{Ba}_2\text{Ta}_2\text{O}_{12}$ with a hexagonal layer structure², $\text{Ba}_{0.5}\text{TaO}_3$ with the tetragonal bronze structure³, and $\text{Ba}_{0.44}\text{TaO}_{1.84}$, a hexagonal phase for which a trial structure has just been determined. The preparation of a powder and a single crystal of the reduced phase, $\text{Ba}_{0.44}(\text{Ta}_{0.74}\text{Ta}_{0.26})\text{O}_{1.87}$, as well as analogous phases has previously been described⁴. It was later found that this reduced phase was produced only when the tantalum pentoxide used in the preparation was obtained from a particular source. The method of preparation is to mix appropriate quantities of tantalum pentoxide, tantalum metal, and barium oxide and heat in vacuum. Attempts to prepare larger amounts of the phase for density measurements after the original source of tantalum pentoxide was exhausted, were unsuccessful unless a barium chloride flux was added. The preparations obtained with the use of the flux, however, were not homogeneous, and good density measurements were therefore not obtained.

Single crystal studies indicate that the reduced phase has the same cell size ($a = 8.96 \text{ \AA}$, $c = 7.79 \text{ \AA}$) and structure as the oxidized phase. Since crystals of the reduced phase were easier to prepare, they were used for the structure determination.

Intensities were obtained for $hk0$ and $h0l$ zones on a Buerger precession camera using molybdenum $K\alpha$ radiation. A sharpened $hk0$ Patterson projection

was prepared. With the aid of a suggestion from Dr. A. D. Wadsley as to the possible structural relationship to $\text{K}_2\text{V}_2\text{O}_7$ ⁵, it was seen almost at once that placing six tantalum ions in the positions $x, 0, \pm z$; $0, x, \pm z$ and $\bar{x}, \bar{x}, \pm z$ with $x = 0.23$ would account for the most important peaks of the vector map. These were the positions of 3/5 of the vanadium ions in $\text{K}_2\text{V}_2\text{O}_7$. The bariums were placed in the potassium positions, $x, 0, z$; $0, x, z$; $\bar{x}, \bar{x}, z$, and x was determined as about 0.63, by an $h00$ Fourier line projection. Of the possible space-groups only $P62m$ would allow these positions.

From the $00l$ data, it was determined that a reasonable fit could be obtained if three tantalums were placed at $z = 0.25$, three at $z = 0.75$, and three bariums at $z = 0.50$. An $h0l$ Patterson projection and a subsequent $00l$ Fourier line projection showed that z for the tantalums should be about 0.24 and 0.76 and the bariums should be at about $z = 0.50$.

As for the oxygen packing the neatest arrangement would appear to be oxygens directly above and below each tantalum (a scheme that accounts so well for the axial length) and oxygens at the same z values as tantalum to make groups of three corner-sharing octahedra. The approximate co-ordinates for the atoms so obtained are given in Table 1.

Table 1

Atoms	x	y	z
3 Ba in (g)	0.63	0	0.50
6 Ta in (t)	0.23	0	0.24
30 ₁ in (g)	0.23	0	0.50
30 ₂ in (f)	0.23	0	0
30 ₃ in (t)	0.84	0	0.24
120 ₄ in (t)	0.47	0.18	0.24

Using the above parameters for the atoms a fair fit was found for observed and calculated $hk0$ and $00l$ structure factors ($R = 0.24$).

The following points are disturbing about the trial structure: (1) There are marked deviations from Pauling's electrostatic valence rule in that the sum of strengths of electrostatic bonds to oxygens from adjacent cations is as low as 1.23 for some oxygens and as high as 2.27 for others. (2) The trial structure leads to an empirical formula of $\text{Ba}_{0.5}\text{TaO}_3$ with no obvious explanation of the observed fixed ratio of Ba : Ta of about 0.44. (3) There are only 18 oxygens occupying 24 crystallographically available positions (still fewer in the reduced phase), thus leaving considerable unfilled volume, again for no obvious reason. (4) The X-ray density based on the trial structure is lower than the observed range of values.

The obvious thing to try would be the inclusion of a greater number of cations, and therefore oxygens, in the structure. Judicious placement of the additional cations could favourably change the situation with respect to all the points raised above. However, so far, all attempts to add atoms to the structure have led to a greater deviation of observed from the calculated structure factors.

It is hoped that we shall be able to collect more complete data on this compound. Our intention is then to substitute a machine Fourier approach, with the described trial structure as a starting point, for the human semi-logical semi-intuitive approach we have so far been using. (It may be pointed out that this latter approach is somewhat handicapped because the structure is non-centrosymmetric.) Should these efforts prove fruitful, the results will be reported at another time.

GEOLOGY

Spectral Reflectivity of Ore Minerals

It would appear that there may have been some ambiguity in the use of the terms 'standard reference surfaces' and 'standard values' in our recent article on the above subject¹. The standard reference surfaces specifically refer to a polished basal section of quartz and to liquid mercury under a coverslip, which were measured for us by the National Physical Laboratory. The intention was that these two surfaces would be readily reproducible by other workers. The confusion has arisen in that two other surfaces of intermediate reflectivity were also measured for us by the National Physical Laboratory to assist in the calibration of our equipment. It is entirely incidental that these two 'other surfaces' were hematite and pyrite; their identity is immaterial and the values of reflectivity quoted for them are not standard values, *sensu stricto*, since minerals will, in many cases, show a range of reflectivity due to variable composition and optical anisotropy.

GEOCHEMISTRY

Pigments of a Fossil Echinoderm

SEVERAL years ago, I described¹ the discovery of crystallized organic pigments ('fringelite') in a fossil crinoid (*Millericrinus*) of upper Jurassic age. Additional specimens have now been collected at the two original locations (Fringeli and Liesberg, both in north-western Switzerland). The pigments are isolated by solvent extraction and separated by repetitive chromatography and fractional crystallization. Six pigments (fringelite A-F) have been isolated: additional pigments remaining in the fossil after exhaustive extraction with pyridine can be dissolved in concentrated sulphuric acid in which they exhibit an absorption spectrum similar to that of the more soluble fringelites. All these pigments are similar in respect to their absorption spectra, the colour of their solutions (red in organic solvents, green in sulphuric acid), the formation of green, insoluble sodium salts and the ease with which acetyl- and benzoyl-derivatives are formed. In all these properties the fringelites strongly resemble extended quinones of the type of aphin² or hypericin³.

Fig. 1. Spectra of fringelite and derivatives. Solvent, methanol. I, fringelite E; II, acetyl derivative of fringelite E; III and IV, hydroacetyl derivatives; V, fossil alkyl-benzperylene

They even give the characteristic aphin-reaction, a blue(-violet) colour, on treatment with acetic anhydride containing a small amount of sulphuric acid.

The visible and ultra-violet absorption spectrum of fringelite E in methanol (Fig. 1, curve I) shows a general resemblance to that of erythroaphin⁴ (ref. 4); however, differences in band positions and relative extinctions of the band systems at 450 and 550 mμ indicate the presence of a similar but not identical chromophoric system. The acetyl-derivative of curve II is obtained by exhaustive acetylation with pyridine-acetic anhydride. Hydroacetyl derivatives (curves III and IV) are formed by reduction with zinc dust in the same medium. Curve IV, except for a displacement to longer wave-lengths (amounting to 13.5 mμ for the main band at 298.5 mμ and 8 mμ at 383 mμ, both in methanol), is nearly identical with that of the 6-ring aromatic hydrocarbon 1.12-benzperylene; curve III shows the typical bands of highly substituted phenanthrenes. The same phenanthrene band system is also evident in curve II (the acetyl pigment) in addition to absorption at longer wave-lengths caused by the carbonyl groups of the quinone.

From these spectral data we conclude that the fringelites are polyhydroxyquinones of 1.12-benzperylene. The aromatic hydrocarbon is substituted by the quinone oxygens in such a way that three aromatic rings with phenanthrene configuration remain undisturbed. By hydrogenation this quinone is reduced to the hydroquinone with the benzperylene spectrum IV, which, by more vigorous treatment, is transformed into the phenanthrene-derivative III.

The ultimate reduction products obtained in the laboratory and in Nature provide further proof for

this structure. Zinc-dust fusion⁵ leads to 1.12-benzoperylene-type hydrocarbons of varying degrees of substitution, in addition to small amounts of a pyrene derivative. An alkyl-benzoperylene also occurs naturally in the fossil sea lily¹.

The various fringelites seem to differ mainly in the number and position of their hydroxyl groups. The spectral data and the formation of a pyrene-derivative in the zinc-dust fusion suggest that the quinone-oxygens are located in 4 and 9 positions. The presence of alkyl substituents, the position of which is not yet clear, is indicated by a considerable spectral band shift from the synthetic benzoperylene to the fossil hydrocarbon and the products of the zinc dust fusion. However, the 6 and 7 positions do not seem to be bridged by an alicyclic ring or substituted by an alkyl-chain since coronene is not formed in the zinc-dust fusion.

It has been suggested⁶ that the pigments of recent crinoids are closely related to the hydroxynaphthoquinones of other echinoderms (echinochromes, spinochromes). In my previous paper I had suggested that the fringelites and the fossil benzoperylene are the products of successive redox and condensation reactions between two echinochrome molecules, a hypothesis that has been further corroborated by the present findings. Fringelite *F* and the even more polar materials soluble only in concentrated sulphuric acid would be the primary condensation products; they are also the major pigments (several gm./kgm. of the fossil). The small amounts of the less polar pigments (mgm./kgm. for fringelites *D* and *E* and μ gm./kgm. for pigments *A*, *B* and *C*) and the hydrocarbon have been formed from the major pigments by reduction and elimination of substituents.

The highest pigment concentration occurs in the massive (2–3 in. diameter) roots and lower parts of the stem; small stems ($\frac{1}{4}$ in. diameter) and crowns rarely contain more than traces of pigments. Other fossils of the same locations, including small sea urchins and their spines, are completely devoid of pigments. Apparently, conditions for the preservation of the pigments were sufficiently good only below the sediment-water interface where the roots and heavy stems accumulated during or immediately after the lifetime of the crinoids.

Discovery of the fringelites is geochemically significant, permitting for the first time the reconstruction of a complex reaction sequence, involving reduction, condensation, oxidation and further reduction and elimination of substituents under the final formation of a polynuclear aromatic hydrocarbon. A knowledge of such transformation reactions permits conclusions about the chemical environment and the organic reactivity in the sub-surface.

A more detailed report of this work is being prepared for publication in *Geochimica et Cosmochimica Acta*. This investigation has been supported by a research contract with the United States Office of Naval Research (Contract NONR-2196 (00)).

Exposure Ages for Iron Meteorites

Schaeffer and Fisher¹ have given values for the exposure ages (that is, the time during which the meteorites were exposed to cosmic rays after having been broken out of a bigger body) of 18 iron meteorites. These ages vary between 20×10^6 to $1,900 \times 10^6$ years. I think these authors have made some mistakes in interpreting the results of their experimental work.

Exact determinations of the exposure ages of meteorites are only possible by combining the values of a stable and a radioactive cosmic-ray spallation product. For measurements of radioactive spallation products big samples are needed, and therefore only few such determinations were made. If one knows the size of the meteorite before passing the Earth's atmosphere and the location of the sample analysed inside the meteorite, it is possible to calculate the exposure age from the content of any stable spallation product alone. Unfortunately, we do not know the location of the samples or, better, their distance from the original surface of the meteorites.

Schaeffer and Fisher tried to calculate the 'depth' of the samples from the ratios of the content of different stable spallation products and based this calculation on two assumptions:

(1) The energy spectrum of the particles which produce nuclear spallation varies with the distance from the surface and with the size of the meteorite. Because of the secondary particles which have relatively low energies, the mean energy of the particles producing spallations decreases with the depth from the surface.

(2) The ratio of helium-3 to argon-38 is a measure for the mean energy of the particles.

Schaeffer and Fisher used this ratio to calculate the depth of the samples analysed and then determined from the total amounts of helium-3 the exposure ages of the meteorites.

There are errors in both of these assumptions.

(1) The energy spectrum of the primaries extends from at least 500 MeV. to several BeV. Especially from data on meteorites an extension down to about 200–300 MeV. seems very probable^{2,3}. These low-energy primaries lie in the same energy-range as the secondaries. For particles of this energy-range of several 100 MeV., the diminution by loss of energy through ionization and excitation is not negligible apart from the diminution by nuclear absorption. By this loss of energy the mean energy of the primary particles increases with the distance passed in the meteorites. This increase of the mean energy of the primaries is balanced in big meteorites by the low-energy secondaries; and even the ratio of the flux of the secondaries to the flux of the high-energy primaries (with energies > 1 BeV.) reaches a nearly constant value already for a depth of about 30 cm. caused by the diminution of the secondaries by loss of energy through ionization and excitation⁴.

(2) The ratio helium-3/argon-38 seems not at all a good measure for the energy of the particles which produce the spallation processes. This ratio should be nearly independent of the particle energy⁴⁻⁶.

As neither assumption can withstand intensive examination, the exposure age based on them cannot be correct.

Some exact determinations of the exposure ages of meteorites are known, for which Schaeffer and Fisher

also have given values. Fireman⁷, measuring argon-39 and helium-3, found the same age for Treysa and Sikhote-Alin meteorites; nearly the same results were found by me^{8,9}. Schaeffer and Fisher, however, gave the age of Treysa as being more than ten times higher than that of Sikhote-Alin. I have also tried to find, at least approximate values for the exposure ages of iron meteorites from the results of stable spallation products only; these results will be published in due course.

⁹ Wänke, H., *Z. Naturforsch.* (in preparation).

In our communication it was pointed out that it is possible to estimate a cosmic-ray exposure age for a meteorite from a measurement of the stable rare gas contents alone. The difficulty with such estimates in the past has been that it was not possible to estimate the cosmic-ray production-rate of a stable nuclide in the particular sample of the meteoroid measured, as the production-rate depends on the unknown depth of the measured sample in a meteoroid of unknown size. The proposed estimate of production-rate was made from the observation that for meteorites with low argon-39 and chlorine-36 activity (that is, low cosmic-ray nuclide production-rates) the ratio helium-3/argon-38 is lower than in meteorites with high argon-39 and chlorine-36 activities. It was also pointed out that the same is true for the ratios helium-3/helium-4 and neon-21/argon-38. The discussion of the dependence on energy of these ratios was included to give a possible explanation for the observed dependence. The only assumptions made were that the dependence is not a coincidence or an experimental error. This argument has been discussed by Wänke in the preceding communication. Contrary to Wänke's statement, the estimation of the exposure ages is not based on assumptions concerning the energy spectrum of the cosmic-ray particles producing the rare gases or on whether the ratios are a measure of the mean energy. The estimation is based only on experimental observations which indicate a relationship between the ratios helium-3/argon-38, helium-3/helium-4, neon-21/argon-38 and the production-rate of the radioactive nuclides chlorine-36 and argon-39 by cosmic rays.

The relationship found is to be expected from the results of the measured proton-production cross-sections cited by Wänke^{1,2}. It was found that the proton-production ratio $\sigma_{He} + \sigma_T/\sigma_{Ar}^{39}$ (which is to be compared to helium-3/argon-38 in meteorites) changes from about 8 with 400 MeV. protons to 23 with 3 BeV. protons; while the proton-production ratio $\sigma_{He}^3 + \sigma_T/\sigma_{He}^4$ changes from 0.19 at 400 MeV. to 0.26 at 3 BeV. The results on the neon production

are at present too fragmentary for a comparison; however, from the systematics of spallation processes (Friedlander, G., private discussions and ref. 3) it is to be expected that the ratio neon-21/argon-38 will show a similar change. These cross-section measurements indicate that the proton-production ratios helium-3/argon-38, helium-3/helium-4 and neon-21/argon-38 change with proton energy and lead one to suspect that this is the reason for the variation of the ratios in meteorites.

On the other hand, more recent, but preliminary, results⁴ indicate that the ratio helium-3/argon-38 does not vary with energy. In addition, recent measurements of Signer and Nier⁵ indicate that in a given meteorite the ratio helium-3/argon-38 is constant to at least 5 per cent while the helium-3/helium-4 and neon-21/argon-38 ratios vary by about 15 per cent. Both these observations are in agreement with Wänke's statement that the ratio helium-3/argon-38 is not a good measure of the mean energy of the particles.

If this view is substantiated by further experiments, then the observed relation between cosmic-ray production-rates and the helium-3/argon-38 ratio must have some other explanation. For example, as pointed out by Wänke, the ratios of primary to secondary particles may vary depending on the meteorite size or location of the sample inside the meteoroid. In any event, the use of the helium-3/argon-38, helium-3/helium-4 or neon-21/argon-38 ratio to estimate a cosmic-ray production-rate is based on an empirical relationship and can be disproved only by further experiments.

This work was carried out under the auspices of the U.S. Atomic Energy Commission.

CHEMISTRY

Crystal Structures of 1-Chloro-2,4-Dinitrobenzene and 1-Bromo-2,4-Dinitrobenzene

THE rates of reaction for nucleophilic aromatic substitution are affected if the replaced group has one, or two, groups ortho- to it. In particular, the effects of nitro groups in these positions (and in meta- and para-positions) have been studied in many reactions. Generally, these groups contribute two competing effects which control the reaction-rate. First, a maximum activation through electron transfer is attained if the nitro group is planar with the benzene ring. However, spatial considerations often forbid this coplanarity in the case of ortho-substitution, and there exists a competing de-activation due to the twist of the nitro group from the plane of the benzene ring. In the extreme case of two ortho-substituents, the activating effect of the nitro groups

is greatly diminished by this steric effect and may result in a net de-activation.

The reaction-rates of many nucleophilic reagents with 1-halo-2,4-dinitrobenzenes have been measured in several laboratories¹⁻⁴ and a comprehensive review of the subject of nucleophilic substitution reactions and their mechanism has been published by Bunnett⁵. Kruger and Bednova¹ showed that, although chlorine normally accelerates reaction, the acceleration was weaker when it was ortho- to an activating nitro group, when reactions of methoxide with 1-chloro-2,4-dinitrobenzene were studied. The de-activation was attributed to rotation of the nitro group, thus interfering with the partial conjugation of the C—N bond. Parker⁶, again investigating reactions of methoxide and 1-halo-2,4-dinitrobenzenes, observed these steric effects and found the order of de-activation to be $I > Br > Cl > F$, and suggested that this was due to the relative sizes of the halogen atoms causing varying angles of rotation of the ortho-nitro groups. As no direct measurements of the molecular dimensions of these molecules had been made, it was suggested by Dr. J. Miller, of the Department of Chemistry, University of Western Australia, that single-crystal X-ray diffraction structure analyses of the 1-halo-2,4-dinitrobenzenes be undertaken to measure accurately these angles of twist of the 2-nitro groups. Samples of the chloro-, bromo-, iodo- and fluoro-compounds were kindly provided by Dr. J. Miller for the investigation.

Preliminary studies of the compounds showed two of them, 1-chloro-2,4-dinitrobenzene and 1-bromo-2,4-dinitrobenzene, to be isomorphous, conforming to the orthorhombic space-group *Pcn* and having eight molecules in the unit cell. 1-iodo-2,4-dinitrobenzene crystallizes in a lower symmetry and 1-fluoro-2,4-dinitrobenzene is a liquid at room temperature.

The chloro- and bromo-compounds were chosen for initial detailed study. Their cell dimensions are:

Compound	a_0	b_0	c_0
1-Chloro-2,4-dinitrobenzene	8.937 Å.	11.035 Å.	15.675 Å.
1-Bromo-2,4-dinitrobenzene	8.898 Å.	11.244 Å.	15.753 Å.

Intensity data up to $\sin \theta/\lambda = 0.515$ for the $(0kl)$ and $(h0l)$ zones of both compounds were measured on a single-crystal Geiger counter spectrometer. These were extended to the full range of the sphere of reflexion for copper radiation by standard photographic techniques.

The heavy-atom co-ordinates were found from Patterson and difference Patterson syntheses projected on the (100) and (010) planes. The remaining atomic positions were located in Fourier syntheses on these planes, the signs of the Fourier coefficients being determined, initially, by the contribution of the heavy atom alone and then, later, by the combined contributions of the heavy atom and seven postulated light atoms.

The (100) and (010) projections of both compounds have been refined by successive difference syntheses and the 'reliability indices' for the calculated and observed structure factors are $R(0kl) = 0.137$ and $R(h0l) = 0.118$ for 1-chloro-2,4-dinitrobenzene and $R(0kl) = 0.097$ and $R(h0l) = 0.087$ for 1-bromo-2,4-dinitrobenzene.

As expected, the planes of the 2-nitro groups are rotated from the planes of the benzene rings, the measured angles being 39° for the chloro-compound and 40° for the bromo-compound. The proximity

of the 2-nitro groups and the heavy atoms in these compounds has also caused distortions of the heavy atoms from the positions collinear with the 1- and 4-carbon atoms of the benzene rings. Thus the C_1 -Hal bond is at about 5° to the line joining C_1 and C_4 .

In addition, the planes of the 4-nitro groups are rotated from the planes of the benzene rings. These twists (about 15°) are presumably due to field effects associated with the neighbouring molecules.

The average bond-lengths at the present stage of refinement are 1.20 Å. for the N—O bonds and 1.45 Å. for the C—N bonds.

Assumptions attributing chemical de-activation of these compounds to the rotation of the ortho-nitro groups out of the benzene ring planes have been found to be justified stereochemically. However, the conclusion of Parker⁶ regarding the relation of the relative twists of these groups and their de-activating powers has not been verified.

Although all the points of chemical interest in the structures have now been elucidated, evidence for thermal anisotropic motions of the heavy atoms and the atoms of the nitro groups has appeared in the difference maps. An analysis of these vibrations is in progress and a full report will shortly be published elsewhere.

During the course of these X-ray investigations a brief preliminary report of an investigation of the structure of 1-chloro-2,4-dinitrobenzene was published⁷, but the results of only one projection were given, and there was consequently no discussion of the chemical significance of the results.

Financial assistance provided by the Australian Atomic Energy Commission is gratefully acknowledged.

Magnetic Resonance of Protons in Glasses

We have been interested in the effect of sodium fluoride and calcium fluoride on molten silicates and phosphates, and the principal reactions are being investigated using kinetic and infra-red techniques. We have also been interested in the elimination of water from the melts by the fluorides and have used a proton magnetic resonance technique for studying the elimination. The infra-red technique has recently been used to investigate water elimination from silicate-glasses¹, but it would be difficult to obtain results using the same technique for glasses containing phosphate since these pick up water to a great extent and very quickly.

Sodium metaphosphate and potassium metaphosphate can be prepared by heating the sodium and

potassium dihydrogen phosphates respectively. The metaphosphates are produced from their respective acid salts by dehydration processes; hence to prepare these compounds containing water it is only necessary to heat the acid salts for a short time. The sodium metaphosphate glass and potassium Kurrol salt were prepared by heating the respective A.R. quality salts for 6 min. at 900° C. Similarly, borate-glass containing water was prepared by heating A.R. ortho-boric acid for 6 min. at 900° C.

Mixtures of sodium disilicate and sodium metaphosphate plus sodium disilicate and sodium pyrophosphate were saturated with water by heating the melts in a stream of steam at 1,000° C. for 8 hr. Carefully dried, analytical reagent quality sodium fluoride was added to each of these samples to give 10 weight per cent mixtures and the mixtures heated in attempts to eliminate the water.

Samples were quenched on a clean stainless steel plate and immediately crushed and weighed out in dry boxes maintained at 30–35 per cent relative humidity. 1-gm. samples were sealed in 'Pyrex' tubes which had been carefully dried at 400° C. for two to three days. During the sealing process, the 'Pyrex' tubes were connected to a drying tower containing phosphorus pentoxide, so the sample was not exposed to the air.

Proton resonances were observed using a Pound-Watkins marginal oscillator of conventional design operating at a fixed frequency of 21.750 Mc./s. The magnetic field was varied by connecting a motorized d.c. supply across field-bias coils wound around the poles of a permanent magnet. Tuning of the radio-frequency amplifier stage was employed to facilitate production of low oscillation-levels. The field was modulated at 280 c./s. and the output of the marginal oscillator passed through a phase-sensitive detector to give a derivative signal to a chart recorder.

The specimens were found to be easily saturated, and the resonance signals were therefore rather weak. Line-widths were about 4 crstedes, and a modulation amplitude of 1.5 crstedes was found to give optimum signal-to-noise ratio. The oscillation amplitude was maintained at a constant level corresponding to about 100 mV. across the specimen coil. A 5-sec. time-constant filter was used in the output stage of the phase-sensitive detector.

The signal strength was taken as the distance between maximum displacements of the derivative curve. It was estimated that any water content exceeding $\frac{1}{2}$ per cent would give a resonance signal detectable with this apparatus.

In the sodium metaphosphate series, samples of the glass were heated for 5, 10 and 20 min. with sodium fluoride. The proton signals are shown in Fig. 1 and it can be seen that the water, which is bonded in the lattice, is eliminated.

Similarly, water is eliminated by sodium fluoride from potassium Kurrol's salt, boron trioxide and the disilicate-metaphosphate mixture containing 15 per cent phosphorus pentoxide.

Further, an estimate of the accuracy of the determination of the number of protons by the resonance method was made by preparing two samples of boron trioxide in which the water content can be determined by titration³. The ratio of water contents in the samples by direct titration and the ratio of signal-to-noise ratio for the two samples are 3.4/2.8 and 8.3/6.5 respectively. We have also located

Fig. 1. (a) Proton resonance at 21.750 Mc./s. due to water in sodium metaphosphate glass. (b) Proton resonance at 21.750 Mc./s. in the same sodium metaphosphate glass after being heated at 900° C. for 5 min. with dry A.R. quality sodium fluoride

proton resonance peaks in the other phosphate-silicate mixtures prepared.

Attempts to use the fluorine-19 chemical shift to determine the amount of P-F and Si-F bonding in the various samples were unsuccessful.

These results will be reported in more detail later.

Atomic Polarizations of Chloro-, Bromo- and Iodo-benzene

In 1940, Bottcher¹ suggested that the distortion polarization of a compound such as mono-chlorobenzene might be obtained by assuming it to be the mean of the total polarization for the parent compound, benzene, and for *p*-dichlorobenzene.

Dielectric constant and density measurements on benzene, chlorobenzene, *p*-dichlorobenzene, bromobenzene, *p*-dibromobenzene, iodobenzene and *p*-diiodobenzene, using carbon tetrachloride as solvent at 25°, have been made and the distortion polarizations of chloro-, bromo- and iodo-benzene calculated.

The atomic polarizations obtained by subtracting the electronic polarizations (R_D) from the distortion polarizations (P_D) determined in this manner are given in Table 1 under the heading P_A (exp.).

Compound	Table 1		
	P_A (exp.) (c.c.)	P_A (calc.)	0.05 R_D
Chlorobenzene	3.7 ± 0.4	2.8	1.6
Bromobenzene	2.5 ± 0.5	2.1	1.7
Iodobenzene	2.4 ± 0.7	1.8	2.0

The respective in-plane and out-of-plane bending frequencies (ν) for the mono-halogenobenzenes, as assigned by Pyler², have been substituted into an equation for a much simplified model of a halobenzene molecule. For this model the halogen

atom (X) is regarded as the 'bob' of a simple pendulum of length r , equal to the (aromatic) $C-X$ distance; the bending force constants for the two bending modes is calculated from $k_B = 4\pi^2\nu^2m_x$. When such values of k_B are substituted into the equation $P_A = (4\pi N\mu^2/3k_B)$ and these P_A values are added to the atomic polarization figure for benzene (1.6 c.c.), the P_A (calc.) figures listed in Table 1 are obtained.

Also listed in Table 1 are the estimates often used for the atomic polarizations, namely, that they are 5 per cent of the electronic polarizations.

Bottoher's method, when applied to the three mono-halogenobenzenes, gives values for the atomic polarizations of these molecules, which are in qualitative agreement with rough application of theory. Further, it indicates a decrease in atomic polarization with increasing mass of substituent in the series chloro-, bromo-, iodo-benzene, thus lending support to the idea⁴ that atomic polarization cannot be assumed to be a fixed fraction of the electronic polarization of a molecule.

Details of this work will be published elsewhere.

Ionic Conductances in Gels of Wheat Starch

POLYMERIC gel systems may be formed either by cooling a polymer solution, or by swelling a suspension of solid polymer particles in a suitable solvent. These two types of gelation process differ in one fundamental respect. Gel formation from solution is usually a thermoreversible process, and on warming, the system reverts back to a solution. On the other hand, gelation by swelling is thermally irreversible, and scarcely any shrinkage occurs on cooling.

Starch gelation in water is a typically irreversible process. Above 55°, granules of wheat starch swell irreversibly. On cooling, molecules from adjacent granules link up by hydrogen bonding and molecular entanglement to form a continuous network of swollen starch granules.

There is evidence in the literature^{1,2} that gel formation from solution occurs with little or no change in the conductance of electrolyte present. This means that the water has a micro-viscosity similar to that of normal free water, although of course the bulk viscosity of the gel is considerably greater. However, it has previously been shown from the nuclear magnetic resonance spectra³ that starch gelation has a very marked effect on the water structure. These changes should be reflected in the conductance, and it was therefore decided to study the conductance changes of sodium chloride in a number of starch-water mixtures during gelation. Conductivity measurements were made using a pair of platinum disk electrodes. The mixtures were heated slowly from 25° to 85° and afterwards cooled back to 25° again. During the early period of heating

Fig. 1. Conductance of 0.412 per cent sodium chloride in 37 per cent starch

the system consisted of two phases, and the suspension was agitated before readings were taken. Above 55° gelation took place and the electrodes became firmly embedded.

Provided there was sufficient starch (12 per cent) to form a coherent gel, the conductances were always lower in the gel than in the suspension as expected. A typical example is shown (Fig. 1) in which the changes can be conveniently divided into three portions.

(1) The suspension AB before gelation has started. During this stage the changes in conductance are thermally reversible.

(2) The process of gelation BC during which the conductance falls. Gelation is an irreversible process and the line CB cannot be retraced if the system is cooled. On cooling from a point on BC , the conductance values fall on a line intermediate between AB and EC .

(3) The fully gelatinized system EOD . Gelation is complete at C and the conductivity starts to rise again with increasing temperature. The conductance is now thermally reversible, and on heating or cooling, the conductance values will always lie on the same curve EOD .

These changes in conductance can be correlated with the swelling behaviour of wheat starch. At 25° water is absorbed into the amorphous regions, and the granules swell about 30 per cent by volume⁴. Little further swelling occurs until about 55° when the granules suddenly begin to swell rapidly with increasing temperature⁴. This is the point B where the gel is first formed, at high starch concentration. The process of swelling and particle adhesion continues for about another 15°, the maximum swelling (at O) being governed by the amount of water available.

Having established the general pattern of behaviour, some more precise conductance (χ) measurements were made on suspensions and gels containing 37 per cent starch and varying amounts of sodium chloride, at 25° and 50°. Corrections for ionic

Fig. 2. Variation of R_{25} with starch concentration

impurity in the starch were made, by subtracting the values obtained during a blank experiment done in the absence of any added sodium chloride. The corrected results are given in Table 1 and Fig. 2.

It was found that $\frac{1}{\chi} \frac{\Delta\chi}{\Delta T}$ (and consequently the energy of activation for ionic mobility) over this temperature-range was 1.7 times greater in the gel than in suspension. This is in qualitative agreement with the increase in the micro-viscosity of the water after gelation, which has previously been established from the water proton line in the nuclear magnetic resonance spectra. The band-width of this line was found to increase on gelation, and there was no 'free' water line superimposed on the broader line. Therefore, all the water in the gel is in a more highly bound state, leaving no fibrils of free water, contrary to what has been postulated for some other gel systems.

The variation of the conductance behaviour with starch concentration follows a pattern similar to the variation of nuclear magnetic resonance water band-width. The ratio of conductance of sodium chloride in suspension and gel at 25° (R_{25}) increases almost linearly from 1.0 at 12 per cent to 1.6 at 37 per cent starch, showing that the water becomes increasingly bound as the starch concentration is increased above 12 per cent. Similarly the water proton line in the nuclear magnetic resonance spectra resembles that of

pure water in swollen starch mixtures up to about 12 per cent concentration, but at higher concentrations the band-width increases. The similarity between these two sets of results suggests that the change in the water structure on gelation is the main factor contributing to the fall in conductance.

There may also be other factors. For example, it is possible that the ions do not penetrate into the granules, in which case the tortuous migration of ionic particles around the swollen granules would tend to reduce the conductance. However, it is known that some large molecules, for example the dye congo red, are easily absorbed by swollen granules even in the cold, and it therefore seems likely that sodium chloride penetrates into the granules. This is supported by the fact that swelling causes no detectable drop in conductance ($R = 1$) at starch concentrations just below the minimum starch concentration (12 per cent) for gel formation, where the swollen granules occupy about 50 per cent of the total volume.

It seems likely that these unusual conductance results are due primarily to the change in water structure. If this is so, the ratio R_{25} should be a rough measure of the micro-viscosity of the water in the gel, since the conductivity is approximately inversely proportional to the viscosity of the medium.

The increase in micro-viscosity on gelation has, on the basis of the nuclear magnetic resonance results, previously been attributed partly to the formation of a four co-ordinated water lattice around each starch hydroxyl group, and partly to the 'fixing' of these regions of solvated water, by the formation of a continuous polymer network on gelation. Both these factors become more marked at higher starch concentrations; this is reflected in the increase in R_{25} . It is worth pointing out that gelatin, which is itself ionic, shows no fall in conductance on gelation¹. This is probably because gelatin has a smaller effect on the water structure due to its lower hydrogen bonding power and also because the polymer concentrations are lower in these gels. The anomalous behaviour of starch is due to its high degree of hydrogen bonding power, which has a marked effect on the water structure and also enables the starch to form a strong polymer network.

BIOCHEMISTRY

Structure of Isometamidium (M. and B. 4180A), 7-m-Amidinophenyldiazoamino-2-amino-10-ethyl-9-phenylphenanthridinium Chloride Hydrochloride, the Red Isomer present in Metamidium

THE trypanocidal drug, metamidium, first described by Wragg, Washbourn, Brown and Hill¹, was obtained from the coupling reaction between *m*-amidinobenzenediazonium chloride and homidium chloride. It was isolated as a mixture of purple and red compounds (55 and 45 per cent, respectively) which were

Table 1. CONDUCTANCE OF SODIUM CHLORIDE IN 37 PER CENT STARCH
Sodium chloride (per cent)

	0.206 per cent	0.412 per cent	0.824 per cent	1.647 per cent
R_{25}	1.64	1.82	1.51	1.50
C_g	0.026	0.030	0.028	0.027
C_s	0.016	0.015	0.016	0.016
C_g/C_s	1.6	2.0	1.75	1.7

$$R_{25} = \frac{\text{Sodium chloride conductance in suspension at 25°}}{\text{Sodium chloride conductance in gel at 25°}}$$

$$C_g = \frac{1}{\chi} \frac{\Delta\chi}{\Delta T} \text{ for gel between 25° and 50°.}$$

$$C_s = \frac{1}{\chi} \frac{\Delta\chi}{\Delta T} \text{ for suspension between 25° and 50°.}$$

separated by fractional crystallization and shown to be isomeric. The red (M. and B. 4180A) was more active than the purple isomer, both therapeutically and prophylactically, against a laboratory strain of *Trypanosoma congolense* in mice. Wragg *et al.*¹, on the evidence available at the time, provisionally assigned diazoamino structures to these two isomers, and stated that work to verify these was being done. Several unsuccessful attempts were at first made to determine the structure of the red compound, and this has now been achieved by deamination which gave the desamino compound (I), which was identical in analysis, properties, and infra-red spectra with authentic specimens of (I) prepared by: (a) the coupling reaction of diazotized 7-amino-10-ethyl-9-phenylphenanthridinium chloride with *m*-amino-benzamidine, and (b) the coupling reaction of 7-amino-10-ethyl-9-phenylphenanthridinium chloride with *m*-amidinobenzene diazonium chloride.

The evolution of nitrogen which occurred when the red and purple compounds were heated with 6 *N* sulphuric acid was given as evidence for the presence of a diazoamino group in both compounds (Wragg *et al.*¹), although it was pointed out by these workers that for unexplained reasons the purple isomer gave considerably less than the theoretical volume of nitrogen. Further work has now shown that these reaction conditions were too drastic for a diagnostic test for the presence of a diazoamino group as distinct from an aminoazo system, and milder conditions will clearly differentiate the two systems. Thus, if the red compound (isometamidium) is heated with cuprous chloride-3 *N* hydrochloric acid, the theoretical quantity of nitrogen is evolved in 7-9 min., while no evolution of nitrogen occurs even after prolonged heating of the purple compound under identical conditions. Thus only the red compound contains a diazoamino-group. Recent investigations into the structure of the purple compound have revealed that it is an isomeric aminoazo compound.

As a result of this work, the formulae provisionally suggested for the two isomers by Wragg *et al.*¹ have to be modified, and the red isomer is now shown to have structure (II) (which was originally assigned to the purple compound).

Concurrently with this investigation the original coupling reaction has been studied and conditions² have been established under which isometamidium (II) is the main product formed, the ratio of red:purple compound being as high as 9:1 (polarographic

determinations carried out by Dr. P. O. Kane), and the pure product is readily isolated, by standard procedures, from the reaction mixture.

The trypanocidal activity of isometamidium (M. and B. 4180A) has been confirmed in cattle, and the results of field trials in Africa are very encouraging.

Full details of the chemical work involved in the proof of the structure of isometamidium and of the modified coupling reaction will be submitted in due course to the *Journal of the Chemical Society*.

I am grateful to Dr. H. J. Barber, Dr. J. N. Ashley and colleagues of this research organization for their discussions and helpful advice.

1,3-Dialkyl-6-thioxanthines: a New Series of Bronchodilators and Coronary Vasodilators

1,3-DIMETHYLXANTHINE (theophylline) is readily converted into the corresponding 6-thio derivative by treatment with phosphorus pentasulphide in pyridine. The choline salt (M. and B. 4926A) of this derivative is more active than choline theophyllinate in relaxing the bronchial muscle (guinea pig tracheal ring preparation) and in dilating the coronary vessels (dog heart-lung preparation). This result led us to prepare and examine a series of homologous compounds, the most active in these two respects being 3-isobutyl-1-methyl-6-thioxanthine (M. and B. 5924).

All the thioxanthines are obtained from the corresponding xanthines in high yield by refluxing for several hours with phosphorus pentasulphide in pyridine. It was established by spectroscopic and degradation studies that thionation occurs only in the 6-position.

The choline salt of 3-isobutyl-1-methyl-6-thioxanthine is a pale yellow, crystalline solid, m.p. 145-147°, which is more than 50 per cent w/v soluble in water at 20°. A 10 per cent w/v solution has a pH of 11. Choline 6-thiotheophyllinate, m.p. 146-149°, has similar solubility characteristics.

Pharmacologically the 6-thioxanthines are very similar to theophylline, the difference in their actions being essentially quantitative. Some of the 6-thioxanthines are very much more active as bronchodilators *in vitro*, M. and B. 5924 being about sixty times as active as choline theophyllinate. *In vivo* bronchodilator activity was assessed by determining whether pretreatment would protect guinea pigs against the lethal effects of a bronchoconstrictor aerosol. The 6-thioxanthines are effective, but the relative bronchodilator activity is much less than that observed with the isolated preparation. The 3-isobutyl-1-methyl derivative is also more active than choline theophyllinate in dilating the coronary vessels of the dog heart-lung preparation, in dilating the coronary vessels of the anesthetized dog and in dilating the vessels of the hind leg of the dog perfused with heparinized blood. As diuretics, however, all the thioxanthines are less potent than choline theophyllinate. Comparative results are summarized in Table 1.

Table 1. RELATIVE ACTIVITIES OF CHOLINE THEOPHYLLINATE, CHOLINE THIOTHEOPHYLLINATE AND M. AND B. 5924 (The activity of choline theophyllinate has been expressed arbitrarily as 1)

Compound	Bronchodilator activity (guinea pig)		Coronary dilator activity (dog)	Diuretic activity (rat)
	<i>In vitro</i>	<i>In vivo</i>		
Choline theophyllinate	1	1	1	1
Choline thiotheophyllinate	5	1	2-8	< 1
M. and B. 5924	60	2	15	< 1

A full description of the chemical work will be submitted to the *Journal of the Chemical Society* and of the pharmacological work to the *British Journal of Pharmacology and Chemotherapy*.

Ayapin, Scopoletin and 6,7-Dimethoxycoumarin from *Dendrobium thyrsiflorum* (Reichb. f.)

DURING the examination of plants for phenolic constituents, the orchid *Dendrobium thyrsiflorum* was found to contain three highly fluorescent constituents (E. C. Bate-Smith, personal communication). The substances were extracted from a leaf hydrolysate with amyl alcohol and chromatographed on Whatman No. 1 paper using several different solvent systems. All the substances concerned fluoresce strongly a light blue-violet colour which is changed to green when the paper is sprayed with 2 N sodium hydroxide. The R_F values in toluene/acetic acid/water (supernatant phase from 4 : 1 : 5 vol.) were 0.15, 0.77 and 0.85 and in 6 per cent acetic acid 0.43, 0.54 and 0.61. In Forestal solvent (hydrochloric acid/acetic acid/water) and butanol/acetic acid/water the R_F values were all too high to give good separation.

The reaction with sodium hydroxide strongly resembled that given by coumarin (R_F in toluene-acetic acid 0.9). The first substance, in fact, agreed in every respect with the well-known coumarin scopoletin. The other two substances, from their R_F values relative to those of scopoletin and coumarin, seemed likely to be polymethoxy- or methylenedioxy-coumarins. Samples of ayapin (6,7-methylenedioxy-coumarin) and 6,7-dimethoxycoumarin were therefore synthesized, and a sample of the latter and also of 5,6,7-trimethoxycoumarin were obtained from Dr. F. E. King. The dimethoxycoumarin agreed in all particulars with the second unknown substance and ayapin with the third. Trimethoxycoumarin has virtually the same R_F as ayapin in toluene/acetic acid/water but its R_F value in 6 per cent acetic acid is much higher (0.76), and when the paper is sprayed with alkali its fluorescence changes to bright yellow-white. The hydrolysate was chromatographed on Whatman No. 3 paper in 6 per cent acetic acid, the three substances were eluted, and their ultra-violet absorption spectra compared with synthetic standards. All showed closely similar spectra with maxima at 345 m μ and 295 m μ , a shoulder at 260 m μ and minima at 270 m μ and 305 m μ . Since the absorption spectra are quite different from other related coumarins such as

herniarin, daphnetin, limetin, it is concluded that 6,7-dimethoxycoumarin and ayapin are the substances present.

In order to determine the form in which these substances occur in the plant, an extract of a leaf was made with cold methanol. This was run on Whatman No. 3 paper in 6 per cent acetic acid. No free coumarins were present, but there were three distinct fluorescent bands which were cut out and eluted. On hydrolysis the slowest-running of these gave the dimethoxycoumarin, the second gave ayapin and the third gave a mixture of these two and scopoletin. It is concluded that these coumarins occur in combination, probably as the glycosides of the corresponding o-coumaric acids, and that the dimethoxycoumarin and ayapin both occur in more than one glycosidic form.

I wish to thank Dr. F. E. King for the specimens of dimethoxy- and trimethoxy-coumarins and Dr. E. C. Bate-Smith for helpful advice and the facilities of his laboratory.

Reserpine Analogues

It seems likely that the most interesting pharmacological properties of the natural alkaloid reserpine are mainly determined by three chemical groups in the molecule: (1) the β -indolylethylamine group, which is present in many other natural drugs (serotonin, ergot alkaloids); (2) a tertiary nitrogen atom which is substituted by three carbon chains, one of which (the ethyl group) is attached to the indole nucleus, while the other two form part of a ring system bearing (3) a hydroxyl group which is esterified by trimethoxybenzoic acid. The β -phenylethylamine group, which is very similar to the β -indolylethylamine group, is found in another group of drugs, the adrenaline family.

On the basis of these considerations we have synthesized a number of compounds the structure of which is more or less similar to that of reserpine, in the hope that these would have useful medicinal properties. These compounds fall into two classes: β -indolylethylamine derivatives, having the general formula I:

where R indicates the absence of substitution, or substitution by one or two hydroxyl or alkoxy groups, and R_1 and R_2 are alkyl or hydroxy-alkyl groups which may be etherized or esterified; and β -phenylethylamine derivatives, II:

where R indicates the absence of substitution, or substitution by one to three hydroxyl or alkoxy

groups, R_1 is H or OH, R_2 , R_3 and R_4 are H, alkyl or alkylene groups, which may be partly cyclized to give piperidyl and cyclohexyl rings, as in reserpine, and R_5 is an alkoxybenzoyl group.

We tested all these compounds for adrenolytic and spasmolytic activity, and for their effect on the central nervous system, the heart and the circulation, with the following results.

β -Indolylethylamine derivatives. Some of these show properties which are very similar to those of reserpine: they potentiate hexobarbital and ether narcosis in mice, like reserpine but to a lesser extent, and show a tranquillizing effect on the same animals. Some of these compounds also have a hypotensive effect on rats and dogs, and produce bradycardia in dogs.

β -Phenylethylamine derivatives. Unlike reserpine, these compounds have little or no effect on the central nervous system.

Those compounds in which the phenyl group is substituted by alkoxy groups produce spasmolysis and bradycardia; two compounds of this group, with $R = p\text{-OCH}_3$, $R_1 = \text{H}$, $R_2 = \text{CH}_3$, $R_3 = \text{C}_2\text{H}_5$, $R_4 = -(\text{CH}_2)_4-$ and $R_5 = 3,4,5\text{-trimethoxybenzoyl}$ or $3,4\text{-dimethoxybenzoyl}$, show a strong papaverine-like spasmolytic effect, and also atropine-like properties. The other effects are considerably weakened.

Where the phenyl group is unsubstituted or substituted by hydroxyl groups (p - or m,p -), on the other hand, the depressor and adrenolytic activities predominate. Two such compounds, with $R = \text{H}$, $R_1 = \text{H}$, $R_2 = \text{H}$, $R_3 = \text{C}_2\text{H}_5$, $R_4 = -(\text{CH}_2)_3-$ or $-(\text{CH}_2)_4\text{CH}-$ and $R_5 = 3,4,5\text{-trimethoxybenzoyl}$,

cause a depressor effect of long duration in narcotized cats. This effect begins instantaneously and is accompanied by a slight degree of bradycardia.

Clinical investigations are in progress. The chemical synthesis of these compounds and the pharmacological investigations will be described elsewhere.

Effects of Short-term Weaning on the Acid-soluble Ribonucleotides of Rat Mammary Gland

THE physiological and biochemical changes which occur during early involution in the mammary gland are of great complexity; the gland regresses from a highly active secretory tissue to one in which the

metabolic activity is greatly diminished. The ribonucleic acid and total protein content¹ has been reported to have decreased at two days of involution as does the activity of many enzyme systems². Evidence is presented in this communication that marked changes occur in the acid-soluble ribonucleotides over as short a period of weaning as 12 hr.

Primiparous lactating rats of an albino strain were taken between the seventeenth to nineteenth day of lactation. The pups were removed from the mother at 9 a.m. except in experiments of 12 hr. weaning when the pups were removed at 9 p.m. Rats were killed by dislocation of the cervical vertebrae and the mammary glands were excised rapidly and put into liquid nitrogen. The acid-soluble ribonucleotides were extracted and examined by gradient elution on a 'Dowex-1' (formate form) column by essentially the method described by Hurlbert *et al.*³

The chromatogram obtained for the whole gland before weaning and after 12 hr. of weaning are shown in Figs. 1 and 2.

Figs. 1 and 2. Chromatograms of acid-soluble ribonucleotides extracted from the mammary gland of a late lactating rat before involution and after 12 hr. weaning, respectively. The nucleotides were eluted by the gradient elution method described by Hurlbert *et al.* (ref. 3) with three changes of solvent, as shown, from 'Dowex-1' (formate form) ion-exchange columns and collected in 5 ml. fractions. In top chromatogram the optical absorptions greater than 1.0 for adenosine monophosphate were 1.8, 1.8, 1.5 for each 5 ml. fraction; in bottom chromatogram the figures were 1.8, 2.8, 2.8, 1.8 for each 5 ml. fraction.

Abbreviations: C, Cytidine; A, adenosine; U, uridine; G, guanosine; MP, DP and TP, mono-, di- and tri-phosphate, respectively; X, N-acetylglucosamine; X₂, glucose; DPN, diphosphopyridine nucleotide; F-A, formic acid; AM-F, ammonium formate.

On comparison of these two chromatograms it will be noticed that there is a striking decrease in the content of adenosine di- and tri-phosphates, with a correspondingly large increase in the adenosine monophosphate. This dephosphorylation seems to be general for the other nucleoside phosphates, although the uridine diphosphate complexes of acetylglucosamine and glucose are unaffected. Since the adenosine phosphates are most abundant the time course of this dephosphorylation was followed by plotting the time of weaning against the ratios of adenosine di- and tri-phosphates to adenosine monophosphate. It should be borne in mind that adenosine triphosphate is not present as a pure fraction in the chromatogram but contains other nucleotides, uridine diphosphate being the main one. This fraction at late lactation normally contains about 65 per cent adenosine triphosphate⁴.

Table 1

Animals used in experiment	Hours of weaning	Total acid-soluble ribonucleotide (μ moles/gland)
2	0	16.7
1	2	14.5
1	4	10.2
1	6	10.5
1	8	15.5
2	12	13.5
	Hours of lactation after 12-hr weaning	
2	2	20.5
1	4	14.7
		Mean = 14.5 S.E.M. = 1.09

Fig. 3 shows these ratios decrease slightly up to about the sixth hour, after which they fall rapidly to the eighth hour; from here the low values attained are constant. When lactation is restarted after 12 hr. weaning, by the re-introduction of the pups, the ratios can be seen to rise steeply, the normal lactating values being reached by 2 hr. After 4 hr. of suckling these values are still obtained. This indicates that the phenomenon is unlikely to be wholly due to diurnal variations and that even after 12 hr. weaning the dephosphorylation of adenosine di- and tri-phosphates can be reversed. Another point which emerges (see Table 1) is the constancy of the total acid-soluble ribonucleotide content of the gland throughout all the experiments undertaken. This would suggest that the catabolism of the nucleotides is not enhanced by the weaning period of 12 hr.

It has been reported by Turner⁵ that weaning affects the fat composition of milk; longer periods of weaning giving rise to a lower fat content of the milk. It has been suggested that the cause is the retention by the mammary cells of fat components due to the high pressure developed in the mammary gland during weaning while the more permeable components are secreted into the alveoli of the mammary gland.

The presence of alkaline phosphatase in milk has been reported by Morton⁶, and, although its function is not clearly understood, there seems little doubt that it originates in the alveolar cells of the mammary gland. It is conceivable that weaning would lead to a complete or partial retention of alkaline phosphatase in the same manner as occurs with fat under similar conditions. Such a retention would render the acid-soluble ribonucleotides vulnerable to enzymic dephosphorylation.

Fig. 3. Time course of dephosphorylation of adenosine polyphosphates. ■, Ratio of adenosine di- to mono-phosphate; ●, ratio of adenosine tri- to mono-phosphate

Further support for this suggestion of retention by the cell of phosphatases comes from the observed rise in pressure during weaning. Tgetgel⁷ has shown that in the cow pressure in the udder increases slowly up to about the fourth hour and thereafter rapidly. Assuming a similar type of pressure curve in the rat mammary gland the drop in the ratios of adenosine triphosphate and diphosphate to monophosphate mirrors remarkably this increase.

Since adenosine di- and tri-phosphates are known to play an important part in many biosynthetic reactions which are active in the lactating mammary gland, it is possible then that the levels of the mono-, di- and tri-phosphorylated nucleosides could govern the rates of biosyntheses. Thus the rate of milk production of the rat mammary gland may be maintained by a 'feed-back' mechanism involving an increasing phosphatase activity in the cell coupled to an increasing accumulation of milk in the mammary gland.

My thanks are expressed to Drs. A. L. Greenbaum, and T. F. Slater for their guidance and helpful criticism. This work was made possible by a Medical Research Council Studentship award.

Reduction of α -Ketobutyrate by Human Serum

DURING the course of investigations into serum transaminase activities¹, it was observed that α -ketobutyrate (2-oxobutanoate) underwent enzymic reduction in the presence of serum and reduced diphosphopyridine nucleotide. At the time this was interpreted as being due to serum lactic dehydrogenase because a commercial sample of crystalline lactic dehydrogenase prepared from rabbit skeletal muscle reduced α -ketobutyrate almost as readily as its normal substrate, pyruvate². Further work, however, has indicated differences between the action of serum on α -ketobutyrate and its action on pyruvate.

Dehydrogenase activities were measured spectrophotometrically at 340 m μ in 0.067 M Sørensen phosphate buffer at pH 7.4 (ref. 3). Temperature corrections were applied and all results were adjusted to 25°. The results of a typical experiment on the effect of variation of substrate concentration on the dehydrogenase activity of normal human serum is shown in Fig. 1. Maximum activity against pyruvate occurred when the substrate concentration was 0.33×10^{-3} M and at higher concentrations appreciable substrate inhibition occurred. When α -ketobutyrate was used, activity was maximal at a concentration of 3.3×10^{-3} M. The Michaelis constants calculated from these were $K_m = 1.0 \times 10^{-4}$ for pyruvate and 6.7×10^{-4} for α -ketobutyrate. These figures are of comparative value only since no account has been taken of the presence in serum of possible inhibitors.

Fig. 1. Effect of changes in substrate concentration on the dehydrogenase activity of serum against pyruvate (O) and α -ketobutyrate (●).

but repetition of the experiment with other normal sera gave similar curves.

The effect of pH variation was measured using optimal substrate concentrations and the results appear in Fig. 2. The activity against α -ketobutyrate was maximal at pH 7.4 and was appreciably less at pH 8.0 whereas that against pyruvate was increased at the higher pH value.

Fig. 2. Effect of pH variation on the dehydrogenase activity of serum against pyruvate (O) and α -ketobutyrate (●).

Over the range 21–28°, the temperature coefficient was found to be linear in both cases, but was slightly greater for pyruvate (8 per cent/deg. C.) than for α -ketobutyrate (6 per cent/deg. C.).

No inhibition of enzymic activity by a final concentration of 1.67×10^{-3} M azide, fluoride, cyanide, iodoacetate, sequestrate or oxine was observed, but 6.87×10^{-3} M cyanide reduced the activity against both substrates to a similar extent.

Four normal sera were fractionated by means of continuous paper electrophoresis using barbitone buffer of pH 8.6 ($\mu = 0.05$). Lactic dehydrogenase activity was detected in the α_1 , α_2 , β - and γ -globulin fractions. The enzyme present in the β - and γ -globulin fractions, however, was much more active against pyruvate than against α -ketobutyrate whereas that in the α -globulin fractions showed only slightly greater activity against pyruvate (Fig. 3).

The dehydrogenase activities of a number of normal and pathological sera were examined. The ratio of the activities against pyruvate and α -ketobutyrate was found to vary between 1.4:1 and 1.1 to 1, figures well outside the limits of experimental error.

The differences in temperature coefficients, Michaelis constants and pH optima shown by serum towards the two substrates could possibly be explained by the effect of substrate variation on a single enzyme system. This is unlikely since serum lactic dehydrogenase has been shown to be electrophoretic-

Fig. 3. Percentage differences in the dehydrogenase activity of electrophoretic fractions of human sera towards pyruvate and α -ketobutyrate. 2 ml. serum was separated into 12 fractions which were assayed separately for enzyme activity. Each point represents the mean percentage difference in the activities against these substrates exhibited by four different sera. Differences were not included when the total activity was less than 0.20 μ mole/hr.

ally heterogeneous⁴⁻⁷, and we have demonstrated that, although each globulin fraction exhibits activity against both pyruvate and α -ketobutyrate, the relative activities in each fraction are not parallel. It is therefore suggested that this variation indicates a difference in the properties of the components of serum lactic dehydrogenase or that there exists in serum an enzyme other than lactic dehydrogenase capable of reducing α -ketobutyrate.

Composition of the Free Fatty Acid Fraction in the Plasma of Human Arterial Blood

THE importance of free fatty acids as the main form in which fat is mobilized from depots and extracted by tissues has been stressed during the past few years. Several methods for their estimation in plasma are now available. One of the most widely used is that of Gordon *et al.*¹, which seems to measure the long-chain fatty acids² more specifically than any other. The exact composition of the fatty acids which are extracted from human plasma by this method has not, however, been determined. Their composition is of importance in metabolic studies where a knowledge of the mean molecular weight, double-bond index, and oxygen equivalent may be required.

We have analysed the free fatty acids extracted from the plasma of arterial blood by Gordon's method in eleven people who had fasted overnight. After titration, the soaps of the fatty acids in the alkaline ethanol-water phase were reconverted into free fatty acids which were methylated by means of diazo-

methane. The methyl esters were then diluted in diethyl ether and analysed in a Pye argon chromatograph. Polyvinyl acetate was used as the stationary phase, supported on 'Celite' (100-120 mesh). This stationary phase gave a separation at least as good as polyethylene glycol adipate and it had the further advantage of easier preparation and greater stability in the operating temperature (160-165°C.). The identification of the chromatograph peaks was made by using pure standards, supplemented by the method described by F. P. Woodford and C. M. Van Cent³. The area of each peak was measured by the triangulation procedure.

The main constituents are listed in Table 1. They are expressed as percentages of the total area of the major peaks. Oleic acid accounted for almost half. Apart from these major components, small traces of other fatty acids were found. These appeared to consist of *n*-nonanoic (pelargonic), decanoic (capric), pentadecanoic (15:0) and heptadecanoic (margaric) acids. Branched-chain fatty acids were also found as branched 14:0, 15:0, 16:0 and 18:0. The double-bond index⁴ was 24.41 ± 3.7 (mean $\pm$ S.D.). The mean molecular weight was found to be 270.8, which is lower than it has previously been assumed. The mean number of oxygen molecules required for complete oxidation of one equivalent of fatty acid found during titration was calculated to be 24.32.

Table 1

Fatty acids	Mean (per cent) S.D.
Lauric (12:0)	0.62 $\pm$ 0.16
Myristic (14:0)	3.91 $\pm$ 1.87
Myristoleic (14:1)	0.70 $\pm$ 0.34
Palmitic (16:0)	25.12 $\pm$ 1.51
Palmitoleic (16:1)	7.52 $\pm$ 2.14
Stearic (18:0)	9.43 $\pm$ 2.83
Oleic (18:1)	45.54 $\pm$ 4.42
Linoleic (18:2)	7.04 $\pm$ 1.59

The results are different from those obtained by Dole *et al.*⁴, who used Dole's method of extraction⁴ of free fatty acids from plasma of human venous blood. The chief difference is in the percentage of oleic acid present, which Dole *et al.* found to be 28.9 per cent, and in the double-bond index which they found to be 28.

These differences may be due to variations in the diet of the subjects studied. Theoretically they could also be due to changes which might occur between arterial and venous blood. Work which is being carried out in this laboratory, however, suggests that the changes in composition of free fatty acids during the passage of blood through a resting limb are very small. It seems likely, therefore, that the composition of the free fatty acids extracted depends on the method used.

We are grateful to Dr. S. Paul and Mr. T. D. Heyes of the Research Department, Lever Bros., Ltd., for technical advice and for providing us with pure standards of fatty acids

A New Cyclic Dipeptide from Peptone

WHILE investigating the antifungal principle derived from cultures of a *Bacillus subtilis* strain, a crystalline substance was obtained as one of the by-products. It was necessary to decide whether the crystals were a metabolite of the organism or originally contained in peptone used as a dietary essential. The same procedure succeeded in isolating the same crystals from peptone. The peptone was commercially available as 'Mikuni peptone' in Japan.

Purification was effected by recrystallization from a benzene-petroleum ether mixture. The crystals, purified as colourless needles, melted at 159.5° and was readily soluble in alcohols, chloroform and benzene and insoluble in water, ether and hydrocarbons. Carbon-hydrogen and nitrogen analysis and molecular weight measurement by Rast's method indicated molecular formula of $C_{11}H_{16}N_2O_5$. The infra-red spectrum showed absorption at 3,260 cm., 1,670 cm. and 1,630 cm., but no absorption of the 1,550-cm. region, which is characteristic of a cyclic amide. Significant optical rotation in methanol solution was observed as $[\alpha]_D^{25} = -132.8^\circ$. Hydrolysis with 6 *N* hydrochloric acid in a sealed tube at 110° for 20 hr. produced amino-acids. Qualitative analysis for the amino-acids by paper chromatography indicated equimolecular quantities of proline and leucine. All the results are in agreement for a cyclic dipeptide composed of two parts, proline and leucine.

It is perhaps of some interest that one of the 2,5-piperazinediones is contained in a natural substance, although certain proof of its original existence in raw meat evidently needs further investigation.

Work on the biological activity of the peptide is being carried on in several organisms.

We are grateful to Dr. Ichiji Mibuchi, Shizuoka College of Pharmacy, for discussion.

Stabilization of Thymidylate Kinase Activity by Thymidylate and by Thymidine

WE have recently reported that an increase in thymidylate kinase activity occurs in rat liver and kidney following injection of thymidine into the intact animal¹. Subsequent work has revealed that this enzyme activity is labile in the absence of, but stable in the presence of, thymidylate or thymidine. In this communication we wish to report the results of this work on stabilization of thymidylate kinase activity, and to consider the possible relation of these observations to the increase in kinase activity which follows thymidine administration.

Liver and thymus were removed from 200-300 gm. male Wistar rats, which were killed by decapitation. Regenerating liver was obtained from rats subjected

to 70 per cent hepatectomy³ under ether anaesthesia 48 hr. earlier. Frozen calf thymus was obtained from commercial sources. Tissue extracts were prepared by grinding in an all-glass homogenizer 200 mgm. of acetone powder³ with 2 ml. of ice-cold 0.1 M *tris*-(hydroxymethyl)aminomethane (*tris*) buffer, pH 7.5, or 1 gm. of fresh tissue with 5 ml. of buffer, followed by centrifugation at 0° for 10 min. at 10,000 r.p.m. Nucleosides and nucleotides of the highest purity commercially available were used. Thymidine and thymidylate were further purified by ion exchange and paper chromatography. Thymidylate-³²P was synthesized chemically from thymidine and ³²P-orthophosphoric acid by the procedure described by Hurwitz for cytidylic acid⁴ and purified by ion exchange and paper chromatography. 98 per cent of the radioactivity in the final product was hydrolysed by snake venom phosphatase and 99 per cent by semen phosphomonoesterase⁵. Thymidylate kinase activity was assayed by a slight modification of the method of Lehmann *et al.*⁶. In the first stage of the procedure three components were employed: 0.1 M *tris* buffer, pH 7.5 (150–195 μ l.), tissue extract (5–50 μ l.), and substrate mixture (100 μ l.) of the following composition: 40 μ moles of *tris* buffer (0.1 M, pH 7.5), 4 μ moles of magnesium chloride, 2 μ moles of adenosine triphosphate and 40 μ moles of thymidylate-³²P containing 50–200 c.p.m./ μ mole. The sequence of addition of each component was found to be important (see below), and for maximum enzyme activity the reaction was started by adding tissue extract as the last component. The reaction mixture was incubated for 15 or 30 min. at 37°, and the reaction was stopped by heating in a boiling water-bath for 2 min. In the second stage the unreacted thymidylate was hydrolysed with semen phosphomonoesterase as described⁶. Finally, the phosphomonoesterase-resistant material was adsorbed on

Fig. 2. Effect of thymidylate (TMP) and thymidine (TdR) concentration on thymidylate kinase activity during pre-incubation at 0°. Tissue extract (as in Fig. 1) was pre-incubated at 0° for 10 min. with 195 μ l. of *tris* buffer containing the indicated amounts of thymidylate or thymidine. The activity was assayed and the results expressed as in Fig. 1.

Fig. 1. Effect of pre-incubation at 0° with *tris* buffer, thymidylate (TMP), adenosine triphosphate (ATP) and thymidine (TdR) on thymidylate kinase activity. 5 μ l. (200 μ gm. protein) of an extract of 48-hr. regenerating rat liver acetone powder was pre-incubated at 0° with 195 μ l. of *tris* buffer alone ('control'), or with buffer containing 1 μ mole of thymidylate, 10 μ moles of thymidine, or 10 μ moles of adenosine triphosphate in a final volume of 200 μ l. At the intervals indicated, enzyme activity was determined by adding 100 μ l. of substrate mixture (cf. text) and incubating at 37° for 30 min. The results are expressed as percentage of maximum enzyme activity, determined by assaying the extract without pre-incubation.

charcoal, which, in turn, was collected on a membrane filter ('Ultraflex', Schleicher and Schuell Co.), washed thoroughly with cold water, dried, and counted with a micromil end-window counter. All values were corrected for a blank containing no enzyme. A unit of enzyme activity is defined as that amount of enzyme which in 1 hr. renders 100 μ moles of thymidylate resistant to phosphomonoesterase. The specific activity is expressed as units per mgm. of protein, determined by the method of Lowry *et al.*⁷.

For studies of enzyme stability a dilution test was devised. Tissue extract was diluted with *tris* buffer to a final volume of 200 μ l., and the mixture was 'pre-incubated' at 0°, usually for 10 min. Substrate mixture, 100 μ l., was then added and thymidylate kinase was assayed as described above. Compounds tested for their ability to protect the enzyme were incorporated into the buffer used for dilution.

'Pre-incubation' of tissue extract in *tris* buffer at 0° prior to incubation at 37° with the substrate mixture resulted in a rapid, irreversible decrease of enzyme activity to a minimal value of 20 per cent (curve marked 'control' in Fig. 1) of that found in the same extract assayed without pre-incubation. This observation suggested that a substance in the substrate mixture was protecting the enzyme against loss of activity. Hence, adenosine triphosphate and thymidylate were added separately to the buffer in which the tissue extract was diluted and pre-incubated. Enzyme activity was protected fully when thymidylate was present in the diluent (curve marked TMP in Fig. 1), but adenosine triphosphate had no effect. Thymidine also protected enzyme activity (Fig. 1), but for full protection 10 times as much thymidine (25 μ M) was required as compared with thymidylate (Fig. 2). The following compounds at concentrations of 2.5 μ M and 25 μ M did not protect thymidylate kinase activity in the dilution test: the monophosphates of adenosine, guanosine, cytidine and uridine, and the corresponding deoxyribonucleotides; cytidine, uridine, deoxycytidine, deoxyuridine, and thymine. Bovine serum albumin, ribonucleic acid and deoxyribonucleic acid were also without effect. The supernatant solution obtained by boiling

liver extract for 2 min. followed by centrifugation protected the enzyme in the dilution test. Boiled extract from regenerating liver exerted a greater protective effect than did that from resting liver. The protective factor in boiled extract could be adsorbed on activated charcoal and eluted with ammoniated ethanol. Although it has yet to be identified, it is presumed to be thymidylate or thymidine in view of the specificity of these compounds with respect to enzyme stabilization.

The inclusion of 10 mM thymidine in the buffer used for extracting fresh tissue or acetone powder has resulted not only in stabilization of thymidylate kinase activity in the dilution test, but also in a larger yield of enzyme activity (Table 1). This observation has proved of practical value in our present efforts to purify the enzyme. With preparations from regenerating rat liver full recovery of kinase activity is achieved following dialysis against thymidine at pH 7.5, but in the absence of thymidine activity is completely lost. This is also true for other manipulations, such as salt fractionation and gel adsorption.

Table 1. EFFECT OF THYMIDINE IN THE EXTRACTION MEDIUM ON THYMIDYLATE KINASE ACTIVITY

Preparation	Extraction medium	Thymidylate kinase activity (units/mgm. protein $\times 10^3$)	
		Control	Pre-incubated for 10 min.
48-hr. regenerating rat liver acetone powder extract (5 μ l.; 200 μ gm. protein)	Tris buffer	26.9	6.1
	10 mM thymidine in Tris buffer	32.1	30.9
Resting rat liver extract (50 μ l.; 900 μ gm. protein)	Tris buffer	1.3	0.7
	10 mM thymidine in Tris buffer	2.4	2.7
Rat thymus extract (20 μ l.; 140 μ gm. protein)	Tris buffer	74.2	15.7
	10 mM thymidine in Tris buffer	182.0	144.0
Frozen calf thymus acetone powder extract (5 μ l.; 100 μ gm. protein)	Tris buffer	84.0	22.0
	10 mM thymidine in Tris buffer	117.0	120.0

The demonstration that thymidylate kinase activity is labile under certain conditions, but is stabilized by thymidylate and by thymidine, suggests that the increase in enzyme activity in rat tissues following *in vivo* thymidine administration is at least in part attributable to protection of the enzyme by its substrate. Work now in progress with purified enzyme preparations is designed to test this hypothesis and to elucidate the mechanism of enzyme protection by thymidine and by thymidylate.

This work was aided by grants from the American Cancer Society and the U.S. Public Health Service.

PHYSIOLOGY

Specificity of the Effects of Cardiac Glycosides on the Rhythmic Contraction of Single Cultured Cardiac Muscle Cells

FROM fragments of embryonic chick hearts treated with trypsin, single, rhythmically contracting cells can be grown in a fluid, semisynthetic culture medium¹. Exposure of these cells to cardiac glycosides in concentrations as low as 10^{-9} – 10^{-8} M results in an increase in the rate of beat². In addition the pulsations appear to become stronger. At concentrations of 10^{-7} M and above, the acceleration of pulsation is soon followed, or is accompanied, by disturbances of automaticity and of co-ordinated contractile activity. By means of phase-contrast, high-speed microcinematography of cells anchored to the glass surface these effects could be studied in greater detail³. The motion pictures revealed changes at the cellular level which strikingly resembled some of the familiar manifestations of digitalis poisoning in the heart of animals and of man. Such phenomena as partial and complete block of propagation of the contraction wave (presumably due to block of conduction), bigeminal rhythm, ectopic beats, tachycardia, and fibrillation could all be observed in single isolated ventricle cells.

It seemed worth while to find out whether these effects were specific in the sense that they are elicited solely or preferentially by compounds possessing the various molecular features required for the characteristic action of the cardiac glycosides on the intact heart. By the use of compounds lacking one or the other of these features, but possessing the rest of them, it has been possible to establish a fairly high degree of structure-dependent specificity for the action of cardiac glycosides on cation movement in erythrocytes⁴ and on respiratory cardiac tissue metabolism⁵, and to rule out such specificity for certain effects exerted on contractile heart muscle proteins⁶.

Two compounds of this type, hexahydroscillaren A and allocymarin, were selected for the experiments described below. They were compared to the closely related, biologically potent natural glycosides, scillaren A and cymarin. Hexahydroscillaren A is derived from scillaren A by hydrogenation of the doubly unsaturated six-membered lactone side grouping and of the 4,5-double bond in the steroid nucleus, the C₆-hydrogen atom assuming the α -orientation (*trans* junction of rings A and B). Allocymarin (17-*isocymarin*) is formed from cymarin by inversion of the substituents at C₁₇ of the nucleus, the butenolide ring becoming α -oriented. Except for an antagonism exhibited under certain conditions against scillaren A, hexahydroscillaren A has no significant effect on the heart, while the potency of allocymarin is about 1/100 that of cymarin⁷. Solutions of the glycosides in ethanol (5 mgm./ml.) were prepared and were appropriately diluted with culture medium prior to use.

Single pulsating myoblasts were grown under sterile conditions in sealed and inverted hollow-ground slides by the method referred to above from enzymatically and mechanically dissociated ventricular cardiac muscle of 13 days old chick embryos. After 24 hr. of incubation at 37°C. the initially spherically shaped cells had flattened on, and become fastened to, the surface of the cover slip. The culture

Table 1. COMPARISON OF THE EFFECTS OF HEXAHYDROSCILLAREN A AND SCILLAREN A AND OF ALLOCYMARIN AND CYMARIN ON ISOLATED PULSATING MYOBLASTS CULTURED FROM EMBRYONIC CHICK HEART VENTRICLES

Culture No	Glycoside	Concentration		Number of cells observed	Rate of pulsation, Mean $\pm$ standard deviation	P	Irregularities of pulsation
		$\mu\text{gm./ml.}$	$\mu\text{moles/l.}$				
7	—	—	—	44	52 $\pm$ 17	~ 0.25	No
7	Hexahydroscillaren A	1.0	1.43	50	57 $\pm$ 17		No
7	—	—	—	22	55 $\pm$ 16		No
7	Scillaren A	0.1	0.14	13	34 $\pm$ 35	< 0.005	Yes
1	—	—	—	22	52 $\pm$ 21		No
1	Allocymarin	1.0	1.82	48	57 $\pm$ 20	~ 0.5	No
8	—	—	—	45	54 $\pm$ 28		No
8	Cymarin	0.1	0.18	87	72 $\pm$ 34	< 0.005	Yes

medium was then changed several times in order to ascertain that the rate of pulsation was not affected by fresh medium. A final change was made to medium containing glycoside or ethanol, the concentration of the latter corresponding to that of the alcohol in the glycoside solution (0.002 and 0.02 per cent). The cells were observed at $37 \pm 0.3^\circ \text{C.}$ with a phase-contrast microscope equipped with a warm stage.

Table 1 summarizes the results of experiments in which scillaren A and cymarin were used in final concentrations of 1.4 and $1.8 \times 10^{-7} M$, respectively, while the concentration of their structural analogues was set at 1.4 and $1.8 \times 10^{-6} M$. The results show that scillaren A and cymarin caused a significant increase in the rate of pulsation. They also caused previously quiescent cells to pulsate. In a number of cells disturbances of rhythm and contraction were observed, terminating in some instances in fibrillatory movements and stand-still. Hexahydroscillaren A and allocymarin on the other hand, though present at ten times higher concentrations than their cardio-active congeners, were without significant chronotropic action, did not induce rhythmicity in quiescent cells, and produced no irregularities of beat. Thus the structural requirements for the display of biological activity by steroid lactones are as stringent in the cultured embryonic heart cell, at least so far as the present structure-activity relationships are concerned, as they are known to be in the adult vertebrate heart.

These findings make us feel rather confident that in our previous work on the behaviour of cultured heart muscle cells in the presence of cardiac glycosides we had not been dealing with irrelevant phenomena. One is encouraged to pursue the study further of this variety of a cardiac cell for whatever new information it might yield on the cellular basis of cardiac glycoside action.

We are indebted to Prof. A. Stoll, Basle, for a gift of hexahydroscillaren A and scillaren A and to Prof. T. Reichstein, Basle, for a gift of allocymarin and cymarin.

Adrenaline and Blood Lipids

ADRENALINE has a powerful effect on carbohydrate metabolism. The effect of this hormone on nitrogen excretion has also been studied¹. However, little is known about its effect on blood lipids. In the present work, adrenaline was administered in doses of 1 mgm. to normal individuals after a 14-hr. fasting period. Blood samples were taken initially and every hour for 4 hr. after the injection. In all samples total lipids and phospholipid phosphorus were measured. For the determination of total fats the following method was used²: 0.1 ml. of plasma was applied to a filter paper and dried. The filter paper was previously washed with alcohol/ether solution 3:1. The paper with the dried plasma was soaked for 60 mm. in a sudan black solution (100 mgm. of the dye in 100 ml. of 50 per cent ethanol) and then washed three times for 15 min. with 50 per cent ethanol. The spots were cut and eluted in 6 ml. of 25 per cent acetic acid in ethanol. The colour density was determined at 590 $\mu\text{m.}$ The results are expressed in mgm. of lipids per 100 ml. A calibration curve was prepared by using a standard solution of purified olive oil (1 per cent in a hot mixture of alcohol/ether 3:1). It was noticed from preliminary experiments that by this method nearly all lipids are measured. This method is more sensitive for determination of plasma lipids than visible lipaemia, and proved satisfactory for routine work.

For determination of phospholipids the Zilversnit-Davis method was used³. The results are expressed in mgm. of phospholipid phosphorus per cent.

The effect of adrenaline on plasma lipids is presented in Table 1. Normal untreated individuals show a trend towards an increase in total lipids in plasma, due probably to mobilization of depot fats. The phospholipid phosphorus remains practically constant. Individuals treated with adrenaline showed a slight decrease in total lipids accompanied by an increase in phospholipid phosphorus.

Table 1. EFFECT OF ADRENALINE ON PLASMA LIPIDS

	Control			Adrenaline		
	T.L.	P.P.	R.	T.L.	P.P.	R.
Before	307 $\pm$ 13	9.85 $\pm$ 0.22		312 $\pm$ 11	9.75 $\pm$ 0.81	
Injection			3.17			3.12
First hour	317 $\pm$ 11	9.25 $\pm$ 0.29		300 $\pm$ 5.6	10.30 $\pm$ 0.09	
			2.98			3.43

			2.90			3.94
Third hour	332 $\pm$ 6	9.50 $\pm$ 0.19		307 $\pm$ 8.2	12.70 $\pm$ 0.18*	
			2.90			4.09
Fourth hour	340 $\pm$ 7	10.00 $\pm$ 0.20		305 $\pm$ 9	10.40 $\pm$ 0.25	
			2.94			3.49

T.L., Total lipids (mgm. per cent); P.P., phospholipid phosphorus (mgm. per cent); R, ratio P.P./T.L. The values represent the average of 18 individuals, after a 14-hr. fasting period. Adrenaline was given, 1 mgm. subcutaneously.

* $P < 0.02$.

The effect of adrenaline on plasma is better illustrated by calculating the ratio phospholipid phosphorus/total lipid. There is a definite increase in this ratio after administration of adrenaline, which is evident after the first post-injection hour and lasts 1-3 hr.

That adrenaline may have an effect on lipid metabolism is suggested by the observation that large doses of adrenaline (1 mgm. per kgm. body-weight) in rabbits produce a calorogenic effect, 2-3 hr. after injection, along with a decrease in plasma fatty acids⁴. However, this experiment gives no information on phospholipid phosphorus, and the doses used do not approach any physiological or therapeutic dose. From our experiment the conclusion is drawn that adrenaline increases the percentage of phospholipid component of serum lipids.

Catalase Activity of Mouse Liver and its Relation to the Condition of the Animal

In papers dealing with methods of determining catalase activity in animal tissue, while dealing with the experimental conditions, usually little attention is paid to the condition of the animal. We have found the latter to be of utmost importance.

The two methods mostly employed in the determination of catalase activity in animal tissue, the titrimetric and gasometric method, have been compared by Greenstein¹ and by Dounce and Shanewise². The former found different values; the latter workers obtained the same values in both methods. Chance³ made a thorough spectrophotometric investigation of the decomposition of hydrogen peroxide by catalase.

In our experiments we used the apparatus described by Appleman⁴. The animal was killed by decapitation, the liver removed, weighed and homogenized with 3 ml. water in a Griffith tube. After centrifugation the supernatant was diluted with 0.1 N Sorensen phosphate buffer of pH 7.0. 3 ml. of this solution—equivalent to about 0.9 mgm. of tissue—were mixed in the Appleman apparatus with 5 ml. of 3 per cent hydrogen peroxide buffered with 0.1 N Sorensen phosphate buffer solution at 29° C. The unit of catalase activity (activity factor) is expressed as ml. oxygen per gram tissue (dotted lines in Fig. 1) or per whole liver (solid lines in Fig. 1) per second. The reproducibility was better than 5 per cent.

We used male homozygotic Swiss mice in order to exclude possible differences in liver catalase activity of the two sexes as reported by Adams⁵.

We expected a normal distribution curve (symmetrically, positively or negatively J-shaped) of the activity factors of normal mice. Curve I was obtained (dotted lines, activity factors per gram; solid lines, per whole liver).

Fig. 1

Fasting the mice for 24 hr. before the analysis gave a slightly better picture (curve II).

We then reasoned that 'placing the animal in a 'steady state' probably would give better results. We imagined the liver to be composed of machinery (enzyme systems) and products (glycogen, proteins). When all mice receive the same food (quality and quantity) and have to produce the same amount of energy every day, one would expect that the liver would be in a 'steady state', and therefore the enzyme apparatus in all the mice livers would be practically the same. For the determination of liver catalase in this way we used mice 38-57 days old, which we raised in a stable at 24° C. They were exposed to artificial light from 8.30 until 17.00 hr. Every mouse of the same age received the same quantity and quality of food. Water was given *ad libitum*. The results are reproduced in curve III.

During cold nights the stable did not reach 24° C., so finally we set up an experiment using constant temperatures in the stable. Only normal growing mice—controlled by weighing—were used. All organs of the mice used were checked macroscopically for abnormalities; if any were found, the respective

activity factor was excluded. All mice were adult (about 90 days old). The result is shown in curve IV.

The spread in liver catalase activity factors per whole liver was thus reduced from 4-54 (curve I) to 8-22 (curve IV) or to 28 per cent of the original value.

With this method we tested substances separated from cancer tissue. When injected in mice the substances produce a marked decrease in liver catalase activity. Our results agree with those of Nakahara and Fukuoka with 'toxohormone'.

Toxicity of a Single Subcutaneous Dose of Sodium Selenite in Pigs

SINCE the activity of 'factor 3' in liver necrosis in rats and exudative diathesis in chicks was shown to be dependent on selenium¹, compounds of this element have been shown to prevent other diseases induced by tocopherol-deficient diets. Sodium selenite (0.2 p.p.m.) as well as tocopherol acetate inhibit muscular degeneration in pigs fed grain, which causes field outbreaks². Muscular degeneration in pigs is associated with a rise in plasma glutamic-oxaloacetic transaminase, but normal ornithine-carbamyl transferase³. When the disease is manifested, high glutamic-oxaloacetic transaminase levels rapidly return to normal after subcutaneous administration of 0.02 mgm. selenium (as Na₂SeO₃) per kgm. body-weight daily for three days (Orstadius *et al.*, unpublished work).

In veterinary medicine selenium has long since been known as a cause of poisoning in farm animals ('blind staggers', 'alkali disease'). 6-8 mgm. selenium per pound of body-weight as a single oral dose of sodium selenite is the minimum lethal dose for pigs⁴. Intoxicated animals showed emesis, diarrhoea, apathy, unwillingness to move, shivering and sometimes paresis before death. No thorough examination of the muscles was done.

Sodium selenite was given subcutaneously to pigs weighing 30-70 kgm. 2.0 mgm. and 1.2 mgm. selenium per kgm. body-weight caused death after 4 hr. and five days, respectively, during which time the pigs showed trembling, ataxia and paresis. Plasma glutamic-oxaloacetic transaminase was significantly increased (Fig. 1); but plasma ornithine-carbamyl transferase was normal, indicating that muscle but not the liver was affected⁵. At post-mortem examination the body musculature showed extensive dystrophy; but other organs, including the liver, showed no significant changes.

0.9-1.1 mgm. selenium per kgm. body-weight caused slight to moderate elevation of plasma glutamic-oxaloacetic transaminase in about half the

Fig. 1. x, 0.0; o, 1.0; ●, 1.1; Δ, 1.2; ▲, 2.0 mgm./kgm. body-weight

number of pigs so treated, but otherwise no symptoms of disease. The ornithine-carbamyl transferase values were normal. The elevations of glutamic-oxaloacetic transaminase returned to the starting-level after a day or two. Biopsy specimens from the longissimus dorsi showed no changes at microscopical examination.

0.8 mgm. selenium per kgm. body-weight or smaller doses gave no increase of transaminase.

It is remarkable that the anti-muscular degeneration effect of low selenium doses corresponds to a high vulnerability of the muscles to increased selenium doses.

Effects of γ-Aminobutyric Acid and Picrotoxin on Spontaneous Activity in the Central Nervous System of the Crayfish

SINCE the extraction of an inhibitory substance (factor I) from mammalian brain¹, one constituent of which was identified as γ-aminobutyric acid², this constituent has been tried on a number of invertebrate preparations³. It imitates the action of inhibitory neurones in crayfish and on injection into the animal results in flaccidity⁴. The action of γ-aminobutyric acid is very similar to that obtained on stimulation of the inhibitory fibres in crayfish stretch receptors⁵. The effects of γ-aminobutyric acid are counteracted by picrotoxin in this preparation³ as well as in crayfish hearts⁶. Picrotoxin

Fig. 1. Records of integrated electrical activity in 8- γ -aminobutyric acid-picrotoxin antagonism experiments. Records should be read from right to left. Full scale is 20,000 impulses per min.; vertical lines delineate 1 min. periods of recording; arrows indicate periods of rinsing in van Harreveld's solution; 'IMMED' shows activity recorded immediately after isolation of the ganglion. A, pH 7.5; B, pH 6.6; C, picrotoxin pH 7.5, γ -aminobutyric acid pH 6.6.

by itself is a convulsant in crayfish⁸, although no effect on synaptic transmission is observed using 2.5×10^{-4} M picrotoxin⁸. However, concentrations greater than 10^{-6} M progressively decrease the effect of inhibitory nerve stimulation in crayfish claws⁸.

Although only peripheral inhibition has been demonstrated in the crayfish, it is not unreasonable to expect that inhibitory pathways may be present in the central nervous system. If this is so, it might be possible to demonstrate them if the transmission process is blocked by picrotoxin and depends on γ -aminobutyric acid.

The preparation used was the fifth abdominal ganglion of the crayfish, *Orconectes virilis*. The ganglion was held between electrodes and the electrical activity counted by electronic scalars, integrated and then fed into a graphic ammeter. (The details of the technique used are in the thesis, "Spontaneous Electrical Activity in the Crayfish Central Nervous System", by J. K. Hichar, Harvard University, 1958, *J. Cell. Comp. Physiol.*, 55, 195; 1960). Control levels of activity were obtained by recording the activity from the ganglion in a layer of oil after it had been immersed in a van Harreveld's solution¹⁰ for a period of at least 15 min. After the control level was established the ganglion was then immersed in a test solution for 1 min. and the activity recorded again after raising into the oil layer. For each level of activity obtained after contact with a drug, the preceding activity was used as the control. Normally, when the effects of a particular drug were being tested, the progression of concentrations was from weak to strong concentrations. All drug solutions were made up in van Harreveld's solution and the experiments were conducted at room temperature, which varied from 24° to 26° C.

In 4 out of 5 experiments γ -aminobutyric acid, in concentrations of 10^{-10} to 10^{-2} M, had no effect on spontaneous activity of the fifth ganglion; β -alanine was found to have effects similar to those of γ -aminobutyric acid on the crayfish stretch receptor but to be 1/20 as active³. On the ganglion β -alanine caused a gradual enhancement of the activity, commencing at 10^{-4} M and inhibition occurring at 10^{-2} M.

The effects of picrotoxin were more striking. As the concentration increased from 10^{-8} M there was a

gradual increase in activity until 10^{-4} M was reached, when the activity was maximal. After exposure to 10^{-4} M picrotoxin for approximately 3 min. depression occurred. This was more obvious when yet higher concentrations were used. It was common for units to fire repetitively when treated with picrotoxin. These bursts began long before increases in overall level of activity were apparent; in most cases before a concentration of 10^{-7} M was reached. These effects were irreversible after periods of washing as long as 30 min.

Several experiments were then conducted in order to determine whether pre-treatment with picrotoxin and the resulting excitation could be influenced by subsequent treatment with γ -aminobutyric acid. The results of one such experiment

appear in Fig. 1A. In this experiment after the usual picrotoxin excitation subsequent treatment with 10^{-4} or 10^{-2} M concentrations of γ -aminobutyric acid failed to influence this high level of activity.

To determine if a lower pH would change the activity in any way, as was suggested by Florey¹, a nerve cord was soaked in 10^{-2} M picrotoxin for 30 min. at a pH of 6.6. The activity was recorded for 5 min., after which the preparation was immersed in 10^{-4} M γ -aminobutyric acid of the same pH for 2 min. The electrical activity was again recorded for 5 min. and the results appear in Fig. 1B. Here it can be seen that the increase which began after the treatment with picrotoxin continued at close to the same rate after immersion in γ -aminobutyric acid.

Other experiments were conducted where nerve cords were soaked for 30 min. in 10^{-2} M picrotoxin at pH 7.5. Activity was recorded for 5 min. which was followed by immersion in 10^{-4} M γ -aminobutyric acid at pH 6.6 for 2 min. and recording again done. Results of this experiment appear in Fig. 1C. Here it can be seen that the initial increase in activity after soaking for 30 min. in the picrotoxin solution was in no way influenced by the considerably higher concentration of γ -aminobutyric acid, and the level remained constant.

The suggestion was made that acetylcholine and factor I are the transmitters of opposite action in crayfish^{8,11}. Since no evidence was obtained for a neurohumoral function of γ -aminobutyric acid in the preparations used here, it appears that the situation may not be so simple. It may be that γ -aminobutyric acid is a precursor of factor I¹². On the other hand, there is no *a priori* reason to assume that in an inhibitory pathway (or in any pathway for that matter) the same transmitter must be used at all synaptic junctions. It is entirely possible as in the vertebrate autonomic system that different transmitters are involved. Thus γ -aminobutyric acid might be the inhibitory transmitter at the periphery, and not be utilized in the central nervous system. However, a few experiments done on an intact animal where γ -aminobutyric acid was injected into a walking leg and proprioceptive responses were elicited from a sensory neurone, did not give evidence of any effect of the substance, although it was found to block the lobster seventh median thoracic stretch

receptor, which has no inhibitory synapse¹³. This would suggest that γ -aminobutyric acid or a substance similar to it is not a general peripheral inhibitory transmitter.

The different effects of β -alanine at central synapses found here and peripheral ones³ suggest a central inhibitory transmitter that differs from that at the periphery. The different effects of picrotoxin observed in these two areas also support this hypothesis. The results presented here show picrotoxin to be highly irreversible in the crayfish central nervous system, whereas it appears to be easily reversible at the periphery^{7,9}. Picrotoxin in low concentrations does not alter the spontaneous activity of the stretch receptor neurone, but it antagonizes the inhibitory effect of factor I⁷. Van der Kloot *et al.*⁸ reported that picrotoxin blocks the effect of stimulation of the inhibitory nerve in crayfish chela muscle. Elliott and Florey⁷ also reported that picrotoxin had convulsive effects in crayfish and it was found to excite the ganglia. Thus the effect of picrotoxin differs peripherally and centrally. These observations indicate that the drug may have a different action at central synapses from that at peripheral ones where the transmitters involved may differ. That is, picrotoxin may, as van der Kloot *et al.*⁸ suggest, block the action of the inhibitory transmitter peripherally in a curare-like manner by joining the receptor molecule. Its central action, however, may be quite different.

This work was supported in part by research fellowship BF-7367 from the National Institute of Neurological Diseases and Blindness, Public Health Service. I am indebted to Prof. John H. Welsh for generous help and encouragement.

Incorporation of Amino-Acids labelled with Carbon-14 in Nerve Proteins during Activity and Recovery

THAT nerve proteins may take an active role during nerve impulse propagation has been proposed in many publications¹. In a paper, now in the press, I have suggested that a small fraction of the nerve proteins may split, probably to the level of amino-acids, during nerve activity, and that this process should be fully reversible, appearing as an increased turnover of proteins during impulse conduction or shortly afterwards. The purpose of the present

communication is to present evidence in support of these suggestions.

In each experiment, 4-6 desheathed sciatic nerves (800-1,600 mgm. of nerve) from the South American frog *Callyptocephalus gally* were immersed for 1 hr. in 10 c.c. of Ringer solution containing 20-40 μ c. of a mixture of amino-acids labelled with carbon-14 (hydrolysate of *Chlorella* protein). Then half the nerves were placed on electrodes and stimulated for 30 min. with square pulses of 0.2 msec. duration at 1-2 V. at a frequency of 120/sec. To control conduction and the maximal response, the activity of the nerves was continuously displayed on an oscilloscope. The other half of the nerves were also placed on electrodes for the same length of time, but were not stimulated. At the end of the 30 min. period, both groups were washed twice, for 15 min. each time, in Ringer solution without amino-acids. After washing, the nerves were frozen and crushed with ground glass in a mortar, and their proteins extracted in 0.1 M potassium chloride (15 c.c. of extract). The extracts were clarified in a refrigerated centrifuge at 20,000g for 1 hr. and the supernatant of each sample was treated with the same volume of 20 per cent trichloroacetic acid and left overnight. Next day, the precipitates were filtered and washed with 5 per cent trichloroacetic acid and with alcohol-ether (three times each). The precipitates were retained in filter papers, which were then transferred to aluminium planchets and the radioactivity of the precipitated protein was measured with a gas-flow counter (Nuclear Chicago Model D 47 with micromil window). Afterwards, the nitrogen content of each filter paper and precipitate was determined by micro-Kjeldahl analysis. The nitrogen content of the protein was obtained by subtracting the average nitrogen content of the filter paper.

Amino-acid incorporation of the experimental (stimulated) and control (not stimulated) samples was compared from their specific activities expressed in terms of counts/min./mgm. of nitrogen. Table 1 shows the results of seven experiments. It can be seen that the proteins from the stimulated nerves incorporated more activity than those of the controls. The average increase in activity due to stimulation was 48 per cent with a high standard deviation of 23.

Exp. No.	1	2	3	4	5	6	7
$E \left(\frac{\text{counts/min.}}{\text{mgm. N}} \right)$	186	151	118	135	175	185	139

E = standardized specific activity of the experimental group, taking the value for the control group as 100.

These results can probably be interpreted as due to an increase in protein turnover during nerve impulse propagation or shortly afterwards. Similar observations have been made with respect to the protein turnover in the central nervous system after intense stimulation² (although in this latter case glucose labelled with carbon-14 was used as the source of markers). However, as the results presented here were obtained on isolated peripheral nerves, they support more directly the idea that nerve proteins have a more active role in impulse propagation and recovery than those obtained using the central nervous system, where other processes may be involved. Furthermore, these findings suggest a way of labelling the proteins that participate actively in nerve function (impulse propagation) and make possible their isolation and study.

I am indebted to Miss Ines Hoppe and Miss Silvia Rissetti for technical assistance, as well as to Miss

Emmy Wittig, who kindly carried out the nitrogen analyses. The experiments were made with equipment purchased by the Rockefeller Foundation, to which we are much in debt. I thank also Dr. Hodgson, who provided the mixture of labelled amino-acids.

Hydroxyproline and the Shrinkage Temperature of Collagen

Dr. B. J. Rigby and Dr. J. D. Spikes¹ have quoted a value of 8.3 per cent for the hydroxyproline content of fibrinoid tissue as being taken from a paper by Bowes, Elliott and Moss². The figure given in this paper is in fact 7.6 for the hydroxyproline-nitrogen expressed as per cent of the total nitrogen of the gelatin solution obtained on autoclaving fibrinoid tissue. Assuming a total nitrogen content of 18 per cent, this corresponds to 12.8 per cent hydroxyproline on protein weight which, according to Fig. 1 of Rigby and Spikes, should give a T_g of 60° or more. Their suggestion that rheumatic effects are the result of a structural breakdown due to temperature effects only is, therefore, not supported.

We would also like to direct the attention of the authors to certain exceptions to the argument that the T_g of collagen is related to its hydroxyproline content, for example, invertebrate collagens³⁻⁵.

In the absence of any evidence that the preparation is homogeneous it seems more likely that variation in the hydroxyproline content of mammalian tissues is an indication of the collagen content, rather than of differences in the composition of the collagen itself.

⁵ Watson, M. R., and Silvester, N. R., *Biochem. J.*, **71**, 578 (1959).

We regret the error in our original publication¹, and thank Drs. Bowes and Moss for the correction. As they point out, the T_g corresponding to the correct value for the hydroxyproline in the example quoted is about 60° C. However, as was stated in the original article of Bowes, Elliott and Moss², fibrinoid tissue from patients suffering from rheumatic fever and rheumatoid arthritis contains less hydroxyproline than normal tissue, so that our statement was qualitatively correct. We reiterate our main theme, that since the denaturation and shrinkage of collagen is a time-dependent process³, collagen will denature at temperatures below the instantaneous shrinkage temperature given a sufficiently long time, and that this time will be reduced (at any fixed temperature) if the percentage of hydroxyproline is also reduced. Gustavson⁴ has presented experimental evidence along these lines showing that calf-skin begins to denature in water at 45° C. after one week. Stress

relaxation studies⁵ also show that rat-tail tendon slightly extended in 0.9 per cent saline begins to denature at about 40° C., although there is no tendency for the tendon to shrink when unloaded. We consider this to be the beginning of the structural breakdown which, however, only takes place on a large enough scale to cause instantaneous shrinkage at the higher temperature known as the shrinkage temperature.

With reference to invertebrate collagens we point out that our speculations applied only to vertebrates and were applicable only because of the similar chemical nature of these collagens. With invertebrate collagen the greater variability in chemical composition⁶ means that differences in chemical properties cannot be related to one particular constituent.

HÆMATOLOGY

Possible Origins of the Anti-Gm Sera

SINCE Grubb and Laurell discovered the Gm factor in 1956 (ref. 1), all those who have worked in this field have carried out the tests with sera from patients suffering from rheumatoid-arthritis diseases. Thus Harboe and Lundevall² and then Harboe³ found and described the Gmx and Gmb factors in 1959. Also using a rheumatoid-arthritis serum, Steinberg⁴ was able to demonstrate in the sera of Negroes the presence of a Gm-like factor, a factor which is not found in the white population. In 1959, however, Grubb found an anti-Gm factor in the serum of a young girl who was suffering from hepatitis with plasma cells⁵.

Investigation of the Gm factor is based on the fact that a certain percentage of normal sera has the property of inhibiting the agglutinating power of some rheumatoid-arthritis sera. It is characteristic of this agglutinating power that the sera agglutinate O CDE red cells sensitized by an incomplete anti-D. Such agglutinating powers have been found and described by Milgrom *et al.* in the sera of clinical patients and by Unger *et al.* in the sera of healthy persons. But these authors have also noticed the non-inhibition of these agglutinating powers by the adjunction of human γ -globulins or normal sera.

From examination of more than 12,000 blood donors from the population of the Seine-Maritime, France^{6,7}, and also patients from different departments of our hospital, we have found this agglutinating power in some sera. But these sera could be inhibited by the adjunction of other normal sera⁸. Further investigations have shown that these sera were anti-Gm.

Hence, at the present time, we have been able to demonstrate the presence of anti-Gma in the sera of

Table 1

		Dilutions of the normal sera									
		1:2	1:4	1:8	1:16	1:32	1:64	1:128	1:256	1:512	1:1,024
Blood donor's sera	Gm + serum	—	—	—	—	—	—	—	—	—	—
	Gm — serum	++	++	+++	+++	+++	++++	+++	+++	+++	—
Rheumatoid-arthritis sera	Gm +	—	—	—	—	+	++	+++	+++	+++	—
	Gm —	—	±	+	++	+++	++	+++	+++	+++	—

9 apparently healthy blood donors, and one patient suffering from pulmonary tuberculosis. The Gmx has been found in one blood donor and in the serum of one patient treated for allergic reactions. Each time, the specificities of these anti-Gm sera were checked by testing on a panel of 50 normal sera which have been tested with anti-Gma and anti-Gmx rheumatoid-arthritis sera and furthermore by genetic control of matings involving about 100 children.

From the serological point of view, it is important to direct attention on the difference which seems to exist between the inhibitory tests^{7,8}; with the rheumatoid-arthritis sera, the inhibition appears to be a quantitative phenomenon. Suitable dilutions of sera are necessary for the test, in order to demonstrate the presence or absence of the inhibitory factor. For that reason, Harboe¹⁰ has set up his method of scores.

On the other hand, when anti-Gm sera from patients (tuberculosis, allergic diseases) or blood donors are used, inhibition appears as a qualitative phenomenon. It occurs with sera Gm +, employed undiluted as well as diluted to 1/128 or more (see Table 1).

It would be interesting to study these different agglutinating properties as regards their physico-chemical aspects and particularly to investigate whether or not the anti-Gm property of rheumatoid-arthritis sera is different from that found in patients suffering from other diseases or in healthy persons.

At present, contrary to the general opinion, we find that anti-Gm sera can be present in the rheumatoid diseases, in chronic and evolutionary diseases and in healthy persons.

Note added in proof. Since this communication was submitted for publication, a new serum group has been found and called InV. The agglutinating power has been found in the serum of a healthy blood donor. This InV factor is independent of the Gma, Gmb and Gmx factors. It is present in the sera of Whites as well as Negroes. Also we have found an anti-Gmb in the sera of two other healthy blood donors.

Thalassaemia in a Tibetan discovered during a Hæmoglobin Survey among the Sherpas

As a part of an investigation into the health of the Sherpas, undertaken during the course of the British Sola Khumba Expedition during the spring of 1959, venous blood samples were obtained from 129 inhabitants of Khumbu villages, out of an estimated population of 2,500 (von Fürer-Haimendorf, C., personal communication).

The blood samples were collected into sterile vacuum tubes ('Venules', Winthrop Laboratories, Ltd.), which were then sealed with adhesive wax ('Okeria Wax 1350/2', Astor Boisselier and Lawrence, Ltd.). The sealed tubes were stored on ice in large wide-mouthed vacuum flasks for protection from cold at high altitude and from heat during the return march to Katmandu in June. The flasks themselves, supplied by the British Vacuum Flask Co., were housed in stout wooden containers with hinged lids and packed with sawdust. These were wrapped in polythene foam sheeting which could be doused with water at frequent intervals during the hot stages of the march. By these means small pieces of ice were still preserved on arrival back at Katmandu on the eighth day after the last opportunity to recharge the flasks. The samples were flown back to London in ice-filled flasks, when they were taken at once to St. Bartholomew's Hospital.

All the samples were examined for hæmoglobin F by the 1' alkali denaturation test¹. In view of the presence of hæmoglobin H in Chinese and South-East Asian populations in general, and of the finding of hæmoglobin E in Malaysians and occasionally in Ghurkas, all samples were tested by electrophoresis at alkaline pH using barbiturate buffer². They were further examined by electrophoresis in *tris* buffer³ to determine the level of hæmoglobin A₂. No abnormalities were discovered in 128 blood samples, but in one, 5.9 per cent alkali-resistant hæmoglobin was found, and the hæmoglobin A₂-level was seen to be raised above the normal 3.5 per cent (Fig. 1). The finding of a significant amount of hæmoglobin F, and of a raised hæmoglobin A₂-level is diagnostic of thalassaemia minor. The only other evidence of a thalassaemia gene in a Himalayan population was made in the Ghurkas⁴, who, however, are racially quite distinct from the Sherpas.

The Sherpas live on the southern watershed of the main Himalayan range in north-eastern Nepal in villages lying mostly at altitudes between 10,000 and 12,000 ft. They are of pure Tibetan ancestry. The man in whom the evidence of thalassaemia was discovered was a servant in the Buddhist monastery at Thyangboche, aged about seventy years, and he was born in Tibet. He was suffering from right-sided heart failure with generalized cedema, which was thought to be due to 'chronic mountain sickness' or so-called Monge's disease. The blood pressure was

Fig. 1. Hanging paperstrip electrophoresis of haemoglobin of Tibetan with 5.6 per cent F and 4.1 per cent A₂. Tris buffer, pH 8.9, stained with 'light-green'

135/95, and the serum cholesterol 119 mgm. per cent.

HISTOLOGY

Neurokeratin Network of Myelin Sheaths

THE recent communication of Tewari and Bourne¹ on the neurokeratin network of peripheral nerve fibres is valuable not only for its intrinsic content but also because it validates the histological procedures, findings and arguments derived therefrom, by which it was concluded that neurokeratin formations are part of the architecture of the nerve fibres and not artefacts^{2,3}. It is sad to think that Nageotte⁴, who saw the structures in peripheral nerve fibres described by me^{2,3} and by Tewari and Bourne, looked on them as artefacts. One of the strongest anatomical arguments against the notion of artefact is that the disposition of neurokeratin in spinal cord axons and in the preterminal axons found in spinal cord, in brain stem and in cerebral and cerebellar cortices is quite different from that characteristic of peripheral nerve trunks, even although the material examined was fixed and prepared for sectioning under strictly comparable conditions in all instances.

Work in progress shows that not only the disposition, but also the amount, of neurokeratin varies

in different parts of the nervous system. This can be shown optically by using the falgic acid staining process described elsewhere⁵. In this process sections are stained first with acidified acid fuchsin and then with a very dilute solution of light green. Acid fuchsin can combine with one, two or three molecules of light green to form red, violet or blue compounds, respectively; these have been named the falgic acids. The red compound is formed where acid fuchsin is most abundant, the blue where it is least so. Thus the relative uptake of acid fuchsin (relative erythrophilia) of tissue elements can be determined by colour. Neurokeratin is erythrophilic and the falgic acid method shows that it is present in great density in spinal cord axons, somewhat less so in peripheral and least in the axons of the white matter of the cerebral and cerebellar cortices, and indeed in fine medullated fibres everywhere. These latter fibres are therefore difficult to display by the falgic acid technique.

Nevertheless, the essential feature of this technique can be used to make such fine fibres clearly visible as well as showing the markedly erythrophilic types of axon. The falgic acids are formed by the union of one or more molecules of light green with the amino-groups of acid fuchsin, one molecule of light green uniting with one of these amino-groups. The acid fuchsin, already attached to basic elements of the tissue by its sulphonic groups, behaves as a 'trivalent' base towards the acid light green. Other acid dyes can replace light green in this type of combination. In particular, violamine 3B can be used; the red, violet and blue colours produced by the falgic acid technique are then replaced by red, purple and deep violet, respectively. If sun yellow G be mixed with the violamine solution, the erythrophilic tissue elements are stained yellow, giving a very good contrast with the elements coloured by the 'faviolic acids', as we may call them. This shows the finest nerve fibres and is a very simple technique for the display of both dendrosomatic and axonic parts of neurones. It gives a picture equivalent in detail shown to that provided by MacConaill's acid fuchsin-lead haematoxylin method², but it is free from the risk of the formation of precipitates which that method entailed. By it the staining properties of neurokeratin can be used for a demonstration of the presence of medullated fibres, and for an assessment of the relative amounts of neurokeratin present in different fibres.

Details will be published elsewhere when the work has been completed. Meanwhile it would seem that the descriptions of the structure of myelinated fibres should be drastically revised in current textbooks, notwithstanding the apparent discrepancy between the findings of optical and electrical microscopy.

Structure of the Walls of the Bile 'Canaliculi' in Mammalian Liver Cells

THE structure of the walls of the bile canaliculi of the liver has long been of interest; the question of importance being whether the canaliculi had definite walls of their own, or whether they were formed from modifications of the walls of the hepatocytes themselves. Early workers¹⁻³ believed that the canaliculi had definite walls of their own; but Zimmermann⁴ suggested that they were formed by modifications of the walls of the hepatocytes, and described dense structures at the edges of the canaliculi which he called "terminal bars". Morton⁵ was able to show that the lining of the bile canaliculi was in the form of a 'brush border', and apart from Zimmermann's terminal bars he found a collection of basophilic material in the cell cytoplasm lying close to the bile ducts. Rouiller⁶, in an electron microscope study of the rat liver bile canaliculi, showed that the cell membranes were closely opposed in the neighbourhood of the canaliculus, but with only osmium as an electron stain, he found no modification or thickenings of the cell wall in the proximity of the duct. In a study of normal and regenerating rat liver using 'Araldite' embedding followed by phosphotungstic acid staining, it was found that some parts of the cell walls related to the bile ducts took up this stain particularly well.

In liver cells stained with phosphotungstic acid, dense bands of materials are seen at various points on the plasma membrane. These bands are always exactly opposite a similar band of identical length on the membrane of an adjoining cell (Figs. 1 and 2). They cause a thickening of the plasma membrane from its usual 80-90 Å. to 500-600 Å., and are always present close to the points where the plasma membranes of two cells divide to form a bile canaliculus, although they are also to be found at other points on the cell membrane.

These structures, revealed by phosphotungstic acid staining in close relationship to the bile canaliculi of liver cells, seem in agreement with the previous work using the light microscope. Thus the dense phosphotungstic acid-positive bands on the cell membranes close to the bile canaliculi are in the same position as the "terminal bars" of Zimmermann, and are probably identical with these structures. Zimmermann's original term "Kittleisten" suggested a cementing substance, and it is therefore perhaps

not surprising to find areas of phosphotungstic acid-positive material, scattered all along the cell membrane.

Similar material has been found on the plasma membranes of mouse pituitary cells by Barnes⁷. In this case the material is neatly laminated instead of being a single band on each membrane; but the same conclusion is reached, namely, that the function

Fig. 1. Part of an elongated bile canaliculus formed at the junction of the three liver cells. The cell membranes close to the canaliculus are much thicker than normal, being as much as 500 Å. thick, and stain very densely with phosphotungstic acid. ($\times$ c. 40,000)

Fig. 2. A high-resolution picture of the cell membranes of two liver cells close to a bile canaliculus. The dense phosphotungstic acid-positive material is clearly visible. ($\times$ c. 128,500)

of this material may be to assist in the binding of cells together. The material for this work was obtained from normal adult Wistar rats. It was fixed by the method described by Barnes and Davis⁸ and embedded in 'Araldite' as described by me⁹.

PATHOLOGY

Porphyrin Fluorescence of Experimentally produced Squamous Cell Carcinoma

ULCERATED squamous cell carcinomas of the human skin frequently show a red fluorescence when examined under ultra-violet radiation¹⁻³. This red fluorescence is usually restricted to small areas of the necrotic surface. Hitherto the substance or substances responsible for this phenomena have not been identified. This is probably due to the fact that very small amounts of material are available for study in any single case. Recently, Ghadially⁴ observed that experimentally produced squamous cell carcinomas of the skin of many animals show a similar red fluorescence. It seemed to us that by pooling material from a number of tumours, sufficient might be obtained for a chemical analysis. Six rabbits with large ulcerated carcinomas produced by repeated painting of the skin with a 2 per cent solution w/w of 9:10 dimethyl 1:2 benzantracene in a mixture of equal parts of lanolin and paraffin were available for study. After many attempts, we were ultimately able to collect one large (5 gm.) pooled sample for analysis. Another large sample was obtained from a single rabbit which died as a result of a very large fungating carcinoma of the ear. Here about 5 gm. of red fluorescent debris had collected on the carcinoma and within the ear over a prolonged period of time. The results obtained in each case were essentially similar.

Red fluorescence has been attributed to the presence of porphyrins in a chloroma⁵, a fungating adenocarcinoma of the breast⁶ and a hepatic adenoma⁶ of man. Therefore it seemed reasonable to suppose that similar material might be associated with the red fluorescent squamous carcinomas.

An ethyl acetate (75 ml.)-acetic acid (25 ml.) extract of red fluorescent debris (5 gm.) from the rabbit carcinoma was examined for protoporphyrin, coproporphyrin, and uroporphyrin by the methods of Schwartz and Wikoff⁷ and Dresel and Falk⁸. The absorption spectrum of a fraction corresponding to protoporphyrin was measured in ethyl acetate solution with a Unicam spectrophotometer SP 500 in the range 350-800 mμ (in 5-mμ steps) in 1-cm. cells versus an ethyl acetate blank. Table 1 gives wave-lengths and optical density values of the maxima and minima exhibited by this porphyrin solution, and, for comparison, the corresponding values are quoted for the

spectrum of an authentic sample of protoporphyrin (Light and Co.) in ethyl acetate. These spectra were closely similar, and it may be concluded that protoporphyrin occurs in the carcinoma debris.

The fraction which should contain coproporphyrin fluoresced red in ultra-violet light, but the porphyrin content was so low that only a very feeble Soret band was detected at 400 mμ in the most concentrated extract we could obtain.

Finally, the fraction which should contain uroporphyrin according to Dresel and Falk failed to fluoresce in ultra-violet light.

Thus the material responsible for the fluorescence of rabbit ear carcinoma seems to consist mainly of protoporphyrin with perhaps a trace of coproporphyrin.

Phenylketonuria in Infant Monkeys

We had previously established¹ that the characteristic aberrations found in human phenylketonuria, namely, high plasma phenylalanine, phenylketones in the urine, and characteristic odour were observed in adolescent monkeys fed excessive amounts of L-phenylalanine in their diet. From the results of behavioural tests utilizing discrimination and maze performance, as well as poor adaptability to the test situation, these monkeys appeared to be retarded in their learning ability. It seemed important to determine whether phenylketonuria could be produced in infant monkeys when the brain is apparently more sensitive to chemical insult. Long-term observation could then be made throughout the period of development and it might be possible to correlate the biochemical changes with behavioural patterns.

Four infant macaques born in this laboratory were separated from their mothers at birth and were given a high phenylalanine milk diet from the second day of life. Whole cow's milk or powdered milk formula containing 0.25 gm. L-phenylalanine per 100 ml. in final dilution was fed for the first two weeks. Later,

increasing quantities of the amino-acid were included to a maximum of 0.5 gm. of L-phenylalanine per 100 ml. The average infant monkey consumed enough milk to make the daily intake approximately 2.75 gm. of phenylalanine per kgm. body-weight. The infant monkeys were bottle-fed by hand every 2 hr. for the first 2 weeks, then fed by means of an infant feeding bottle placed in a mother surrogate so that the infant could crawl on to this false mother for the nipple feedings in the usual position. Plasma phenylalanine was determined^{2,3} at weekly intervals for the first six months, then at bi-weekly intervals up to the first year. The urine was tested daily during the first year and revealed strongly positive phenylketones as determined by the 'Phenistix' (Ames Co., Elkhart, Indiana) or ferric chloride methods, and it had the peculiar musty odour typical of that of children with this disease. Quantitative blood and urine analyses are shown in Table 1. The fasting plasma phenylalanine of normal infant monkeys ranged from 1.0 to 1.5 mgm. per cent, while the monkeys which received L-phenylalanine ranged from 8.8 to 47.5 mgm. per cent. These high plasma phenylalanine-levels are comparable to that of phenylketonuric patients. The urine collected from male monkeys indicated that normal animals excreted negligible amounts of phenylpyruvic acid as determined by the method of Berry and Woolf⁴, while the monkeys which received L-phenylalanine excreted 79-465 mgm. phenylpyruvic acid in 24 hr.

Table 1

Monkey	Mgm. phenylalanine/ 100 ml. plasma	Mgm. phenylpyruvic acid/24 hr. urine
A 8 ♂	16.6-39.0	113-257
A 18 ♂	9.8-32.9	79-465
A 23 ♀	10.9-46.1	—
A 24 ♀	10.4-47.5	—
Controls	1.0-1.5	0

The monkeys receiving the high phenylalanine milk grew nearly as well as monkeys fed a normal laboratory diet. Those animals which consumed very high amounts of phenylalanine because they were better milk drinkers usually showed less gain in weight than the monkeys the milk intake of which was not as great. This may be a clue that the phenylalanine was near toxic levels at 2.75 gm. of amino-acid per kgm. body-weight per day. The fur coat of the animals was in all respects normal in colour and in quantity, and no abnormal skin lesions or delay in dentition were noted. Neurological examination revealed no sensory or motor abnormalities in these animals up to one year of age. Two of the four animals had typical grand mal convulsions at widely spaced intervals, and the monkeys usually slept for a short period following the seizure, but promptly recovered with no residual effects.

The psychological testing of each animal was begun shortly after the first week of life and consisted of: (1) delayed response tests; (2) discrimination learning set tests; (3) object discrimination tests; (4) Hebb-Williamson maze test, according to methods performed in this laboratory by Harlow⁵ and his associates. The total performance of the phenylketonuric animals was much below that of normal animals of the same age in all tests. It was quite clear that the retarded animals could not learn delayed response and discrimination learning set tests. These monkeys demonstrated motivational defects, inappropriate behaviour, subnormal learning, and sub-optimal intellectual performance.

An unusual opportunity for obtaining additional information on certain aspects of brain metabolism in mental retardation is thus provided by the production of phenylketonuria in a sub-human species. Work is now in progress to obtain information from monkey experiments so that treatment of phenylketonuria in human infants might be more satisfactory. The role of liver hydroxylase and brain decarboxylases on amino-acid metabolism can be thoroughly investigated in these animals. Further experiments designed to produce other types of retardation in monkeys are now under way.

RADIOBIOLOGY

Early Incorporation of Sulphur-35 Sodium Sulphate into Plasma Proteins of Man

IN investigating the fate of radiosulphate in multiple myeloma¹, the incorporation of sulphur-35 in human plasma protein fractions was investigated.

Carrier-free sulphur-35 as sodium sulphate in doses ranging from 0.867 to 2.07 mc. was administered intravenously to 10 patients with multiple myeloma and 14 patients with other neoplastic diseases. A patient with chondrosarcoma received labelled sulphate in three intravenous doses at weekly intervals of 505 mc., 391 mc., and 322 mc., respectively. (We wish to express our gratitude to Dr. C. Botstein, head of the Radiotherapy Dept., Montefiore Hospital, for making this patient available for study. The sulphur-35 for this patient was supplied by Abbott Laboratories.)

Sulphur-35 assays were made with a calibrated gas-flow counter and corrected for back-scatter and self-absorption. Blood samples were obtained at intervals during the initial 24 hr. and daily thereafter for the next 6 days.

Analysis of plasma proteins was performed with electrophoretic and staining techniques previously described². Simultaneously run filter paper strips were scanned for radioactivity in a suitably adapted gas-flow counter and exposed for 90 days to Kodak No-screen double-coated X-ray film for radioautography. Continuous curtain electrophoresis was performed on 1- to 3-ml. samples of plasma with standard techniques³.

In none of the plasma samples obtained from the myeloma patients and subjects with other neoplastic diseases was radioactivity demonstrable by scanning of the electrophoretic strips, radioautography, or continuous electrophoresis.

For the subject with chondrosarcoma, given more than 1 c. of sulphur-35 in 3 doses, however, progressive incorporation of sulphur-35 into the plasma protein fractions was readily detected after each dose by the assay of the electrophoretically separated proteins on the filter paper strips (Fig. 1). The relative distribution of sulphur-35 for the various protein moieties as a function of time is presented in detail for the initial therapeutic dose of 505 mc. (Fig. 2). Similar patterns were observed after each therapeutic dose. The albumin fraction promptly incorporated sulphur-35 with the maximum value reached in 4 hr. and thereafter showed a more gradual decline during 48 hr. Little further change was observed during the next 4 days. A slower incorporation of sulphur-35 with the maximum peak occurring in 18 hr. was noted for fibrinogen. The degradation was also slower than that of albumin, taking 4 days to reach minimum values. The α - + β -globulin fraction paralleled the fibrinogen curve at a lower level of radioactivity. Its peak-level was also reached in 18 hr. Little incorporation of sulphur-35 into γ -globulin was observed. However, it should be noted that this patient had a low concentration of γ -globulin. The highest level for this fraction was attained in 8 hr. and fell to base-line levels in 24 hr.

Sulphur-35 administered as sodium sulphate has been shown to be incorporated into the plasma proteins of animals⁴, but such incorporation has not been demonstrated in man. Reasons for this failure include: (1) Most of the sulphur-35 administered is excreted in the urine within 48 hr.^{1,5}. (2) The fraction of the dose remaining within the body is widely distributed in the sulphomucopolysaccharides of cartilage, aorta, sclera, cornea and intestinal mucosa⁶. (3) The maximum permissible dose of 2 mc. for this work was insufficient for the detection of radio-

Fig. 1. A, Paper electrophoretic strip stained for protein prepared from plasma obtained from chondrosarcoma patient 1 hr. following administration of 505 mc. labelled sulphate. B, Radioautograph of strip (94-day exposure); density corresponds to sulphur-35 activity. C, Relative distribution of activity along a strip determined by scanning with collimated gas-flow counter; adequate counts collected to assure 5-10 per cent accuracy.

Fig. 2. Variation of sulphur-35 activity in plasma protein fractions with time as derived from scans of corresponding electrophoretic strips.

activity in human plasma protein fractions, although even smaller amounts were found adequate for the rat⁴.

In the patient with chondrosarcoma, sulphur-35 was readily detected in all the plasma protein fractions after each therapeutic dose. The problem then arises as to how the sulphur-35 is bound to protein. One possibility is that the sulphur-35 is incorporated only into the protein-bound sulphated mucopolysaccharides. If this were so, the radioactivity would be distributed in the plasma protein fractions in proportion to the distribution of protein-bound polysaccharides. Indeed, this was found to be the case in the rat, where about 40 per cent of administered sulphur-35 sulphate activity was bound to a serum constituent having the electrophoretic mobility of α -1-globulin, suggesting that the binding occurs in a protein-bound sulphomucopolysaccharide⁷. However, the distribution of sulphur-35 in the plasma protein of the patient herein reported was not that of mucopolysaccharides. The greatest concentration of sulphur-35 was found in albumin and fibrinogen, indicating that the sulphur-35 was incorporated into the sulphur-containing amino-acids of the protein rather than the protein-bound mucopolysaccharides. This, of course, does not rule out some tagging of the sulphated mucopolysaccharides.

After oral administration of sulphur-35 labelled cysteine to man, the incorporation of the label into serum protein fractions has been shown to occur with great rapidity⁸. A striking similarity between our results using sulphur-35 labelled sulphate and those using the labelled amino-acid is noted. Thus, the albumin peak for sulphur-35 cysteine also occurred in 4 hr. and the α - + β -globulin peak at a time similar to ours. Of interest is the fact that the maximum for γ -globulin after labelled cysteine was low in a nutritionally normal patient, so the low values we observed may not be related necessarily to the hypogammaglobulinemia of our patient with chondrosarcoma. Furthermore, the ratios of the respective maxima to each other are almost identical for both studies. It would appear then that inorganic sulphate is rapidly bound to the various plasma protein fractions, presumably after first being incorporated into an amino-acid precursor. Also, the fact that our findings with sulphate parallel those done by others with labelled cysteine supports the view that sulphate is incorporated into the protein fractions, rather than

non-specifically bound. This is confirmed by our unpublished work in which we failed to demonstrate labelling of the plasma protein fractions after incubation with sulphur-35 labelled sulphate.

Plasma proteins contain functional SH groups and SH groups which are probably part of the cystine and cysteine molecules. Although there is little evidence to suggest that animal tissues can synthesize sulphur-containing amino-acids, there is good evidence that it does occur in animals and that this requires the presence of micro-organisms in the alimentary tract¹. The steps whereby the sulphur-35 of labelled sodium sulphate becomes incorporated into the sulphur-containing amino-acids of human plasma proteins are yet to be elucidated. This investigation demonstrates that it does occur. It is possible that in the human, as in lower animals, the activity of intestinal micro-organisms plays an important part. However, in the present work, one must postulate initial secretion of labelled sulphate into the bowel, directly or via bile, because all doses were given intravenously. The rapidity with which the incorporation of the inorganic sulphate into plasma protein occurs suggests that an alternative metabolic pathway may exist.

This investigation was supported in part by grant No. C-3438 from the National Cancer Institute, Public Health Service. The excellent technical assistance rendered by Mr. David Weinstein and Mrs. Lila Wolfman is gratefully acknowledged.

BIOLOGY

Sun Navigation by Birds

C. J. PENNYCUICK¹, discussing the physical possibility of an estimate of the change in azimuth of a celestial object by a bird, says: "Birds very often fly round in circles whilst orienting, and therefore cannot have their eyes stabilized in azimuth. The change in azimuth can therefore be measured only by reference to a fixed object [*sic*], when the bird is stationary on the ground. Over the sea it is not physically possible to measure it at all without some kind of compass. However, birds do navigate over the sea. Hence Matthews' hypothesis as it stands is untenable". Again in his summary: "Matthews' hypothesis . . . is rejected on the grounds of physical impossibility of making one of the measurements . . .".

Assertions about the physical impossibility of animal activities have so often proved false that they

should be closely scrutinized, and PennyCUICK's argument appears to be fallacious. What the bird needs is not a fixed object (in parenthesis it may be pointed out that a compass needle is not a fixed object) but an indication of a direction—any direction—in the horizontal plane lasting long enough (not more than a few minutes on Matthews's² hypothesis) to allow the change of azimuth of the celestial object to be measured. My experience of flying at a moderate height over the open sea is strictly limited; but I have never known an occasion when the sea could not be seen at all and when the necessary stable indication of direction could not have been obtained from the pattern of waves on its surface; in the belief that occasions when this indication is not available are exceedingly rare, I am confirmed by an experienced pilot of aircraft. It is therefore fair to assume that a flying bird could always obtain the necessary information in flight over the sea and that Matthews's hypothesis has not, on this ground, been invalidated.

PennyCUICK's own hypothesis, requiring only an appreciation of the Sun's elevation and of its rate of change, is attractive and economical, but it is surely unlikely that a bird should neglect information about the sign and magnitude of the Sun's rate of change of azimuth when this information, always available, could be used to increase the accuracy of estimate of its own position and to eliminate the ambiguity which can arise, according to PennyCUICK, in certain circumstances.

R. J. PUMPHREY

Department of Zoology,
University of Liverpool.

¹ PennyCUICK, C. J., *J. Exp. Biol.*, **37**, 573 (1960).

² Matthews, G. V. T., "Bird Navigation" (Cambridge Univ. Press, 1955).

It must be conceded that the rate of change of the Sun's azimuth could, in principle, be measured by reference to the orientation of the waves on the sea, but the possibility of using this method for navigation requires closer scrutiny. If it be assumed that the bird can use the maximum accuracy available, the problem falls into three parts:

(1) Within what limits can the direction of the waves be defined?

(2) Within what limits may its rate of change be deemed to be zero?

(3) To what distance on the ground does the minimum detectable change of rate of change of azimuth correspond?

It is to be hoped that someone better qualified than I will be able to produce definite information on the first two questions, but meanwhile some reasonable surmises may be made.

(1) The meaning of the "direction of orientation" of the pattern of waves on the sea would appear to be statistical in nature, the accuracy with which it could be defined increasing with the number of waves visible. The direction of the waves on a large stretch of sea seen from the air could clearly be defined within 10°, and probably usually within 1°. Whether it could be defined within 0.1° (1/5 of the diameter of the Sun's disk) is not so clear. In the following argument $\pm 0.01^\circ$ accuracy will be assumed, which is perhaps optimistic.

Large errors would occur in shallow waters owing to refraction of the waves in water of varying depth, so the use of the method would probably be confined to the open ocean.

(2) The limits within which the rate of rotation of the wave-pattern may be deemed to be zero (even when it really is zero) will depend on the above accuracy with which the direction of the wave-pattern can be determined, and also on the length of time available for observation. It would be logical to choose for the latter that time during which rate of change of azimuth changes by, say, 5 per cent, but to avoid complication, an observation time of 1 min. will be assumed arbitrarily. This has the effect of making changes of navigational accuracy from place to place appear greater than they really are, since in those regions where rate of change of azimuth changes rapidly with distance (good navigational accuracy) it also changes rapidly with time (short time available for observation). Also the best accuracy on the present assumptions is obtained when the Sun is high in the sky, which makes azimuth and changes thereof more difficult to observe. For the sake of argument let it be assumed that the rate of change of the Sun's azimuth can be measured by reference to the waves on the sea within $\pm 0.01^\circ/\text{min.}$ of time.

Apart from the problem of measurement, it is likely that an accuracy of this order would only be obtainable in regions of rather constant weather, such as the trade wind zones: such stability could probably not be relied upon in the North Atlantic, for example.

(3) If Z is the Sun's azimuth, L the observer's latitude, and H the local hour angle, it may be shown that, in the special case of equinox:

$$\frac{\partial Z}{\partial H} = \frac{1}{\operatorname{cosec} L \sin^2 H + \sin L \cos^2 H} \quad (1)$$

Fig. 1 is a diagram of lines of equal rate of change of azimuth, plotted for equinox. They form a family of closed curves meeting at the Sun's position. The points at which they cut the centre and edge of the diagram are calculated, but the shape in between is approximate.

The error of position for a given error of $\partial Z/\partial H$ is proportional to the spacing of these lines, that is, the rate of change of position with respect to $\partial Z/\partial H$. At noon ($H = 0$) we have:

$$\frac{\partial Z}{\partial H} = \operatorname{cosec} L$$

whence, differentiating up the Sun's meridian,

$$\frac{\partial}{\partial L} \left(\frac{\partial Z}{\partial H} \right) = -\operatorname{cosec} L \cot L \quad (2)$$

If the permissible error of $\partial Z/\partial H$ is $\pm 0.01^\circ/\text{min.}$ of time, or $\pm 0.04^\circ/\text{deg.}$ of hour angle, and the required accuracy of position finding is arbitrarily taken as ± 0.005 radian (17 nautical miles), then:

$$\operatorname{cosec} L \cot L = \frac{0.04}{0.005} = 8$$

$$L = 20^\circ$$

Fig. 1. Stereographic projection of the northern hemisphere, showing lines of equal rate of change of azimuth. The curves are approximate except that their intercepts on the noon and six o'clock lines are calculated. Dotted lines enclose zones in which particular accuracies of position finding could be obtained (see text)

The middle dotted line in Fig. 1 encloses the zone within which the required accuracy can be obtained. It crosses the meridian at $L = 20^\circ$, but the rest of it is drawn approximately. There is another mirror image zone south of the equator.

If the assumptions as to accuracy have been five times too optimistic, the zone comes up to 9° lat. (inner dotted line): if they have been five times too pessimistic, it comes up to 42° (outer dotted line). There is always a minute zone near the Sun within which any accuracy, however bad, will suffice.

It is hoped that the dubious assumptions in the above argument have been made explicit and will elicit informed comment. It seems likely that the method suggested by Prof. Pumphrey, while restricted in application, might very well provide navigational information to pelagic birds living in the trade wind zones. However, it would work best in roughly the same region where maximum accuracy can be obtained from rate of change of altitude, so it will not fill in any deficiencies in the system previously suggested.

It may be worth noting that observing the direction and speed at which the Sun moves across the sky, is equivalent to measuring the rates of change of altitude and azimuth, and no reduction in the accuracy requirements can be made by describing the process in one form rather than the other.

Reactions of Soil Nematodes to Coal-Tar Dyes

TESTS with dilute aqueous solutions of coal-tar dyes on soil nematodes reveal that reactions to 19 basic dyes of varied chemistry are of three classes.

Class I (absorption reaction), observed in many genera of the Enoplida, typically involves entry of the dye first at the anterior and then almost simultaneously at the posterior end of the nematode, with staining progressing toward the centre. Minimum

solution thresholds of this reaction range from 100 to 10 p.p.m. in 24 hr. Death occurs commonly; and in the stronger solutions is accompanied by intense accumulation of dye throughout the nematode corpus, obscuring internal structures. The reactions of all groups of soil nematodes to iodine fall into Class I. Minimum thresholds for iodine of both staining and toxicity in *Tylenchorhynchus martini* Fielding 1956 were between 10 and 1 p.p.m. in 24 hr.

Class II (basophilic reaction) has been observed in the genera *Tylenchorhynchus* (6 species), *Aphelenchoides* (2 species) and *Rhabditis* (2 species). This reaction manifests extreme sensitivity with minimum concentration thresholds ranging from 10 to 0.1 p.p.m. It is non-toxic, generally unaffected by solution pH and appears to be an adsorption phenomenon with staining intensities independent of dye concentrations. Each dye imparts a uniform tint of characteristic colour and intensity to the corpus, with the internal structures clearly visible. Staining occurs in 3-5 min. at dye concentrations between 10 and 1 p.p.m. and very rapidly at 100 p.p.m. The dyes appear to enter at all points on the nematode surface and the reaction is reversible in living nematodes. Stained specimens of *T. martini* placed in soil around rice plants for 7 days were re-isolated and examined. The dyes had disappeared from the corpus but were strongly retained by intestinal granules.

Class III (resistant reaction), in which there is little or no staining, has been observed in 9 known and 3 suspected phytophagous genera of the Tylenchida, in certain genera of the Rhabditida and in a *Plectus* sp. of the Chromadorida. Staining, when it occurs, is slight even at dye concentrations of 1,000 p.p.m. in 24 hr. and is largely confined to certain parts of the corpus, intestinal granules, sclerotized structures and inclusions of the body cavity.

The integrity of each class of reactions to basic dyes is maintained essentially in heat-killed and formalin-preserved nematodes, although breaking of resistance (Class III reaction) has been observed in some instances. Tests with 13 acid dyes on mixed populations of nematodes extracted from soils revealed, in comparisons with basic dyes, a more restricted spectrum of activity. Typical results, after 24 hr. in dye solutions of 200 p.p.m., show that approximately 10-fold more nematodes are stained by basic than by acid dyes.

Details of this work will be submitted for publication elsewhere.

Toxicity of Aluminium to Black Pepper (*Piper nigrum* L.) in Sarawak

SYMPTOMS of an unknown disorder have been increasingly observed on pepper vines since 1956; no pathogen seemed to be involved. Affected vines show an overall bright green to yellow colour and their leaves a pronounced droop. Individual leaves first show symptoms of a speckled necrosis mostly along the main veins, each brown spot having a surrounding yellow halo. Afterwards the necrotic areas spread and become more serious so that finally the leaves fall. These vines have a greatly reduced root system,

Fig. 1. The under-surface of detached pepper leaves showing a healthy leaf on the left and symptoms of increasing severity towards the right

which dies off centripetally. Different stages of the leaf symptoms are shown in Fig. 1.

Pepper vines are grown on low mounds in latosolic soils, which are poor in bases, particularly magnesium. The soil from mounds of affected vines was found always to be low in pH, generally below pH 4.5, and some mounds were as low as pH 3.5. Vines grown in soils of above pH 5.5 were unaffected. Analysis of soil from mounds of healthy and affected vines are given in Table 1.

Table 1. BASE AND ALUMINIUM CONTENT IN P.P.M. AND pH-LEVELS OF SOILS WITH AFFECTED AND UNAFFECTED VINES

	pH	Calcium	Magnesium	Aluminium
Unaffected vines (mean of 12)	5.6 (0.59)	2,529 (61.2)	84 (5.88)	91 (22.72)
Affected vines (mean of 25)	3.9 (0.39)	195 (91.7)	29 (3.91)	330 (15.21)

All differences are significant at $P = 0.001$. S.E. given in brackets

The cause of this disorder is apparently a toxicity of aluminium ions at low pH. These ions prevent the uptake of calcium and magnesium, leading to the deficiency symptoms of these elements, the yellowing and necrosis which appear in the pepper leaves. This free aluminium also causes the root systems to die, so that the foliage wilts, producing the characteristic droop. With the reduced uptake of calcium and magnesium, and a presumed reduction in the cation exchange capacity of the affected root system, the amount of potassium taken up actually increases, so that the ratio of $K/(Ca + Mg)$ can be used as a diagnostic index. The critical value appeared to be approximately 1.00. These effects are illustrated in the leaf analyses presented in Table 2.

Table 2. BASE CONTENT IN PERCENTAGE DRY MATTER, AND RATIO OF MONO- TO DI-VALENT CATIONS IN PEPPER LEAVES

Condition of vines	Calcium	Magnesium	Potassium	(K/Ca + Mg)
Unaffected (mean of 23)	1 1.363 (0.053)	4 0.231 (0.010)	7 1.450 (0.240)	10 0.930 (0.071)
Affected (mean of 18)	2 1.046 (0.060)	5 0.179 (0.013)	8 1.568 (0.270)	11 1.290 (0.081)
Seriously affected (mean of 12)	3 0.523 (0.082)	6 0.142 (0.014)	9 1.829 (0.310)	12 3.390 (0.029)

S.E. are given in brackets.

Differences significant at $P = 0.001$: 1 and 2, 1 and 3, 4 and 6, and 10 and 12.

Differences significant at $P = 0.01$: 4 and 5, 7 and 9, 10 and 11.

The recent apparent increase in this toxicity can be accounted for historically. After 1945 there was a tendency to abandon the traditional method of manuring pepper. This was to apply large quantities of burnt earth, supplying adequate bases to the mound. Gradually, relatively small quantities of processed organic manures and cheaper inorganic fertilizers have replaced the burnt earth. Presumably, therefore, the continual loss of bases and their inadequate replacement have led to a steady increase in soil acidity, which has now apparently reached a critical level.

Steps are being taken to continue this work and to provide remedial measures. Preliminary results indicate that the incorporation of magnesium limestone into the mound will prevent this toxicity.

The permission of the Director of Agriculture to publish these results is gratefully acknowledged.

Digestion of the Alga, *Macrocystis pyrifera*, by the Sea Urchin, *Strongylocentrotus purpuratus*

It has been known for some time¹ that sea urchins when fed and then starved seem to retain for long periods the food present in the intestine. Furthermore, *in vitro* experiments have shown that a battery of digestive enzymes exist, some of which can digest complex polysaccharides such as iridophycin¹ and algin². During a series of experiments on the digestion of various substrates by sea urchins we had occasion to feed and afterwards starve an adult urchin and then recover all the material remaining after digestion. So far as we are aware no evidence exists on the percentage of algal food that can be completely degraded to assimilable products by a sea urchin. An urchin was prestarved until no faecal pellets were passed. The animal, a female, weighing 99.3 gm., test height and test diameter measuring 26.5 mm. and 63.1 mm. respectively, was then fed a 33.3 mgm. (dry weight) piece of *Macrocystis pyrifera*, a food for which the sea urchin exhibits a high degree of preference³, and fed no further food for 18 days. The algal piece was consumed within 8 hr. No faecal pellets were passed during the observation time, and the animal was killed at the end of this time.

We removed the complete intestine of the urchin and recovered all the undigested materials. By comparison of the dry weight of the undigested residue with the dry weight of the food eaten, it is possible to determine the percentage of the alga that was digested, and, presumably, assimilated. 8.5 mgm. of undigested material was recovered, hence more than 76 per cent dry material of the alga was removed by the digestive processes of the urchin.

This completeness of digestion by a sea urchin supports the cited study on alginase since *Macrocystis* is known to contain at least 14.5–36 per cent dry weight of algin⁴. The extensive digestion of a meal when another is not forthcoming, coupled with the urchin's ability to resorb its gonads during starvation (Booolootian and Giese, unpublished work), may account for the urchin's ability to adapt itself to environments where food might become restricted.

This work forms part of a programme of investigation supported by funds from the National Science Foundation Grant 9561 to one of us (R. A. B.).

Biosynthesis of Arbutin from Some Phenylpropanoid Compounds in *Pyrus communis*

HIGHER plants are capable of synthesizing aromatic compounds from shikimic acid, possibly through a pathway similar to that described by Davis *et al.*¹. Certain benzene rings, however, are formed from acetate in accordance with the hypothesis of Birch and Donovan². Thus the B ring of quercetin is synthesized from shikimic acid³ whereas the A ring is an acetate-formed ring⁴.

Arbutin or hydroquinone- β -D-glucoside occurs in many plants, such as members of the Ericaceae, and accumulates to the extent of 0.05–0.17 per cent of the fresh weight of pear (*Pyrus communis* L.) leaves⁵. So far as we know there has been no report on the origin of the ring of hydroquinone. Gloor and Wiss⁶ have shown that mevalonic acid labelled with carbon-14 is incorporated by the rat into ubiquinone (a 2,3-dimethoxy-5-methyl benzoquinone with an isoprene side-chain of 50 carbon atoms). They have suggested that, whereas the isoprene side-chain is built up from mevalonic acid, the ring component is not synthesized by animals.

We have found that arbutin is synthesized in young leaves of pear from shikimic acid and more readily from phenylpropanoid compounds, whereas activity from acetate-¹⁴C, pyruvate-¹⁴C, and succinate-1,4-¹⁴C is not incorporated into arbutin under the same conditions of administration.

The methods used were as follows: ten leaf disks (diameter 1.2 cm.) were vacuum infiltrated with tap water, blotted and floated in a Petri dish in 1.2 ml. of a solution containing 1–2 μ c. of a radioactive compound. The covered Petri dish was placed under fluorescent lights for approximately 17 hr., after which the leaf disks were rinsed in tap water and extracted with boiling 80 per cent ethanol. The ethanol extract was concentrated, and chromatographed two-directionally in 80:20 phenol/water followed by 4:1:5 butanol/acetic acid/water. Radioactive spots were located by radioautography, and activity measurements were made by direct counting on the chromatograms. Arbutin, which is detected by its colour reactions with diazotized *p*-nitroaniline or diazotized sulphanilic acid, is well separated on chromatograms from chlorogenic acid and the other phenolics present in extracts.

Results of some of the feedings to pear tissue are given in Table 1.

Arbutin-¹⁴C obtained from a phenylalanine-U-¹⁴C feeding was hydrolysed with 2 N hydrochloric acid,

Table 1. INCORPORATION OF COMPOUNDS LABELLED WITH CARBON-14 INTO ARBUTIN IN LEAF DISKS OF *Pyrus communis*

Compound administered	Age of tissue (leaf disks)	Percentage of ethanol soluble activity in arbutin
Pyruvate-1- ¹⁴ C	young	0
Pyruvate-2- ¹⁴ C	young	0
Pyruvate-3- ¹⁴ C	young	0
Succinate-1,4- ¹⁴ C	young	0
Acetate-1- ¹⁴ C	young	0
Acetate-2- ¹⁴ C	young	0
Glucose-U- ¹⁴ C	young	0.8
Shikimic acid-U- ¹⁴ C	young	5
Phenylalanine-U- ¹⁴ C	young	12
Phenylalanine-U- ¹⁴ C	young	21
Phenylalanine-U- ¹⁴ C	mature	0
Phenylalanine-U- ¹⁴ C	dormant leaf buds	12
Phenylalanine-3- ¹⁴ C	young	0
Tyrosine-U- ¹⁴ C	mature	0
Tyrosine-U- ¹⁴ C	young	8
Cinnamic-ring, 3- ¹⁴ C	mature	0
Cinnamic-ring, 3- ¹⁴ C	young	29
Benzoic acid-1- ¹⁴ C (ring labelled)	young	0

after elution from the chromatogram with cold ethanol, and the products chromatographed in the butanol/acetic acid/water solvent. Hydroquinone-¹⁴C was identified by its R_F value and colour reaction, which were the same as those of standard hydroquinone. Arbutin-¹⁴C obtained from the feeding of glucose-U-¹⁴C was hydrolysed in the same way to give non-radioactive hydroquinone together with glucose-¹⁴C.

Phenylalanine-U-¹⁴C fed to *Grevillea robusta* A. Cunn. was also incorporated into arbutin, confirming the results obtained with pear. In this species, however, the age of the leaf did not appear to be an important factor. In pear, chlorogenic acid was the major compound labelled with carbon-14 obtained when phenylalanine-U-¹⁴C was fed, but no radioactive chlorogenic acid was obtained with *Grevillea*. According to Bate-Smith, chlorogenic acid does not occur in *Grevillea* (personal communication).

It is not known at present whether tyrosine gives rise to the hydroquinone or the glucose moiety of arbutin or both. It is known to form sugars readily when fed to pear leaves maintained in light.

It is evident, therefore, that hydroquinone may be formed in young pear leaves by the removal of the C₃ side-chain of certain phenylpropanoid compounds such as cinnamic acid, phenylalanine, and possibly tyrosine. This, together with the fact that it is not formed from acetate, indicates that it is an aromatic compound formed via the shikimic acid route.

This work is to be published in detail elsewhere.

We wish to thank the National Research Council of Canada for financial support of this project. We also thank Dr. E. E. Conn of the University of California, Berkeley, for a generous gift of ring and 3, carbon-14-labelled cinnamic acid.

ENTOMOLOGY

A Tick infesting the Nostrils of Man

AN interesting example of the necessity for co-operation in the solution of complex problems of tick bionomics was recently brought to my notice by Dr. V. G. L. Van Someren of Nairobi and concerns infestation of the nostrils of man by the immature nymph stage of a tick belonging to the genus *Amblyomma*. These nymphs are white and were removed from the nostrils of three different persons, namely, Mr. D. Van Someren, Dr. V. G. L. Van Someren and Mr. T. H. E. Jackson, during visits to the depths of primary tropical rain forest in Uganda. The two former-mentioned persons were infested while in the Budongo Forest of Bunyoro during July 1952; the two latter while in the Kayonza Forest of Kigezi (known also as the Impenetrable Forest) during May and June 1957. A single example of the same tick was also found by Dr. Van Someren as it crawled up his neck when in the Kibali Forest of Toro.

It is of interest to note that these highly experienced entomologists were never aware of the ticks crawling across their faces or entering their nostrils. The first indication of infestation was tenderness of the nose when touched or when blown. Equally interesting was the absence of irritation or epistaxis and the disappearance of tenderness within a few hours of removal of the ticks. This almost complete absence of reaction to the presence of the parasite in man when acting as alternative host might suggest that nymphs of these ticks normally infest the nasal passages of anthropoid apes (Pongidae). The chimpanzee (*Pan troglodytes* sub. sp.) is in fact common in these Uganda forests.

Examples of these nymphs removed from human nostrils in the Kayonza Forest were examined and compared with all known African *Amblyomma* nymphae by Dr. Gertrude Theiler of the Veterinary Research Laboratory, Onderstepoort, Transvaal, Union of South Africa, Miss Jane Walker of the East African Veterinary Research Organization, Muguga, Kenya, and by Dr. Harry Hoogstraal, head of the Department of Medical Zoology, U.S. Naval Medical Research Unit No. 3, Cairo, Egypt. Although all three specialists were unable to identify these nostril ticks, it is suggested by Miss Walker that they may be the nymph stage of *Amblyomma paulopunctatum* Neumann, 1899, which in the mature stage is known to be a parasite of the giant forest hog (*Hylochoerus meinertzhageni*) in western Uganda and distributed in equatorial Africa from French Guinea to Uganda.

Anyone hunting in or visiting the Uganda or West African forests could assist the identification of these ticks by examining the nasal passages of mammals, watching for any white ticks falling from the nose of captured chimpanzees or, when aware of nasal tenderness, allowing the ticks to remain *in situ* until engorged with blood and approximately the size of a small pea, when they may become detached and be blown out into a handkerchief or gently removed with forceps. The ticks should not be killed or put in spirit, but should be kept alive in a tin or tube stuffed with moss or moist tissue paper with a piece of rag tied over the top and posted to one of the specialists mentioned above. In man these ticks become attached to the nasal septum or upper anterior recess of the anterior nasal chamber.

I am indebted to Dr. Van Someren for his detailed observations and wish to thank Dr. G. Theiler, Miss J. Walker and Dr. Harry Hoogstraal for examining Dr. Van Someren's specimens.

Atypical Spermiogenesis in *Thermobia domestica*, a Thysanuran Insect

SPERM formation of a thysanuran, *Lepisma domestica*, has been repeatedly investigated by a number of workers¹⁻⁵. Unfortunately, diverse opinion prevails on the basic morphology of this sperm.

It is pertinent to recall that Bowen² and Nath and Bhatia⁵ find *Lepisma* sperm to be unique inasmuch as the funnel-shaped acrosome lies at the posterior and centriole at the anterior end of the elongated nucleus. Nath and Bhatia add further that the mature sperm is devoid of mitochondrial material. On the other hand, Gatenby and his associates, in a number of earlier publications on *Lepisma* and a recent study⁶ on another thysanuran, *Pterobius maritimus*, disagree with the interpretation of Bowen, Nath and Bhatia. In view of these contradictory reports, the present work⁷ was undertaken to investigate, employing classical and modern cytological techniques, not only the morphology but also cytochemistry of spermiogenesis in another genus, *Thermobia domestica*. I agree with the assumption of Gatenby and Mathur that the insects (*Lepisma domestica*, *Pterobius maritimus*) and *Thermobia domestica* so closely allied could not have spermatozoa basically different in construction.

The investigations on *Thermobia domestica* confirm the view that thysanuran sperm is atypical in having a funnel-like acrosome in an unusual position behind

the nucleus and the centriole at the anterior end of the latter. The identification of the acrosome as a 'post-nuclear' funnel is further strengthened by the observations that it is periodic acid-Schiff positive and that it arises in connexion with the fusion of the dictyosomes. The mitochondrial development is of the usual insect type. Unlike *Pterobius maritimus*, a single rod-like centriole, as observed in the living cells under the phase-contrast microscope, moves around the nucleus, and the acrosome, once deposited on the latter, continues to occupy the basal end of the metamorphosing spermatozoon. Electron microscope study (Fig. 1) reveals, apart from many new features, that the tail flagellum (AF) along with the mitochondrial sheath (MN) runs adjacent to the nucleus (N). This situation can only be interpreted if the centriole from which the tail is always considered to emerge lies at the head end of the developing spermatozoon. The 'lateral fold' of the nucleus in *Pterobius*⁶ is most probably the backward continuation of the flagellum.

BACTERIOLOGY

Germination of Bacterial Spores by Long-Chain Alkyl Amines

SURFACE-ACTIVE agents induce striking changes in the physical, chemical and biological properties of bacterial spores^{1,2}. The alterations caused by selected quaternary ammonium compounds are relatively minor at room temperature, but rapid and large at 50-100° C. The changes in spores of *Bacillus megaterium* brought about by combinations of mild heat and the quaternary ammonium compounds studied were practically identical with germinative changes induced by L-alanine and inosine^{3,4} except that the cells treated with surfactants were non-viable². In all probability this class of surfactants induced germination, the germinated spores being hypersensitive to the concentrations of surfactants required for germination and being killed immediately on germination.

Germinative changes in spores brought about by non-metabolites has been called 'chemical germination' in contradistinction to 'physiological germination'^{2,5} effected by amino-acids and ribosides, etc. Germinative changes in spores accompanied by loss of viability (loss of ability to form colonies on agar media) may be regarded as 'lethal germination'.

Chemical germination of spores of *B. megaterium*, whereby germinative changes are accompanied by retention of viability, has now been achieved with long-chain alkyl primary amine surfactants.

Fig. 1. $\times 6,000$

L-Alanine, inosine or other physiological germnants are not essential in this system, nor is heat shock*. For optimal physiological germination of these spores heat shock combined with L-alanine and inosine or adenosine were found to be essential.

n-Dodecylamine [$\text{CH}_3(\text{CH}_2)_{10}\text{CH}_2\text{NH}_2$] was added to a suspension of spores of *B. megaterium* (approximately 6×10^7 spores per ml.) in 0.067 M phosphate buffer, pH 8.0. Final concentration of the dodecylamine was 0.00006 M. The following changes took place within a few minutes at 42° C.: (1) The normally refractile spores lost their refractility as determined by phase-contrast microscopy. (2) The spores became readily stainable with crystal (gentian) violet. (3) The spores were somewhat enlarged. (4) There was a marked reduction in the optical density (at 500–570 mμ) of the spore suspension (Fig. 1). (5) The majority of the cells in the suspension were capable of forming colonies (Fig. 1) on a complete agar medium* after neutralization of the dodecylamine with cephalin as described by Baker *et al.*†. (6) The surviving cells were not resistant to heat (Table 1). Likewise, they were killed by a variety of physical and chemical stresses which were lethal to spores germinated physiologically, but which were essentially innocuous to normal ungerminated spores (Table 1). (7) The spores lost more than 30 per cent of their dry weight. (8) The spores discharged their dipicolinic acid which appeared in the

Table 1. SURVIVAL OF SPORES OF *B. megaterium* GERMINATED WITH DODECYLAMINE

† Cells were frozen with a mixture of dry ice and acetone and thawed with running tap water in rapid sequence a total of eight times.

† Cells were exposed for 2 min. to aqueous solutions of these chemicals, then diluted rapidly and plated to recovery medium.

Fig. 1. Chemical germination of spores of *B. megaterium* with 0.00006 M dodecylamine, temperature 42° C. Curve A denotes survivors which formed colonies on a complex agar medium. Curve B denotes survivors which were able to tolerate heating at 65° C. for 20 min. Note that after 1-min. exposure to dodecylamine 90 per cent of the total viable survivors had become sensitive to heat. The dodecylamine was not lethal to the spores until after 3 min. Curve C shows that dipicolinic acid was released from the spores by dodecylamine prior to loss of viability but at a rate slower than the rate of labilization to heat. Curve D shows the typical reduction in optical density which accompanies germinative changes in bacterial spores.

suspending liquid (Fig. 1). An excretion of calcium and of a peptide which contained hexosamine was also observed. (9) Finally, the spores treated with dodecylamine exhibited an increased respiration at the expense of added glucose; they also had a definite low endogenous respiration. Ungerminated spores had a negligible respiration either in the presence or absence of glucose.

Since all the above features are characteristic of spores which have been germinated either physiologically or mechanically*, it seems logical to conclude that true germination took place in the presence of dodecylamine and that this represents chemical germination in the sense described above. Other straight-chain primary amines displayed the germinative properties to varying degrees.

Some preliminary experiments were undertaken to determine whether germination by dodecylamine involves enzymes. Dodecylamine induced a germination-like decrease in optical density, a loss of refractility, a conversion to stainability and a release of dipicolinic acid under the following unphysiological conditions: at an incubation temperature of 70° C., at a pH of 11, in a solution containing 10 per cent ethyl alcohol, 15 per cent hydrogen peroxide, 1 per cent phenol or 1 per cent sodium cyanide, respectively. Presumably, any enzymes which might be activated by dodecylamine to elicit the germinative changes would be located near or at the surface of the spore, hence would not only have to persist throughout dormancy of the spore but also would have to be active in all the physiological extremes mentioned above.

The non-enzymatic evidence presented here extends the support* for the concept* that the prime event in germination is a breaching of a permeability barrier in the dormant spore which permits an ingress of water and attendant rehydration of the vital spore constituents.

A point of major interest now is to determine how the physiological germinants L-alanine and inosine fit into the picture and whether or not they have a function in a non-enzymatic or enzymatic mechanism for rehydrating the bacterial spore.

This work has been supported in part by a grant from the Office of Naval Research.

An extended account of these and related experiments will be published elsewhere.

VIROLOGY

Polyoma Virus in Syrian Hamsters: a Non-communicable Infection

EPIZOOTICS caused by polyoma virus have been reported^{1,2} in mouse colonies maintained in proximity to mice infected experimentally with this virus. Establishments without facilities to house infected and uninfected mice in separate buildings run the risk of contaminating their polyoma-free stock. It was of interest to determine, therefore, whether similar problems would be encountered when the Syrian hamster was used as the experimental animal to study this disease. Our experience indicates that infected hamsters rarely transmit polyoma virus to other hamsters or mice. The evidence that polyoma infection is a much less contagious disease of hamsters than of mice is shown by the following experiments.

(1) Hamsters less than 24 hr. old were divided into three groups and injected subcutaneously in the interscapular region with either $10^{4.5}$ mouse embryo tissue culture doses (TCID₅₀) of polyoma virus, $10^{2.5}$ TCID₅₀, or sterile diluent fluid. The hamsters were appropriately marked and distributed among 13 mothers so that each litter contained 2-4 animals from each group. The hamsters were weaned and placed in separate cages when they reached 21 days of age. Approximately half the hamsters were bled between 41 and 59 days of age. Autopsies were performed on all hamsters dying during the experiment. At 98 days of age the surviving animals were bled, killed and autopsied. The sera were tested by hemagglutination-inhibition and complement fixation for the presence of antibody to polyoma virus as described elsewhere³. As shown in Table 1, there is no evidence that any of the litter-mates injected with sterile diluent fluid contracted infection with polyoma virus.

(2) During assays of tumour-inducing capacity of polyoma virus in hamsters, approximately 200

suckling animals and more than 400 weaned animals were housed at the same time in nursing or individual cages in a single room with a floor area of 900 sq. ft. The hamster cages were arranged in series on long tables according to the age of the animals. To test whether the virus could spread from hamsters to mice, 7 cages each containing 5 young (8-10 gm.) mice were distributed in the room, some adjacent to cages occupied by suckling hamsters recently injected with polyoma virus, some among 21-50-day-old infected hamsters, and others among cages containing infected animals older than 90 days of age. The mice were bled twice, at 40 and 96 days, after being placed in the environment with infected hamsters. During this time all cages were cleaned and changed as needed, and all other usual activities permitted in the room. All the sera of the mice were negative when tested by hemagglutination-inhibition and complement fixation. Careful gross inspection of the mice killed at 96 days after exposure to infected hamsters failed to reveal the presence of tumours.

(3) To achieve randomization in experiments with polyoma virus in new-born hamsters, we have distributed our inoculated hamsters so that each litter contained animals injected only with control diluent fluid as well as animals injected with various test dilutions of virus. To date, we have studied nearly 2,500 animals of which 320 were injected at birth with non-infectious materials. From autopsies and serological tests on individual sera it became apparent that only two hamsters injected with non-infectious material at birth showed evidence of infection at the time the experiments were terminated. Although we suspect that they contracted the infection from their litter-mates, we cannot exclude the possibility of error made at the time the inoculum was administered.

Several factors probably account for the non-contagious nature of polyoma infection in hamsters as compared with mice. Mice infected with polyoma virus excrete virus in urine, and cross-infection probably takes place through inhalation of aerosols^{1,2}. Hamster urine is considerably less copious, and because of their habits they are less prone to create aerosols. Moreover, virus might be lacking in their urine since polyoma virus multiplies poorly in hamsters albeit tumours are readily induced. This is evident from the finding that only a fraction of tumours induced by cell-free filtrates contain demonstrable virus⁴. Occasionally, hamsters with tumours lack demonstrable antibody⁵.

The results indicate that, with minimal care, laboratories doing research with polyoma virus in Syrian hamsters should not have much difficulty in keeping their small animal stock from becoming infected.

This investigation was aided by a grant from the U.S. Public Health Service (C-4204).

FORTHCOMING EVENT

Thursday, December 29

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 3 p.m.—Dr. V. E. Coslett: "Seeing the Very Small". (The One Hundred and Thirty-first Course of six lectures adapted to a Juvenile Auditory. Further lectures on December 31, January 3, 5, 7 and 10.)

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN ASTRONOMY—The Registrar, The University, Manchester 13 (December 31).

GRADUATE CHEMIST or PHYSICIST at the Houldsworth School of Applied Science, for a two-year programme of research on the physical and chemical properties of clays, particularly those used in the manufacture of building brick and heavy clayware—The Registrar, The University, Leeds 2 (December 31).

LECTURER (suitably qualified science graduate) IN DENTAL MATERIALS, to assist in the teaching of dental students and to undertake research in the physical, chemical and mechanical properties of plastics, elastomers, ceramics, alloys and other materials used in restorative dentistry—The Secretary, The London Hospital Medical College (University of London), Turner Street, London, E.1 (December 31).

RESEARCH WORKER (with some training in physics and mathematics) IN THE DEPARTMENT OF GEOGRAPHY, to assist the Lecturer in Polar Studies in a project concerned with the analysis of heat and water transfer in a river and a glacier basin—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (December 31).

SENIOR LECTURER IN MATHEMATICS; a LECTURER IN OPHTHALMIC OPTICS; and a LECTURER IN MATHEMATICS OR STATISTICS—The Bursar, College of Advanced Technology, Gosta Green, Birmingham 4, quoting "N" (December 31).

EXPERIMENTAL OFFICER (graduate) IN THE DEPARTMENT OF CHEMISTRY, with responsibility for the maintenance of electronics apparatus—The Registrar, The University, Leicester (January 7).

ASSISTANT (medically qualified for at least three years and interested in human genetics and epidemiology)—The Director, Population Genetics Research Unit, Medical Research Council, Old Road, Headington, Oxford (January 14).

TUTOR (graduate in physics or chemistry or mathematics) IN THE INSTITUTE OF EDUCATION—The Registrar, The University, Hull (January 14).

LECTURER IN COAL PREPARATION IN THE DEPARTMENT OF MINING AND MINERALS ENGINEERING—The Registrar, The University, Edgbaston, Birmingham 15 (January 15).

PSYCHOLOGIST (with an honours degree in psychology or its equivalent) IN THE DEPARTMENT OF SOCIAL ANTHROPOLOGY, to assist in a study of urbanization and the effects of industrialization which the Department is conducting in Sierra Leone, West Africa—Dr. Kenneth Little, Department of Social Anthropology, University of Edinburgh, 3 Buccleuch Place, Edinburgh (January 15).

SCIENTIFIC OFFICER (with at least a good honours degree in geography, with subsidiary zoology and/or botany, or in zoology, with subsidiary geography, and preferably some experience in biogeographical, bioclimatic or ecological research) IN THE GEOGRAPHICAL SECTION, for research in the biogeography and ecology of economically important locusts and grasshoppers—The Director, Anti-Locust Research Centre, 1 Princes Gate, London, S.W.7 (January 16).

PROFESSOR OF MICROBIOLOGY, to take charge of the Department of Microbiology within the School of Biological Sciences, The University of New South Wales—The Agent-General for New South Wales, 56-57 Strand, London, W.C.2 and The Bursar, University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia, marking envelope "University Appointment" (January 23).

LECTURER or ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, The University, Leeds (January 24).

ASSOCIATE PROFESSOR (with a higher degree and preferably specialized in the field of feedback control systems) IN ELECTRICAL ENGINEERING at the University of New South Wales—The Agent-General for New South Wales, 56-57 Strand, London, W.C.2, and the Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia, marking envelope "University Appointment" (January 27).

SENIOR LECTURER, and a LECTURER IN GEOLOGY at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 27).

BRITISH COKE RESEARCH ASSOCIATION FELLOW (honours graduate in chemistry, physics or applied science relating to fuel technology), to work on the physical chemistry of carbon under the direction of Prof. W. F. K. Wynne-Jones—The Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (January 31).

ELDER CHAIR OF PHYSICS in the University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

LECTURERS (2) IN PHYSICS at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 31).

LECTURERS (2) IN ZOOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 31).

CHAIR OF LOGIC—The Secretary of University Court, The University, Glasgow (February 3).

SENIOR LECTURER (with a higher degree or equivalent qualifications) IN PHYSICS at the Newcastle University College, The University

of New South Wales—The Agent-General for New South Wales (Dept. HH), 56-57 Strand, London, W.C.2, and the Appointments Section, The University of New South Wales, Box 1, Post Office Kensington, N.S.W., Australia (February 3).

LECTURER IN THE SCHOOL OF MINERALS ENGINEERING—The Registrar, The University, Edgbaston, Birmingham 15 (February 15).

SENIOR LECTURER or LECTURER IN STATISTICS at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, February 15).

CHAIR OF APPLIED MECHANICS tenable in the Newcastle Division—The Registrar, University Office, 46 North Bailey, Durham (February 18).

CHAIR OF PHYSICS tenable in the Newcastle Division—The Registrar, University Office, 46 North Bailey, Durham (February 18).

LECTURER IN PHILOSOPHY at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, February 18).

IMPERIAL CHEMICAL INDUSTRIES FELLOW IN ONE OF THE FOLLOWING SUBJECTS: CHEMISTRY, BIOCHEMISTRY, PHYSICS, ENGINEERING, CHEMOTHERAPY and related subjects—The Secretary, Academic Council, The Queen's University, Belfast (March 1).

ELECTRONICS TECHNICIAN, to undertake the construction, development and maintenance of electronic and electrical equipment used in the physiological and radiological fields of medical research—The Secretary, Nuffield Institute for Medical Research, 48 Woodstock Road, Oxford.

LECTURER (single man) IN AGRICULTURAL BOTANY (AND ASSISTANT WARDEN)—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, near Chelmsford, Essex.

LECTURER (well qualified, with industrial and teaching experience) IN ELECTRICAL ENGINEERING at the Norwich City College and Art School, Ipswich Road, Norwich—The Director of Education, City Hall, Norwich, NOR 01 A.

LECTURER (with an honours degree and teaching experience, and preferably with higher degree and evidence of research ability), to TEACH PHYSICAL CHEMISTRY to B.Sc. General (New Regulations), Grad.B.I.C. and H.N.C. standards—The Clerk to the Governors, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

LECTURER (with good academic qualifications in mathematics, and either experience of or an interest in numerical analysis) IN MATHEMATICS in the Department of Science, Bournemouth Municipal College of Technology and Commerce—The Chief Education Officer, Town Hall, Bournemouth.

MARINE BIOLOGIST (with a good honours degree in natural science, and preferably experience in marine research) with the Fisheries Development and Research Unit, Sierra Leone, for research into problems connected with the development of the marine and freshwater resources of Sierra Leone and biological investigations designed to assist in the conservation of the trawl fishery—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/15/01.

POSTDOCTORAL RESEARCH FELLOWS IN THEORETICAL PHYSICS—L. E. H. Trainor, Physics Department, University of Alberta, Edmonton, Alberta, Canada.

RESEARCHER (with the qualifications and experience to direct research and postgraduate work, and to take a leading part in advanced teaching) IN PHARMACOLOGY—The Registrar, Bradford Institute of Technology, Bradford 7.

RESEARCH ASSISTANT (suitably qualified in biochemistry, pharmacology or zoology) IN THE WELLCOME LABORATORIES OF PHARMACOLOGY The Gatty Marine Laboratory, St. Andrews, for work on thyroid metabolism of lower vertebrates—The Joint Clerk to the University Court, College Gate, St. Andrews.

RESEARCH FELLOWS and RESEARCH ASSISTANTS (with an honours degree in pharmacy or other allied subjects) IN THE DEPARTMENT OF PHARMACY—The Registrar, Bradford Institute of Technology, Bradford 7.

SCIENTIFIC ASSISTANT (with an honours degree or its equivalent in biological sciences, preferably including physiology; a knowledge of languages, especially Spanish; and the ability to write correct English), to work on literature for *Nutrition Abstracts and Reviews*—The Director, Commonwealth Bureau of Animal Nutrition, Bowett Research Institute, Bucksburn, Aberdeen.

SCIENTIFIC OFFICER (CHEMIST), and an ASSISTANT EXPERIMENTAL OFFICER (CHEMIST)—The Secretary, Room 166(L), New Scotland Yard, London, S.W.1.

SENIOR LABORATORY TECHNICIAN (Grade I)—The Hospital Secretary, Harefield Hospital, Harefield, Middlesex.

TEACHING ASSISTANTS IN THE DEPARTMENT OF CHEMISTRY—Prof. Harry B. Gunning, Head, Department of Chemistry, University of Alberta, Edmonton, Alberta, Canada.

COLLEGES OF ADVANCED TECHNOLOGY

THE Advisory Council on Scientific Policy in its last report expressed the opinion that the development of colleges of advanced technology in Britain and the expansion of the smaller or medium-sized universities, which have hitherto included only faculties of arts or pure science, afforded an opportunity unlikely to recur for promoting studies in fields where there is little or no tradition of research and its application, and where there is little interaction between the universities and the industries which are the customers for the resulting technological skills. In the subsequent debate on the Council's report in the House of Lords, the question of research in the colleges of technology was scarcely mentioned, but in speaking on educational policy in the House of Commons on November 7, the Minister of Education, Sir David Eccles, after referring to the steady growth of postgraduate work in these colleges which the Government proposes to encourage as much as possible, said that he is very keen that these colleges should vigorously develop applied research.

Sir David expressed the view that the colleges of advanced technology are excellently placed to do so, because of their close links with industry; and those links would undoubtedly assist in the selection of projects for research that are really worth while. This appears to be what the Advisory Council on Scientific Policy also has in mind, but it is not here that the real difficulties in encouraging research in technical colleges lie. They are to be found in relation to staff, to problems of administration and status, and to a certain extent in finance. These difficulties, however, were not considered in the debate, though Mr. A. Albu doubtless had them in mind when he urged that the colleges of advanced technology should have independent governing bodies and should not come under the local authorities.

How small is the comparative contribution from the colleges of advanced technology may be seen from some figures quoted by Dr. D. C. Freshwater in *Technology*. Against an estimated 6,000 postgraduate workers in science and technology in the universities, there are only some 200 scientists and technologists on full-time postgraduate research in these colleges, of whom 40 are financed by Government grants, 20 by awards through the Department of Scientific and Industrial Research and 140 by the local education authorities. Of these 200, some 120 are in colleges in the London area and only about 80 in the remainder of the country, including those industrial areas of the Midlands and the North where it might be expected that close contact with local industry would be most conducive to stimulating exactly the type of technological research that the Advisory Council on Scientific Policy suggested in its last report.

Any advantage that the colleges of technology may enjoy through closer relations with local industry

in the selection of projects for research, and possibly for the conduct of such research, can be more than offset if the conditions these colleges offer are not such as to attract staff of the requisite quality or to retain competent postgraduate students. The function of the colleges of technology in advancing knowledge, especially knowledge of value to industry, is still insufficiently recognized, and not all local authorities responsible for such colleges appreciate that research can make an important contribution in the teaching of advanced students, the vitality it imparts to the instruction being as important here as in a university. There are still local education authorities which do not acknowledge research as a normal and indeed an important function of the technical colleges. In consequence, there is no general pattern to the scope and practice of research in progress at the present time; and even where it is formally recognized, lack of facilities and equipment is an obstacle to the postgraduate research student, and the lecturer may find difficulties in giving time to research as distinct from teaching.

In a recent article in the *Journal of the Royal Institute of Chemistry* (84, 235; 1960), Dr. D. E. Chisman describes the position more particularly with regard to chemical research, which is believed to be in progress to some extent in at least forty colleges, or about half the technical colleges recognized by the Institute for training candidates for the graduate membership examination. In two of these there are more than fifty research workers in the chemistry department; but this includes part-time and full-time workers, both for the teaching staff and research students. In a further five colleges there are between 25 and 50 research workers; but in most of the colleges there are fewer than ten research workers, sometimes just one or two members of the staff who are endeavouring to complete research projects started elsewhere. Altogether, Dr. Chisman suggests that in the technical colleges in 1959-60 there were more than 300 chemistry research projects under way.

Again, the facilities available for research vary widely. Sometimes the only space available is in a corner or at one end of a teaching laboratory. Elsewhere small rooms have been partitioned off from large laboratories; but in a few colleges the facilities have been appropriately designed, and an area up to 3,500 sq. ft. is available, though the usual area specifically available where a research laboratory is provided seems to be about 1,000 sq. ft. Especially in the smaller colleges, research in chemistry is at present undertaken only by members of the teaching staff, and their research interests have to be integrated with their teaching duties. If the latter are particularly onerous, the time for research is naturally curtailed, and the research project at best is protracted, if indeed it is ever completed.

To help members of staff who have genuine research projects in train, many local education authorities are prepared to allow some time for research in lieu of teaching duties, and according to Dr. Chisman this usually amounts to 3-6 hr. a week, although for a reader or principal lecturer it may be 12 hr. per week. Not all local authorities, however, appreciate the desirability of allowing teaching staff time for research, and Sir David Eccles's observation in the House of Commons should induce some improvement here, though it is reasonable to expect that the teaching staff concerned should display some initiative and enthusiasm, and disclose the nature of their projects. The brochure issued by the London and Home Counties Regional Advisory Council for Higher Technological Education on research in progress in technical colleges of the region, for, or in collaboration with, industry, Government departments and research associations indicates the range and value of such projects even in 1956.

One disappointing feature of the present situation to which Dr. Chisman refers is the comparatively small number of students of research calibre, to whom research studentships in science and technology have been awarded through the Department of Scientific and Industrial Research, who elect to receive their training in technical colleges. There are at present more than 2,000 such awards held in universities and technical colleges in Britain, and it is expected that about a further 1,000 awards will be made this year. Less than 2 per cent of such research studentships in 1958 were for tenure in technical colleges, mostly in chemistry.

Some, but not all, research in colleges of technology is undertaken for the purpose of obtaining a higher degree or equivalent qualification, and the new award of membership of the College of Technology, introduced by the National Council for Technological Awards, which will normally be made for a programme of work (not necessarily research) carried out jointly in industry and at a college, should assist in removing any difficulties which research workers at the colleges of technology may experience in obtaining a higher qualification. While the College of Technologists will expect a high standard of candidates, the award will not be restricted to holders of the diploma in technology. Here there is, of course, a time factor: the award has to establish its merits, and this might perhaps be the easier if there were less readiness to blur the distinction between colleges of technology and the technical colleges. To say the least, it is debatable how far postgraduate work is really practicable in an institution which is not devoted to instruction at university-level.

Dr. Chisman expresses the opinion that there are probably in the colleges of technology more *ad hoc* short-term research projects in progress at any given time than research designed specifically for a higher degree or equivalent. Local industrial needs often lead to the initiation of short-term special research problems, thus effecting a valuable link between industry and technical education. Moreover, industry

can, and does, assist by giving expensive equipment, and some colleges have thus been able to develop useful specialized research facilities. This is obviously a step towards the co-operation in the attack on major technological problems which the Advisory Council on Scientific Policy had in mind in its last report. If the major colleges of technology are to develop schools of research in particular technological fields, it will be just as essential that the immensely expensive equipment, which technological research no less than scientific research requires, shall be used on an agreed co-operative basis—perhaps between such colleges themselves, or between a particular college or group of colleges and industry—as it has now become for the universities.

Developments along such lines are likely to provide one of the surest ways of winning the prestige that will enable the colleges to attract—and keep—all the research workers they are able to accommodate. They will also help to solve the problem of status; but it must be realized that the question of status and autonomy cannot be left to chance. They must be tackled simultaneously and urgently. Research workers of the requisite calibre will not be drawn to the colleges of technology unless they are assured of a status comparable with that which they would enjoy in a university institution, and have the freedom to teach and investigate which it is a primary function of academic autonomy to ensure. The independence of the colleges of technology is a problem which needs urgent consideration, and local interest should not be allowed to overrule the national interest. Given goodwill and understanding and sense, the reconciliation of a live interest in local institutions with the larger national concern should prove no more difficult than in the creation of new university institutions.

One final aspect of research noted by Dr. Chisman might well make a valuable contribution to this problem, as well as to the prestige of the colleges. Dr. Chisman refers to the need for investigations into methods of presenting the subject-matter used by lecturers in the technical colleges. As he rightly points out, the rapid developments of the past few years in the understanding of many phenomena through modern theories of atomic and sub-atomic structure have spurred the abler teachers to re-appraise their systems of teaching and to introduce substantial modifications, leading to more logical and co-ordinated presentation and to a more comprehensible and sound basis for further study. The whole content of university science courses as well as of school courses is under challenge and re-examination. There are also numerous ways in which standard experimental techniques may be improved and new demonstration techniques devised to illustrate theoretical topics. The colleges of technology may, in fact, enjoy more flexibility to take advantage of the considerable scope for such work, especially in the field of small-scale equipment; and in the measure to which they seize the opportunity, their prestige both as teaching and research institutions should be enhanced.

GEOGRAPHICAL DISTRIBUTION OF EUROPEAN BIRDS

Atlas of European Birds

By Prof. K. H. Voous. Pp. 284 (419 maps and 355 gravure plates). (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1960.) 70s. net.

THIS splendidly produced volume fills a long-felt need in ornithology. A map is given showing the full breeding range of every species of bird that nests in Europe. For this purpose two basic maps have been used, one extending to the equator and the other covering the world, and so planned that one occupies half the space of the other, thus simplifying the arrangement. On each map the land is left uncoloured, the sea is shown in blue and the range of the bird is over-printed in red, which makes for extremely clear presentation. The author has used question-marks wherever there is doubt as to the range concerned.

The author's text is clear, concise and sound. He has in each case detailed the geographical range and habitat, and wherever these present problems of biological interest he has discussed them, so that the book is both a reliable summary of the known and a valuable guide to questions of zoo-geography and species-formation that would profitably repay further research. He has not discussed sub-specific variation except in a few cases where the allocation of species is difficult, but, while I think that it was fully justifiable to omit sub-specific names, I am sorry that he did not give a little more attention to the main trends of sub-specific variation. This is not, however, a serious omission. The author's treatment of the taxonomic limits of each species is very sound, and while it would be impossible to please all authorities, he has given his reasons where he differs from what may be found in other standard works. He has added short notes on food, nest-site and migration. Perhaps it is ungenerous to ask for more, but a second series of maps illustrating the range of each migratory species in winter is needed for proper evaluation of distributional problems, and such maps are not included.

The third section of the book is, in my view, irrelevant to the others. A black-and-white photograph is given of almost every species, providing a unique assemblage of fine photographs, even though many are already familiar from other bird-books. As a guide to identification, photographs can be misleading, particularly as there is no indication of the size of the bird. For example, in the double page featuring all the acrocephaline warblers, the smallest of all, to judge from the photographs, is the great reed warbler, which is in fact the largest of those shown. Anyway such photographs, being essentially bird portraits and not habitat pictures, are inappropriate to a bird atlas. There was, indeed, a strong case for two separate books, the first dealing with zoo-geography and the second with photographs, and omission of the latter from the atlas would, I imagine, have reduced its cost to less than half, and would have permitted printing on pages of half the present size, thus making it an even more valuable reference book than it is now. The photographs appeal to a different type of ornithologist and could have been issued separately with, perhaps, a brief description of each bird.

D. LACK

SEA BIRDS

Sea Birds

By Charles Vaucher. Translated by James Hogarth. Pp. 254 (255 photographs). (Edinburgh and London: Oliver and Boyd, Ltd., 1960.) 105s. net.

THIS is a sumptuous volume, beautifully produced, and its 255 photographs, 15 of which are in colour, are fine examples of the art of the camera. Charles Vaucher, their author, is to be congratulated on them. They include close-up bird portraits, snapshots of birds on the wing, some seascapes, among them an excellent picture of a four-mast sailing ship becalmed on a placid sea, and two or three shots of grey seals on the Farne Islands by way of contrast. Despite the seals, this is a bird book dealing with the birds to be found on or near the sea, particularly on the coasts of northern Europe, especially those of Britain and Scandinavia.

As indicated, this is primarily a picture book; but the literary matter is far from negligible or unimportant. The author amplifies the plates with chapters on the different species illustrated, their habits and habitats. He writes of what he has seen, with many interesting observations on bird conduct and behaviour, he gives us facts concerning distribution, breeding places, etc., and tells about his visits to many of the great seabird haunts in England, Scotland, Sweden, Finland and so on, his delight being the spectacular species that may be found on cliff, shore and island.

The author's style is concise but pleasant, and he has the gift of vivid description. We must not forget this is a translation from the French in which it was written and first published; however, it does not read as if it has lost anything in the process.

The latter part of the book is devoted to "Descriptive Summaries" in which the facts concerning each bird are set out concisely so that they may be seen at a glance.

Reverting to the pictures, which are all good, it is difficult to pick out one for special mention, but the photograph of an arctic tern on p. 189 is a remarkable study of a bird in flight, every detail, every feather, being depicted of the spread wings and spread tail.

A parent or other person wishing to give a boy or girl a present could not do better than choose this book, for it will surely fire youthful enthusiasm.

FRANCES PITT

CRYSTALLOGRAPHY CONDENSED

General Crystallography

A Brief Compendium. By W. F. de Jong, with the collaboration of J. Bouman. (Series of Books in Geology). Pp. ix+281. (San Francisco: W. H. Freeman and Company, 1959.) 38s.

ORIGINALLY published in Dutch in 1951, this work has now been enlarged and partially re-written for an English language edition. The primary object was to provide a review of the whole subject of crystallography; in the preface the author suggests that his book may also be used as a guide in private study, and by undergraduates as a summary of modern ideas on the subject. The book is in four parts, the first and longest (92 pages), on geometrical crystallography, being followed by sections on

structure theory and determination (43 pages), crystal chemistry (53 pages) and crystal physics (79 pages).

To review a whole science in a small space is a task calling for the most careful selection and presentation. The author has chosen to make his book reasonably encyclopædic, keeping down the length by a terse style of writing, by the use of numerous excellent diagrams, and by a multitude of references to more specialized works. The selection has, in fact, been a local, as against a regional, one. Considered as a compendium rather than a text-book and in view of its length, this is a successful book, remarkably complete and accurate. The brevity of the presentation has many drawbacks, of course; thus results are often stated without proper derivation, and the mathematical sections inevitably make dull reading. In the more descriptive chemical and physical sections the *hors d'œuvres* presentation certainly whets the appetite, but for the main course one is referred to other books. The section devoted to the explanation of crystal properties in terms of atoms is the most original and interesting one with a wide scope, including such topics as Frank-Read sources of dislocations, Raman radiation and transistors. Even the granitization theory gets a brief mention, one of the few reminders that this book is part of a geological series.

The proper balance for a work of this kind is a matter of opinion, but probably most English-speaking crystallographers will feel that the theoretical side here outweighs the experimental one, and that the geometrical section in particular is far too heavy for the rest.

A few detailed criticisms may be made. The author goes against well-established nomenclature in certain places. For example, he uses 'solid solution' for what would normally be called an interstitial structure, the usual solid solution becoming a 'substitutional structure'. Again, (*hkl*) is used in place of (*hkl*) for four-axis Miller-Bravais indices with no real justification. Whatever the reasons for such changes, it is a mistake to introduce them in a reference book.

For the professional crystallographer this book will have some value for reference, particularly for the geometric part, as this is otherwise mostly treated in German texts. As a guide to private work it would be hard going without advice on selection. Parts of the book will be valuable to the undergraduate for revision or summary, while others are too advanced.

M. G. BOWN

GEOLOGY IN THE UNITED STATES

Geological Survey Research 1960

Professional Paper 400, U.S. Geological Survey. Vol. A, Synopsis of Geologic Results. Pp. xii+136, 1 dollar. Vol. B, Short Papers in the Geological Sciences. Pp. viii+515. 4.25 dollars. (Washington, D.C.: Government Printing Office, 1960.)

FOR many years the United States Geological Survey has had a greater output of research in the Earth sciences than any other organization in the world. The immense mass of its publications, embracing the work of close on a thousand geologists, coupled with the inevitable delays in printing long detailed reports, has, however, resulted in some of

its work not being known as widely or as speedily as it deserves to be; and to provide a more prompt and succinct release of new information the Survey has now issued this summary of progress which, if found useful, will henceforth be published annually. The publication is in two quarto volumes. The first presents a narrative synopsis of the technical activities of the Geologic Division during the fiscal year ended June 30, 1960. The second comprises 232 papers, most of them less than 1,000 words in length, which are either announcements of new discoveries on problems of limited scope or reviews of the results of extensive investigations that have been in progress for some time.

In his preface Dr. T. B. Nolan, director of the U.S. Geological Survey, states that "This report is frankly an experiment". The experiment is a highly successful one, for all but the most parochial workers in the geological sciences will find in these columns contributions within their fields of interest. The short papers are concerned with economic geology (42 contributions), exploration and mapping techniques (20), geology applied to engineering and public health (11), regional geology mainly of the United States (101), palaeontology (6), geophysics (14), mineralogy, chemistry, and petrology (20), and analytical or petrographic methods (18). Notwithstanding the remarkable rapidity in publication a high editorial standard is maintained throughout; and Dr. V. E. McKelvey, who planned and directed the preparation of the volumes, is to be congratulated on the overall lucidity of presentation. Undoubtedly this review of progress will henceforth be one of the high-lights of the geological year; and by setting an example it should do much to improve and speed up the annual reports of other national surveys.

C. F. DAVIDSON

COAL SCIENCE: AN INDIAN VENTURE

Proceedings of the Symposium on the Nature of Coal

Held at the Central Fuel Research Institute, Jealgora, 7th-9th February, 1959. (Organized by the Central Fuel Research Institute in collaboration with the Institute of Fuel, Indian Section.) Pp. viii+321. (Jealgora: The Central Fuel Research Institute, undated.) n.p.

A REPORT of the symposium on "The Nature of Coal", held at the Central Fuel Research Institute, Jealgora, has already appeared in these pages (*Nature*, 183, 1438; 1959); now the proceedings have become available.

The volume is well produced and I have come across few typographical errors; all papers are written in English. As often with such collections, more than a year has elapsed between conference and publication of the proceedings; as a result, some sections, especially that on the rapidly developing subject of coal chemistry, no longer represent the latest views on all aspects considered.

The conference was divided into six sessions as follows: origin and systematics of coal; petrographic and X-ray studies on coal; ultra-fine structure of coal; coal constitution, physical methods; coal constitution, chemical methods; physico-chemical properties of coal.

The attendance from Western European countries, North America and Australia was unfortunately small, and most of the papers from these areas, for example those by H. Barking and C. Eymann, N. Berkowitz, J. D. Brooks, I. G. C. Dryden, R. A. Durie and S. Sternhell, C. Kröger and Dobmaier, and M. Samec, could not therefore receive adequate discussion. A paper from the Canadian Bureau of Mines and Technical Surveys was presented by one of the authors, B. N. Nandi. To judge from the printed discussion, similar difficulties limited the consideration given to papers from the U.S.S.R. and eastern Europe, of which there were nine distributed over the first five sessions, mainly in the first, and of those from Japan (three). Half the forty papers presented originated outside India.

The selection of papers with especial interest is invidious and must be to some extent personal to the reviewer. However, I would mention three: "Carbon-bound Methyl Groups and the Mechanism of Coalification", by Kaiser, Rao and Lahiri in particular; "Pyrolysis and its Relation to the Structural Parameters of Coal", by Mazumdar, Chakrabartty and Lahiri; and "Relation between Chemical Constitution and Pyrolysis of Coal", by Biswas, Sarkar, Kini, Das Gupta and Lahiri. Less personal perhaps is surprise at the widespread tendency to record chemical analyses to two places of decimals when only one is justified by the available analytical techniques. It is disappointing to find only eight pages of discussion on three hundred pages of papers presented. Despite the title of the symposium, the technology of the applications of coal is not unrepresented. The whole volume is of considerable interest both for reading and reference.

I. G. C. DRYDEN

PESTS AND THEIR CONTROL

Horticultural Pests

Detection and Control. By G. Fox Wilson. New edition, revised by Dr. P. Becker. (Agricultural and Horticultural Series.) Pp. xix+240+4 plates. (London: Crosby Lockwood and Son, Ltd., 1960.) 25s. net.

Chemical and Natural Control of Pests

By E. R. de Ong. Pp. viii+244. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1960.) 60s. net.

Ten Little Housemates

By Karl von Frisch. Pp. 146. (London and New York: Pergamon Press, 1960.) 17s. 6d. net.

THE late George Fox Wilson was a garden lover and economic entomologist with profound experience of the pest problems that beset the gardener, and the rare gift of being able to write clearly, accurately and interestingly for the layman. His book, "The Detection and Control of Garden Pests", was therefore well received by all. In agreeing to revise it, Dr. Paul Becker not only had to stand the test of comparison with his predecessor, but also to bring the book up to date with recent rapid developments. He has been outstandingly successful.

The book has a new title, but retains its original form and content. Additions have had to be made: many new chemicals have come into use, and perhaps as a result of their misuse we have been forcibly

reminded of the existence and importance of the natural enemies of insects. Thus Dr. Becker has rewritten the section on biological control and very sensibly continued to stress the importance of cultural and other practices that reduce the need to use insecticides.

There are more illustrations and the excellent quality of the paper used has made the most of them. The colour photographs, mostly provided by the Shell Photographic Unit, are exquisite.

Except for the few who correctly foresaw the problems that might arise, the dawn of the synthetic insecticide era seemed to be heralded by many economic entomologists as the beginning of the end of our insect competitors. Within a few years, however, it appeared likely that insecticides were creating as many problems as they solved, and we became only too familiar with such things as pest resurgence and resistance to insecticides. Such things were not really new, but in the excitement of new chemical discoveries they were often forgotten. Perhaps the most important by-product of this era was the stimulus it gave to ecological and other studies of pests, and to thoughts about the rational use of insecticides. That is, to try to put it briefly, how these undoubtedly valuable chemicals can best be used in combination with cultural and other practices to minimize pest damage without interfering with the benefits that may be derived from the activity of beneficial insects, or of inducing other undesirable side-effects. This approach is clearly reflected in Dr. Becker's book, and a great deal of fascinating work has been done along these lines in North America and in Europe.

If the title of Dr. E. R. de Ong's book leads the reader to expect a balanced account of recent work on rational pest control he will be disappointed. This book deals mainly with the control of pests (insects, diseases and weeds) of crops and livestock, of the household and of storage in the United States. There is little doubt that the recommended measures are sound, and that the quite well-arranged information will be of use to the American extension worker, but of much less value in the United Kingdom.

In "Ten Little Housemates" Prof. Karl von Frisch has written a series of essays that give the impression that he enjoyed writing them. If the purist is prepared to tolerate a work that makes no pretence of being a scientific treatise, no doubt he will be able to enjoy them too. It is written for the layman who takes an intelligent interest in what he sees around him, and for him this little book can be recommended.

F. H. JACOB

GROWING POINTS IN PLANTS

Gründzuge der Histogenese Höherer Pflanzen

Von Prof. Dr. Hermann von Guttenberg. 1: Die Angiospermen. (Handbuch der Pflanzenanatomie, Band VIII, Teil 3. Zweite, völlig neubearbeitete Auflage herausgegeben von Prof. Dr. W. Zimmermann und Prof. P. G. Ozenda.) Pp. viii+316. (Berlin-Nikolassee: Gebrüder Borntraeger, 1960.) 110 D.M.

THIS book is about the patterns of cells in the apical meristems of roots and shoots although its title may lead us to expect something else. It falls into three main parts, dealing with roots, shoots

and leaves, and there is a short section on a few anatomical aspects of differentiation. Prof. Guttenberg is well known for his work on root apices, and, for some people, the most useful part of the book will be the summary of his views on these, but the other two main sections are useful, painstaking accounts of developmental anatomy of the comparative kind. The book is profusely illustrated with modern line drawings and a few badly reproduced photographs.

It is marred by an almost total exclusion of any work which is not a simple consideration of cell patterns and by a dogmatic assertion of the author's views on these. He has not appreciated that merely putting some arrows on a diagram is not good evidence that cells behave in the way he says they do. Prof. Guttenberg does not like my interpretation of root meristems, and, to attack this, he ascribes to me views which I do not hold and does not try to explain the facts which, in spite of his protestations, are inconsistent with his own interpretation. Similarly, he has missed the significance of Thielke's important work on chimeras and of some American work on shoot apices. There are also some extraordinary gaps in some of the work presented and quite a lot of minor errors. There are, however, adequate indexes.

The book is likely to find a place in reference libraries partly because it is one of a reputable series of volumes on plant anatomy and partly because of its value as a comparative account of apical structure. Its price is likely to keep it out of personal libraries in Great Britain. Its old-fashioned approach is not likely to inspire a young biologist to study apices, and this is a pity to-day when there are so many opportunities for useful work on the behaviour of meristems. F. A. L. CLOWES

FLORA OF TROPICAL EAST AFRICA

Loganiaceae

By E. A. Bruce and J. Lewis. Edited by C. E. Hubbard and E. Milne-Redhead. Pp. 47. (London: Crown Agents for Overseas Governments and Administrations, 1960.) 4s.

THE "Flora of Tropical East Africa", of which the parts dealing with the families Loganiaceae by Mr. J. Lewis and the late Miss E. A. Bruce, Rosaceae by the late Mr. R. A. Graham, and Alismataceae and Butomaceae by Miss S. Carter have been published this year, covers the territories of Kenya, Uganda, Tanganyika and Zanzibar, an area of about 707,000 square miles in all. The Flora, which is being prepared under the editorship of Dr. C. E. Hubbard and Mr. E. Milne-Redhead, is being published family by family in separate parts with individual paging and pricing. So far 30 parts, including an introductory part and a glossary, have been published. Although the work is centred at Kew, much of it has been carried out by staff appointed by the Colonial Office for work on this Flora.

The Flora itself contains keys both to the genera and species, and also where necessary to sub-species and varieties; in addition, there are descriptions which are not intended to be exhaustive, but sufficient to indicate the main features of importance in identification of the entities keyed. References to the most important literature, particularly that of concern in East Africa, are also given, and re-

presentative specimens from the territories in which each species occurs are cited, usually only a limited selection of the total number seen. There are, in addition, brief notes on the habitat of each species in East Africa and its distribution both in East Africa and elsewhere. As a great deal of new taxonomic research has been involved, many specific names hitherto accounted distinct are here reduced to synonymy for the first time, and the lists of synonyms (primarily those relating to East Africa) will be found to contain much otherwise unpublished information. Each part of the Flora is illustrated with black-and-white figures so as to represent the habit of at least the majority of the genera described. There are also comparative figures bringing together for comparison diagnostically important organs of a series of species. As the total number of species in the area is probably in the neighbourhood of eleven thousand, it will be realized that the labour involved in working out this Flora will be both massive and lengthy.

The area covered by this Flora is, at least for Africa, unusually varied both in climate and altitude, including different sorts of vegetation ranging from the rain-forest, found here and there in Uganda and north-western Tanganyika and still more rarely and locally elsewhere, to the semi-desert scrub of the northern parts of Kenya, and the wonderful afro-alpine vegetation of the high mountains of East Africa. Perhaps the majority of the area is covered by the different aspects of the grassland, wooded grassland and woodland that clothe such huge tracts of tropical Africa. On this variety of vegetation, which often reflects differences in climate, there is superimposed a variety of different floristic elements: the rain-forest flora the species of which are mostly typical of the Congo and West Africa, the rich and remarkable flora, often containing numerous endemics, in the patches of forest scattered near the coast, the Somalian flora in northern Kenya, which though perhaps not rich in species, contains, however, many found nowhere else but in north-eastern Africa, the remarkable mountain flora so well represented in East Africa, and the generalized woodland and grassland flora so typical of much of east and south-tropical Africa may be taken as examples.

One of the interesting results coming from the taxonomic research involved in this Flora is that many species are being shown to occupy unexpectedly wide areas in tropical Africa, and to display ranges of variation which may frequently be far-reaching and complicated. What is now shown to be a single, perhaps polymorphic species may in the past have been known under several different names, each corresponding to a different part of its total geographical range. This has often given rise to false and misleading ideas about endemism and the size of genera. The patterns of variation take many different forms, and may have originated in various ways, perhaps through the intrinsic variability of certain species, or perhaps through the swamping of originally distinct and separate species which have come into contact with one another for some cause, giving rise to numerous hybrids destined to outnumber their parent species. The presence of such problems is obvious enough, but the evidence is usually insufficient for more than guessing at their cause.

J. P. M. BRENNAN

Nuclear Radiation Measurement

By J. Sharpe. (Nuclear Engineering Monographs.) Pp. vii+71. (London: Temple Press, Ltd., 1960.) 12s. 6d. net.

THIS book is one of a series of short monographs on nuclear engineering subjects intended for university and technical college students, research assistants and qualified technicians. With only sixty-six pages of text the author has concentrated on outlining the physical principles by which the various detectors operate, and there is little practical information on their design and construction. Each of the four main chapters has a useful list of references, and there is a short index.

The first main chapter, which occupies one-third of the book, discusses the way by which charged and uncharged particles and electro-magnetic radiations interact with matter. The various processes of energy absorption are mentioned, and some relevant data are presented in tabular form. Emphasis is placed on the scintillation phosphor as a detector, and the properties of different types of phosphor are examined in some detail.

The next chapter describes the operating mechanism of different types of detector, including a mention of such specialized devices as cloud- and bubble-chambers and photographic emulsions. Perhaps inevitably, the treatment of the more common gas-ionization detectors (ion chambers, proportional counters and Geiger-Müller counters) is somewhat incomplete; there is a short section on multiplier photo-cells. There follows a small section listing the ancillary equipment necessary for the working of the detectors, such as power supplies, amplifiers, scalars, etc., and then the last main chapter considers the types of detector best suited for a number of specific applications. Mention is made of α -particle assay using a zinc sulphide phosphor or a flow proportional-counter, and the absolute and relative measurement of β -particles.

The measurement of the energy of gamma radiation by scintillation counters is described, and the use of X-ray proportional counters for low-energy X-radiation is mentioned. Detectors employing the boron-10 (n, α) reaction for thermal neutron measurement are described, and some techniques for the detection of fast neutrons are noted.

The book is clearly written and produced, and fulfils its aim of introducing the very wide subject to technical students and research assistants.

W. R. LOOSEMORE

Anorganische Chemie

Band 1. Von István Náray-Szabo. Pp. 664. (Budapest: Verlag der Ungarischen Akademie der Wissenschaften (Akadémiai Kiado), 1959.) n.p.

PROF. SZABO'S book is planned to extend to three volumes. It begins with a good, concise account of atomic structure, radioactivity, and the theory of valency. The author believes that a book on inorganic chemistry of this size should confine itself to its subject and not branch off into disquisitions on physical chemistry or organic chemistry. The elements are dealt with systematically in the order of the Periodic Table, the compounds being in a systematic order. There are tables of physical properties, an arrangement which saves space and is useful for reference. In a few places the treatment requires revision, for example, in the description of non-existent substances such as FO. The translation

from Hungarian into German makes the book accessible to a large class of readers, and it deserves to be successful.

J. R. PARTINGTON

Chemical Instrumentation

A Systematic Approach to Instrumental Analysis. By Dr. Howard A. Strobel. (Addison-Wesley Series in Chemistry.) Pp. xviii+654. (Reading, Mass. and London: Addison-Wesley Publishing Company, 1960.) 74s.

THIS is a volume of 653 pages, printed legibly on excellent paper, and it presents, in small compass, an extensive store-house of information on the theoretical and practical aspects of most known fields of instrumental analysis. Its range of topics is so incredibly wide that, from the practical laboratory point of view, some useful detail has, of necessity, been omitted. Nevertheless, as a book for the undergraduate or honours degree student it has much to commend it.

The theoretical approaches are excellently described; the compilation of methods has been admirably done, and the many diagrammatic illustrations are clear and singularly helpful.

Most fields of spectroscopy are succinctly described: radioactive techniques, polarography, gas chromatography, polarimetry, electrometric methods, etc., all find their place in the various chapters. Scientific fundamentals are never ignored; there are two chapters on basic electronics, including transistor circuitry, and the information contained therein materially assists the student in the real understanding of the instrumental methods covered in the text. Another interesting chapter deals with "Errors of Measurement". The book concludes with a suggested series of detailed laboratory experiments which parallel in diversity the topics covered by the author.

It is not often that the student can purchase so much scientific information at such a modest price.

D. T. LEWIS

The Bridal Bed

By Joseph Braddock. Pp. 189+8 plates. (London: Robert Hale, Ltd., 1960.) 18s. net.

THIS book is really an anthology, culled from a great variety of authors, some reliable and some otherwise, concerning marriage ceremonies in many parts of the world.

The book is divided into six parts. In the first the choice of the marriage partner is described, while in the second courtship as seen in both civilized and primitive communities is described in some detail. From these preliminaries spring naturally accounts of the wedding itself; and finally some consideration is given to what various writers have said about consummation and customs relating to the various human relationships within the marriage state.

For those who wish to gain a general idea of what has been said about marriage customs in both Western and Oriental countries this anthology would provide an excellent introduction, although it would have been much improved had more trouble been taken to verify references and avoid relying on authors whose inaccuracy must surely have been apparent. The book is well printed and arranged, although it is not easy to understand why the bibliography is not arranged in correct alphabetical order.

E. J. DINGWALL

LOW-TEMPERATURE FORMS OF ICE AS STUDIED BY X-RAY DIFFRACTION

By L. G. DOWELL and A. P. RINFRET

Tonawanda Research Laboratory, Linde Company, Division of Union Carbide Corporation, New York

IN recent years a number of investigators have studied the low-temperature, low-pressure structures of ice, using such techniques as thermal analysis (Pryde and Jones¹), electron diffraction (Konig²), and X-ray diffraction (Barnes³). A comprehensive treatment of the literature is given by Blackman and Lisgarten⁴. General agreement exists that there are three possible phases of ice at low temperatures and pressures, namely, hexagonal or ice I, diamond cubic, and vitreous. There is, however, wide divergence of opinion as to the details of formation of these phases and to the conditions for their existence. We have determined the temperature-ranges in which the various phases exist and the rates of transformation from one phase to another. We have been able to produce vitreous ice only by condensing water vapour on a surface maintained below -160°C . This vitreous ice undergoes a partial and irreversible change to cubic ice at temperatures above -160°C ., the rate of transformation being strongly dependent on temperature. The mixed cubic-vitreous phase undergoes an irreversible transformation to hexagonal ice I at temperatures above -130°C ., the rate also being dependent on temperature.

The basic X-ray equipment consisted of a water-cooled diffraction unit (Norelco Type 12045), a copper target X-ray tube, a scaler-ratemeter (Norelco Electronic Circuit Panel, Type 12096), a linear amplifier (Norelco Main Amplifier Chassis, Type 42234) and pulse-height analyser (Atomic Model 510). The diffractometer was built in our own shops but closely resembled the Norelco Type 42266. It was equipped with a flow-type proportional counter using an argon-methane (90:10) gas mixture.

A low-temperature vacuum chamber attachment was constructed as a replacement for the regular sample holder. It consisted of a hollow copper tank (Fig. 1) containing a depression for the sample plate and was attached to a phenolic block which was in turn attached to the sample shaft. An O-ring provided a vacuum seal between the vacuum chamber

back-plate and the phenolic block. The back-plate carried Kovar seals for the thermocouple leads and also carried the refrigerant lines. The vacuum cover was sealed to the back-plate with an O-ring and contained slots covered with polystyrene sheets as the X-ray windows. The vacuum connexion was also in the cover. The copper-constantan thermocouple was cemented to the sample plate with silver paint and was located just outside the area irradiated by the X-ray beam. A vapour inlet tube was inserted into the vacuum cover, and its tip was located 1 in. above the centre of the sample plate. Finally, a 0.00035-in. nickel foil sheet was placed over the depression in the tank and served both as a thermal radiation shield and as an X-ray filter.

The vacuum system consisted of a rotary oil-sealed pump which maintained a vacuum estimated at about 5μ except during sample preparation. This pressure provided adequate thermal insulation yet did not cause noticeable sublimation of the sample except at temperatures above -30°C . The total heat leak was such that the rate of warming was about 3 deg. C. per min. at -160°C . and less than 2 deg. C. per min. at -90°C . when the refrigerant supply was discontinued.

Two refrigerant systems were used. For investigations near -190°C ., liquid nitrogen was forced through the refrigerant lines directly into the cold cell. The minimum temperature obtained was -192°C . For most of this work, however, the various temperatures were maintained by means of a stream of nitrogen gas which first passed through a copper coil immersed in a Dewar flask of liquid nitrogen before moving into the cold cell. By controlling the rate of flow of the gaseous nitrogen, any temperature down to -175°C . could be maintained as long as needed.

Ice Structures

Hexagonal phase. Much has been published concerning the structure of ordinary hexagonal ice (usually called ice I), and the reader is referred to Owston⁵ for an excellent review of this literature. We will discuss the simple Barnes model of ice which shows only the oxygen arrangement in the lattice, since the hydrogen atoms contribute so little to the X-ray diffraction pattern.

One may conveniently consider the hexagonal model as being built up of layers of oxygen atoms, each layer consisting of a network of open puckered hexagonal rings. Each additional layer is a mirror image of the preceding layer, so that the stacking is of the $A \cdot B \cdot A \cdot B \cdot \dots$ sequence. It can be shown that this leads to the tetrahedral arrangement of atoms of oxygen known to exist in ice I. The c_0 parameter is twice the layer spacing and was found to be $7.338 \pm 0.004 \text{ \AA}$. at -175°C ., while the a_0 parameter was $4.498 \pm 0.002 \text{ \AA}$. There are four

molecules per unit cell, leading to a computed density of 0.924 gm./c.c. A typical X-ray diffraction pattern of this phase is shown in Fig. 2, and Table 1 shows the d values and relative intensities of all lines observed up to an angle of 56° (2θ). The lines are quite sharp, indicating no line broadening due to small particle size. The variation of intensity ratios from experiment to experiment indicates either the presence of large particles or of preferred orientation of somewhat smaller particles. The relative intensities listed in Table 1 are the averages of several typical patterns of this phase.

Table 1. X-RAY DIFFRACTION DATA FOR HEXAGONAL ICE AT -175°C .

hkl	2θ (deg.)	d (Å.)	I/I_0
100	22.82	3.897	100
002	24.26	3.669	75
101	25.89	3.441	53

Diamond cubic phase. König³ was probably the first to recognize and deduce the structure of cubic ice. Shallcross⁴ and Carpenter⁵ confirmed the identity of this structure, describing the conditions for its formation as well as its properties. The oxygen atoms are located in a diamond cubic lattice, but the structure may also be considered as being built up in layers of oxygen, each layer identical with that of the hexagonal phase. However, each successive layer is shifted one-half the diameter of the hexagonal ring, leading to the $A \cdot B \cdot C \cdot A \cdot B \cdot C \cdot \dots$ stacking sequence typical of the diamond cubic system.

We have found the cubic parameter to be $a_0 = 6.358 \pm 0.004$ Å. at -185°C , leading to a computed density of 0.923 gm./c.c. This density is identical with that of the hexagonal phase within experimental error. The similarity of the structures of the two phases is more easily seen by deducing the pseudohexagonal cell of the cubic phase and comparing it with the hexagonal phase (Table 2). It will be noticed that the a_0 parameters are the same, but the c_0 parameter of the pseudohexagonal cell is 50 per cent greater, leading to the same layer spacing for both phases.

Table 2. CRYSTAL PARAMETERS FOR HEXAGONAL AND CUBIC ICE

	Hexagonal	Cubic	
		Diamond cubic cell	Pseudohexagonal cell
a_0	4.498 Å.	6.358 Å	4.495 Å.
c_0	7.338 Å.	—	11.012 Å.
c_0/a_0	1.631	—	2.450
Layer spacing	3.669 Å.	—	3.671 Å.
Density	0.924 gm./cm. ³	0.923 gm./cm. ³	0.923 gm./cm. ³

A typical X-ray diffraction pattern of the cubic phase is shown in Fig. 3, and Table 3 lists the d values and intensities of all lines appearing up to 56° (2θ). The small peak appearing to the left of the (111) peak is partly due to a trace of hexagonal ice and partly to the maximum of the residual vitreous ice. The intensity ratios are quite reproducible and the lines show considerable broadening. Application of the Scherrer law gives an average particle size of about 400 Å. This same result is obtained regardless of the rate or temperature of transformation from the vitreous phase.

Fig. 3. X-ray diffraction pattern of diamond-cubic ice in the presence of vitreous ice

It should be pointed out that we have never observed the cubic phase in a pure state, but always with what has been considered as a modification of the original vitreous phase. This aspect of the problem is examined in the following section.

Vitreous phase. Fig. 4 shows a typical X-ray diffraction pattern of vitreous ice. It is characterized by two intensity maxima, one at 24° (2θ) corresponding to a Bragg spacing of 3.71 Å. and having a half-width of 5.0° , and the second at 42° (2θ) corresponding to 2.15 Å. Dorsey⁷ has compiled a list of X-ray diffraction patterns of liquid water reported by a number of investigators. These data indicate periodicities in the structure having values of 3.20 Å, 2.11 Å. and 1.35 Å. Although our observed value of 2.15 Å. and the reported value of 2.11 Å. are in

Table 3. X-RAY DIFFRACTION DATA FOR CUBIC ICE AT -185°C .

hkl	2θ (deg.)	d (Å.)	I/I_0
111	24.25	3.870	100
220	40.11	2.248	40
311	47.43	1.917	15

Fig. 4. X-ray diffraction pattern of vitreous ice

agreement, the 3.71 Å. observed value is unique. It is therefore evident that the structure of vitreous ice is different from that of water at ordinary temperatures. Further discussion of the structure of this phase is found in the final section of this article.

The portion of the original vitreous ice which remains after the cubic transformation is complete has also been altered. If the shape of the vitreous diffraction curve near 24° (20) is observed during the transformation to the cubic phase, it is found that the centre of the curve remains virtually unchanged, whereas the intensity gradually diminishes on the high-angle side and more abruptly on the low-angle side. At the same time, the relatively sharp cubic (111) line appears on the crest of the vitreous maximum. When an estimated 30 per cent of the vitreous ice has been transformed to the cubic phase, the conversion ceases regardless of the time or temperature involved. In addition, this same pattern is observed when the original condensation is carried out at temperatures sufficiently high to form the cubic phase directly.

Production of Vitreous Ice

Several attempts were made to produce vitreous ice from liquid water, but none was successful. They included spraying water on a substrate held at -190° C., and plunging films of water on metal foils into liquid nitrogen. Only normal hexagonal ice resulted, as might be expected from Luyet's⁸ prediction that a cooling-rate of 20,000 deg. C. per sec. would be required to vitrify liquid water.

In another method, atmospheric moisture was collected on the refrigerated sample plate. Small amounts of vitreous ice were obtained; but, as the deposit formed, the surface temperature rose due to the insulating effect of the ice layer and the crystalline forms of ice appeared, as did solid carbon dioxide.

The condensation of pure water vapour is the most reliable and practical method of producing vitreous ice. Although the direct condensation of vapour from a liquid or solid source has been used by most investigators, we have found that greater control can be exercised by using a stream of wet gas. We caused a small stream of nitrogen gas to pass through a spiral gas-washing bottle containing distilled water and then through a needle valve into the vapour inlet tube built into the vacuum cover of the low-temperature cell. The wet gas impinged on the centre of the cold sample plate, where the water vapour was condensed and the nitrogen was continuously pumped off. The thickness of the ice film

was computed by measuring the decrease in intensity of the diffraction pattern of the silver sample plate. At a rate of flow of 75 c.c. per min. of wet nitrogen, a layer of ice 60μ thick was deposited in 30 min.

No attempt was made to determine accurately the conditions for the formation of the various phases from the vapour state. However, we found that vitreous ice could be formed at any temperature below -160° C., while various amounts of cubic ice appeared if condensation occurred at higher temperatures. Above -120° C. a very highly oriented film of hexagonal ice formed. We also found 60μ to be the maximum thickness of vitreous ice obtainable. This was also probably due to the high surface temperature acquired as the deposit thickened.

Most of the work reported here was carried out using a polycrystalline silver plate for the substrate. To test the substrate effect several trial experiments were made using a glass plate, but in no part of the entire procedure was any difference noted. It is concluded that our results are free of any substrate effects.

Phase Transformations

Vitreous to cubic. This irreversible phase change was observed to be strongly dependent on temperature and took place in the temperature range -130° to -160° C. At higher temperatures, the conversion is very rapid and no measurements of rate were made. The rate of transformation was measured by setting the X-ray diffractometer at the correct angle for the cubic (111) line and observing the increase in intensity as a function of time at various temperatures. The transformation appears to proceed linearly with time, until it nears completion, when it suddenly slows. The conversion times were obtained by extrapolating the main part of the time-intensity curves to the maximum intensities when equilibrium was reached. It should be noted that this occurs when about 30 per cent of the original ice has been converted, as estimated from the area under the vitreous curve and the peak heights of the crystalline phases. For the lower temperatures the scaler and timer were used periodically to determine the increase in counting-rate with increasing time. The temperature was then raised to -120° C. for a short time to ensure the maximum conversion, the counting rate was measured, and the transformation time was computed. Equation 1 relates conversion time and sample temperature in the range of -135° C. to -160° C.:

$$t = 2.04 \times 10^{12} \times \exp(-0.465T) \quad (1)$$

where t is the time in minutes for the conversion and T is the absolute temperature in degrees Kelvin. A graph of observed values is shown in Fig. 5. The transformation occurs rapidly above -135° C., and if the temperature of a specimen of vitreous ice is raised at a rate of 5 deg. per min., the conversion appears to take place suddenly near -130° C.

A single determination of rate was carried out at -160° C., but since the 12-hr. observation period was a small fraction of the computed transformation time of 205 days, we do not consider that observations at this temperature are reliable. One approach to this problem is to store a specimen for weeks at -160° C. and lower, and to examine it periodically by X-ray diffraction methods to determine whether our equation is valid for lower temperatures.

Fig. 5. The time necessary for the conversion of vitreous to cubic ice

Cubic to hexagonal. A further increase in temperature above -130°C. allows transformation to the hexagonal phase. Although it is certain that the residual vitreous ice becomes converted to hexagonal ice, the evidence that the cubic phase is also converted is indirect. All three diamond cubic lines exactly coincide with hexagonal lines, and the large particle size and possible orientation effects of the hexagonal phase make the analysis of intensity ratios a poor guide to the presence of the cubic phase. However, the sharpness of the hexagonal lines and the lack of broadness near the base of the lines show that the cubic ice, if present, has appreciably increased in particle size. We conclude that probably both the vitreous and the cubic forms are converted to the hexagonal phase, and we will call it the cubic-hexagonal transformation.

The rate of this transformation is also dependent on temperature, although much less sensitive in this respect than is the vitreous-cubic change. The rate was measured with the same procedure described earlier, except that the diffractometer was set at the angle for the (100) line of hexagonal ice. Equation 2 relates time of conversion and sample temperature in the range of -65° to -120°C. :

$$t = 2.58 \times 10^{13} \times \exp(-0.126T) \quad (2)$$

with t in minutes and T in degrees Kelvin. The observed values are shown in Fig. 6. This transformation occurs rapidly above -70°C. , and if the temperature of a specimen of vitreous and cubic ice is raised at a rate of $5^{\circ}\text{C. per min.}$ the conversion takes place rather quickly near -60°C.

A single determination of rate was carried out at -120°C. , but here also the time of observation was too short for us to obtain reliable results.

Discussion and Conclusion

The results presented require consideration of alternatives with respect to the actual structure of the vitreous phase. Of two possible interpretations of the observed diffraction pattern, one is that the 'vitreous' ice obtained by our procedure is composed of small particles of crystalline ice, so small that the

diffraction maxima are greatly broadened. Supporting this view is the fact that the $3.71\text{ \AA.}$ spacing is very close to the $3.67\text{ \AA.}$ value of the (111) line of cubic ice. Further, the $2.15\text{ \AA.}$ value is between those of the (220) and (311) lines of cubic ice, and could be due to the overlapping of these two lines. However, application of the Scherrer formula to the $3.71\text{ \AA.}$ peak gives a particle size of about $20\text{ \AA.}$, or about 3 unit cells in length. Since ordering is even less in the other directions and since the very essence of the crystalline state is the regular repetition of the unit cell, we consider it without significance to refer to this as a microcrystalline phase.

The second interpretation of this type of pattern is that 'vitreous' ice really has a typical vitreous or random network type of structure. In agreement with this theory are the following facts:

(1) No sharp conversion temperature from the vitreous phase was observed. This is consistent with the slow development of a crystalline lattice from a disordered array of molecules as the temperature is raised.

(2) Below -160°C. , substrate temperature and the rate of deposition of vapour produced no change in the X-ray diffraction pattern. Since crystal size is directly related to temperature, changes in the sharpness of the maxima could reasonably be expected between -190° and -160°C. if a microcrystalline structure were characteristic of vitreous ice.

(3) During the vitreous-cubic transformation (-160° to -130°C.) the intensity of the cubic peaks changed but their half-widths remained unaltered. This supports the interpretation of phase change (to a structure of constant particle diameter) rather than crystal growth.

(4) An exotherm near -130°C. was reported by Pryde and Jones¹. This observation would be expected if associated with a change in order, but would not be expected if associated with the growth of larger crystals at the expense of their smaller neighbours.

The foregoing observations predict that if a sample of vitreous ice is rapidly warmed, for example, $5^{\circ}\text{C. per min.}$, the vitreous-cubic transformation should

Fig. 6. The time necessary for the conversion of cubic to hexagonal ice

appear suddenly at about -130°C . In a number of such experiments we have observed a sudden increase in the intensity of the cubic (111) line in the range -126° to -130°C ., depending on the rate of increase of temperature. There can be little doubt that the exotherm reported by Pryde and Jones is due to this particular transformation and not to the vitreous-hexagonal one they have assumed. That we have observed only a partial transformation to the cubic structure is in agreement with their observation of a smaller amount of heat evolution during the phase transition than was expected on theoretical grounds.

If the fraction of the original vitreous ice that did not become converted to cubic ice is in fact vitreous, a second exotherm should be observed when it is converted to hexagonal ice. It is assumed that because of the structural similarity between the two crystalline phases very little heat will be evolved if or when the portion having the cubic structure is converted to the hexagonal. On the basis of the results presented for the cubic-hexagonal transformation, if the temperature is raised at about 5 deg. C. per min. through the -90° to -50°C . range, the second exotherm should appear at about -60°C . Pryde and Jones, however, state that no thermal change (other than that at -129°C .) occurred until the temperature reached 0°C . They did not include in their report the rate of warming of the specimen; but if, through the range -90° to -50°C ., it was not greater than that near -130°C ., it is likely that the exotherm would not have been observed. This is due to the relatively slow rate of crystallization to the hexagonal phase, a change which is far less sensitive to temperature than the vitreous-cubic transition. Slow crystallization would occur over a wide temperature-range making it difficult to observe an exotherm. To define more clearly the structure of

the vitreous state, precise thermal measurements should be carried out on samples shown by X-ray diffraction techniques to be in that state.

We conclude that in vitreous ice domains exist in which there is a tendency toward the same layer structure present in the crystalline phases, although with random distribution of molecules within the layers. Those domains having very nearly the same layer spacing as the crystalline phases are apparently quite stable, but those having greater disorder are unstable. At temperatures above -160°C ., crystallization to the cubic phase begins spontaneously at a few sites in the unstable zones, and the crystallites at each site quickly grow to about 400 Å., where further growth is hindered by the more stable zones. Further crystallization takes place at new sites in the unstable domains, the process continuing until all such areas have crystallized. This state is now stable at all temperatures below -130°C .

Above -130°C . both the cubic and the remaining vitreous ice begin to show conversion to the stable hexagonal phase, the individual crystallites growing to moderate size, probably near 10μ . In view of the abundant evidence showing that ice crystals can grow in size at temperatures many degrees below the freezing point, it is reasonable to suppose that the ultimate size of the crystallites will depend on the highest temperature to which the sample is exposed for a given time.

THE COLE LIBRARY OF ZOOLOGY AND EARLY MEDICINE, UNIVERSITY OF READING

IT has often been stated that the scientist is lacking in literary and artistic merit, yet this is far from the truth. Its complete falsity is demonstrated by the example of the renowned biologist, artist and historian of the evolution of biological knowledge and thought, the late Prof. F. J. Cole, who died in 1959 at the age of eighty-six. Whatever he did he made as perfect as possible, and his achievements in research, in the Department of Zoology which he founded at the University of Reading, the Museum which he built up, and the Library which he collected in his home, all testify to his greatness as a man of learning. When he retired from the professorship of zoology in 1939, the Council of the University resolved that the museum should be known as the Cole Museum (*Nature*, **177**, 555; 1956). This article deals with his library, henceforth to be known as the Cole Library.

Prof. Cole was a confirmed bibliophile. He collected books from his school-days onwards, throughout his long life. At first he bought the great monographs of biology, then turned more and more to the earlier works, so that at the end of his life he had built up a library of about eight thousand volumes, illustrating the history of early medicine and zoology from the

fifteenth century to the present day. In 1932 he had a house built on the Chilterns, literally around the bookcases, and after his retirement from the professorship of zoology in the University of Reading in 1939, he compiled author, title and subject catalogues, before writing his major historical work, "A History of Comparative Anatomy from Aristotle to the Eighteenth Century" (ref. 1).

This Library, the most exhaustive one of its kind in private hands in the country, has recently been acquired by the University of Reading. For the present the books will remain in the late Prof. Cole's house, where they will be available to scholars as heretofore; but when the new University Library building, to be erected in Whiteknights Park, is completed, they will be transferred to a room set apart for the books and the catalogues, as the Cole Library, a fitting complement to the Department of Zoology and the Cole Museum at the University of Reading.

The two earliest books in the library are incunabula. Pliny's "Natural History" ("Caii Plinii Secundi Naturalis Historiae Libri Tricesimiseptimi") was printed in Venice in 1472. Although rebound in

vellum, it is in perfect condition, and has thirty-five coloured illuminated capitals and one full-page illumination. Aristotle's "De Historia Animalium, De Partibus Animalium, De Generatione Animalium" (Venice, 1476) is the first edition of the Latin translation by Theodorus Gaza. That doodling was an ancient habit is evident from the contemporary patterns made in the margins by one Angelus Calydonius, who signed his name on p. 110, September 17, 1491.

It is noteworthy that nearly all the authors of biological books in the sixteenth and seventeenth centuries were medical men. Their works, for reasons that may be inferred, were frequently dedicated to dignitaries of the Church—cardinals and popes. Their subject was primarily the human body, though with references, not always acknowledged, to the bodies of animals. A beautiful copy of Galen's works in six volumes ("Omnia Quae Extant Opera ex Secunda Juntarum Editione") is in the Library. It was printed at Venice in 1550. But Galen's day was passing, and the professor no longer would read chapters from his works to his students. Independent accounts of the human body, based on dissection, were appearing. The first of these, and the most valuable book in the library, is "De Humani Corporis Fabrica" by Andreas Vesalius, first edition, printed at Basle in 1543. The second edition, 1555, is in its original tooled leather binding, with metal clasps, by Johannes Mechler, 1557. Prof. Cole never tired of showing these two magnificent folios to his visitors.

A valuable French book of the period is Estienne's "La Dissection des Parties du Corps Humain" (Paris, 1546).

Its beautiful binding is in red morocco, tooled gold. Thomas Vicary's "The English Man's Treasure, with the true Anatomie of Man's Bodie" (Black Letter, London, 1596) is a transcript of a fourteenth-century manuscript, and is therefore pre-Vesalian. Only two other copies of this edition were known to Prof. Cole—one in the Bodleian and the other in the Surgeon-General's Library in Washington. The first Englishman to make a systematic study of natural history was the physician Edward Wotton, who graduated, as Harvey did, at Padua. His book "De differentiis Animalium" (Lutetiae Parisiorum, 1552) is a fine copy bound in limp vellum.

The chair of anatomy at Padua was filled during the sixteenth and seventeenth centuries by Vesalius, Columbus, Fallopius, Fabricius, Casserius, Spigelius

and Veslingius. Vesalius has already been mentioned, and works by Columbus, Fabricius, Casserius and Veslingius are represented. Of the three works of Fabricius (Harvey's teacher) the most important is "Tractatus Quatuor" (Francofurti, 1624) which contains the section "De Venarum Ostioliis", and describes, without understanding of their function, the valves of the veins. The beautiful publications of Casserius, the pupil and understudy of Fabricius, include a fine copy, with portrait, of his "De Vocis Auditusque Organis Historia Anatomica", bound up with "De Auris Auditus Organi Historia Anatomica" (Ferrariae, 1601, 1600) and by his "Pentaestheseion, hoc est De Quinque Sensibus Liber" (Venetiis, 1609). Both works describe the sense organs of animals as

well as those of the human subject.

The study of aquatic animals interested physicians at this period. Pierre Belon, called by Casey Wood "the founder of modern ichthyology", published "L'Histoire Naturelle des Estranges Poissons Marins, avec la Vraie Peinture et Description du Dauphin" (Paris, 1551). This, the first edition, is very rare. But the finest early work on fishes is Salviani's "Aquatilium Animalium Historiae" (Romae, 1554), famous for its eighty-one full-page copper-plate engravings of fishes and marine creatures by Nicolas Béatrizet. Rondelet's "Libri de Piscibus Marinis" (Lugduni, 1554-55), with its cruder but more numerous woodcuts of all kinds of marine creatures, is in its original tooled leather binding, with metal clasps.

An interesting, rare and beautiful volume, the provenance of which was described by Prof. Cole in his "Obiter Dicta Bibliographica", is Carlo Ruini's "Dell'Anotomia

et dell'Infirmita del Cavallo" (Bologna, 1598). This is the first complete work on the anatomy of an animal, and was plagiarized by Snape and others.

We come now to the seventeenth century, "the most constructive and significant period in the history of modern biology". The whole animal kingdom is reviewed in the eleven publications of Aldrovandus, ranging from 1613 to 1668. Four books by Severino include a fine copy of his "Zootomia Democritaeae", with portrait (Noribergae, 1645). Six works of Walter Charleton, with a copy of the first edition of his "Onomastikon Zoicon" (Londini, 1668). Eight works by Redi, who in his "Esperienze intorno alla Generatione degl' Insetti" (Firenze, 1668), "successfully attacked by experiment the universal belief in

Giulio Casserio (1552-1616)

spontaneous generation". Nine works by Jan Swammerdam, whose "Ephemeris Vita of afbeeldingh van's Menschen Leven" (t'Amsterdam, 1675), is the first edition of a superb monograph on the may-fly. Two volumes of Samuel Collins's "Systeme of Anatomy, treating of the Body of Man, Beasts, Birds, Fish, Insects and Plants" (London, 1685), the first treatise on comparative anatomy by an Englishman, and with an extremely fine engraved portrait by Faithorne. Edward Tyson's "Orang-outang [that is, chimpanzee], sive Homo sylvestris, or the Anatomy of a Pygmie compared with that of a Monkey, an Ape and a Man" (first edition, London, 1699) is signed "The Author's gift, June 9, 1699".

The seventeenth century was the century of William Harvey. Prof. Cole did not possess a first edition of Harvey's "De Motu Cordis et Sanguinis Circulatione"; but he had copies of all the facsimile productions and translations down to Dr. Franklin's translation of 1958. In this work Harvey put the last stone on an edifice, the foundations of which had been built by many other workers, but in his work on generation in animals ("Exercitationes de Generatione Animalium"; first edition, Londini, 1651) he was a pioneer, and the book was described by Prof. Cole as the "work of a sadly puzzled human being". The Elzevir edition (Amstelodami, 1651) was T. H. Huxley's copy.

A remarkable feature of the seventeenth century was the foundation of learned societies in the great capitals of Europe, and the participation of groups of investigators in research. Though the series of the *Philosophical Transactions of the Royal Society* is not complete, the earliest and rarest volumes and also long runs are in the library. The fifteen volumes of the German "Academia Naturae Curiosorum" (Frankfurt und Leipzig, 1670-90) is a fine series, bound in the original vellum. Of the Danish publication, "Acta Medica et Philosophica Hafniensia", associated with Thomas Bartholin, 1671-79 (all issued), published 1673-80, only two other complete copies were known to Prof. Cole. Vol. 1 bears the signature of Clopton Havers, M.D. The Amsterdam Society was short-lived, and Prof. Cole was unable to purchase a copy of its *Proceedings*, so he had a facsimile edition of a hundred copies of "Observationes anatomicae selectiores Collegii privati Amstelodamensis" (Amstelodami, 1667-73), printed in the Typography Department of the University of Reading in 1938. Of the "Académie des Sciences" in Paris, there are the two volumes, large folio, of C. Perrault's "Mémoire pour servir à l'histoire naturelle des Animaux" (Paris, 1671 and 1676), and a magnificent copy of the 1676 volume, handsomely bound in red morocco, with the royal fleur-de-lis tooled in gold, and showing on the title-page Louis XIV and his minister Colbert attending a meeting of the Academy in the Royal Library at Versailles in 1671. The Italian Society, Accademia del Cimento, is in Richard Waller's English translation, entitled "Essays of Natural Experiments made in the Academie del Cimento" (London, 1684).

Returning to the Royal Society, there are the works of many of the original Fellows. Robert Boyle's six works include the complete works in five volumes printed in 1744; this set was formerly the property of the Boyle family, and bears the bookplate of the Earl of Cork and Orrery. Thomas Willis is represented by six works, including the first edition of "Cerebri Anatome", 1664, Robert Hooke by seven works, including the first and second editions of the "Micro-

graphica" (1665 and 1667 respectively), Nehemiah Grew by six works, including his "Anatomy of Vegetables Begun" (1672), "The Anatomy of Plants" (1682) and "The Comparative Anatomy of Stomachs and Guts Begun" (1681) and Marcello Malpighi by seven works, a most valuable and complete set, including the "Opera Omnia", which Prof. Cole made perfect by buying three copies and binding the three volumes in one, with the portrait and the life (Londini, 1687, 1686 and 1697). There are fine copies of "Dissertatio epistolica de Bombyce" (first edition, Londini, 1669) and "Dissertatio epistolica de Formatione Pulli in Ovo" (first edition, Londini, 1673). Among the eight works of Antoni van Leeuwenhoek, the Dutch draper who, working in isolation, had to trust to his own observation and judgment, are the Dutch edition of his works in four volumes (Leyden and Delft, 1684-1718), the Latin edition (Lugd. Bat., 1722), the select works in four volumes (1798-99 and 1800-07) and the current "Collected Letters of Antoni van Leeuwenhoek, vols. 1-5 (all published to date) (1939-57).

The eighteenth century was a period of great activity by numerous major and minor investigators in all branches of biology, particularly in the attempt to understand the functions of the organs of animals. So physiology went side by side with anatomy. The microscope, too, was coming into use, thus enabling the minutest parts of animals to be examined. Museums were founded, and great skill was shown in preserving, injecting and otherwise exhibiting whole animals or their parts. There was a great accumulation of factual knowledge in preparation for the Darwinian era in the following century. Only a few of the outstanding works can be mentioned, chosen to illustrate the diversity of treatment and subject. "Oeuvres anatomiques de M. Duverney" (two volumes, Paris, 1761) contains reprints of his beautiful and detailed studies on the sinuses of the dura mater, on the structure, function and diseases of the ear, and the first accurate account of the solar plexus. Spallanzani's seventeen works include his "Essay on Animal Reproductions", translated from the Italian of 1768 (London, 1769), the forerunner to his conclusive experiments on the origin of life, described in his "Opuscula di Fisica Animale et Vegetabile" (first edition, two volumes, Modena, 1776). Comprehensive faunistic works were beginning to appear, one of the earliest being O. F. Müller's "Zoologica Danica" (third edition, Havniae, 1788-1806) with many illustrations of marine animals. It was published posthumously. The learned Swiss Albrecht von Haller, physician, physiologist, bibliographer and poet, has twenty-one entries in the catalogue. As a bibliographer his work is indispensable to a historian of biology, and the library contains his "Bibliotheca Botanica" (2 vols., Tiguri, 1771-72), "Bibliotheca Chirurgica" (2 vols., Bernae, 1774-75), "Bibliotheca Anatomica" (2 vols., Tiguri, 1774-77) and "Bibliotheca Medicinæ Practicae" (4 vols., Bernae and Basiliae, 1776-88). It is said that Haller's library contained 13,500 volumes and that he wrote more than five hundred scientific papers. Prof. Cole was a great admirer of John Hunter, and his famous Museum, on which he planned his own Museum at the University of Reading. Hunter was not a diligent writer, and there are only six books of his in the Library; but there are nearly forty entries of references to him and his work. A complete publication of John Hunter's works in four volumes was published in London, 1835-37. John's elegant brother

William was a renowned lecturer. Prof. Cole had two sets of manuscript notes of his lectures (c. 1770), one of 280 pages, testifying to the appreciation and diligence of two of his students.

The nineteenth and twentieth centuries have produced a voluminous literature in every branch of zoology. The Library contains beautiful monographs in many languages. It is also rich in biographical and bibliographical works. Among the latter may be mentioned the Index Catalogue of the Library of the Surgeon General's Office, U.S. Army, Washington, which Prof. Cole used constantly. The first, second and third series, in 16, 21 and 10 volumes respectively, are present. Of the modern transcriptions and translations there are the works of Leonardo da Vinci, namely, "Codice sul volo degli Ucelli" (first edition, Rouveyre, Parigi, 1893), with the perfect facsimile of the original, "Dell'Anatomia, Fogli A"

(Parigi, 1898), "I Manoscritti di Leonardo da Vinci, della Reale Bibliotheca di Windsor. Dell'Anatomia, Fogli B" (Torino, 1901), half the series (13 volumes) of the "Feuillets inédits" (Paris, 1901) and "Quaderni d'Anatomia", six volumes (Christiania, 1911-16), a truly noble collection, as most of these are limited editions.

The above selection can give only a meagre idea of the richness and scope of this wonderful library. Prof. Cole's wishes were that it should not be dispersed, but should be available *in toto*, as it has been in the past, to scholars in the history of biological thought. This happy outcome has, we believe, been achieved by its acquisition by the University of Reading.

OBITUARIES

Prof. W. N. Thomas, C.B.E.

PROF. W. N. THOMAS, professor of engineering in University College, Cardiff, during 1928-50, died on November 24.

His initial engineering training was as pupil and assistant of the Borough Engineer at Crewe.

During 1910-15 he lectured at the Universities of Nottingham and Birmingham. He then saw war service with the Royal Engineers in France and Flanders. He returned to university life at Birmingham and afterwards at Oxford, where he was chief assistant to Prof. Jenkin for five years and received the degrees of M.A. and D.Phil. He left Oxford to become principal assistant at the Building Research Station at Garston, and three years later, in 1928, he was appointed professor of engineering at Cardiff, a post in which he remained until his retirement in 1950.

His time at Cardiff was broken by war service. In 1939 he became scientific adviser to the Ministry of Home Security, and an expert on the effects of bombs on structures. He visited Moscow in 1941 and led a team of specialists to Japan in 1945 to report on the atom-bomb damage at Nagasaki and Hiroshima. In 1946 his war work was recognized by the award of the American Medal of Freedom and he was made C.B.E.

On retirement from the University of Wales, Norman Thomas became president of the South Wales Institute of Engineers, and presided over the difficult negotiations which led to its amalgamation with the South Western Society of Mining Engineers. He continued his association with the Home Office and became chief scientific adviser for Wales on civil defence. He relinquished this appointment only a year ago. He was also active in the affairs of the Institution of Civil Engineers and made a number of journeys abroad on its behalf.

His academic interests were well spread. Norman Thomas was an authority on the effect of frost on materials, and he published many papers on the mechanical properties of materials. He was author of a well-known text-book on surveying, and completed a further revision within a year of his death. He also wrote a book on bridges and was interested in military bridging. While at Cardiff he succeeded

in having constructed an addition to his somewhat modest laboratories, and he lived long enough to take part in a token demolition of the wooden walls which were his academic inheritance; and to see the demolition proper commence. His colleagues greatly regret that he did not survive a few more years to see the splendid new laboratories which will replace them.

In personal characteristics, Norman Thomas was modest and retiring, but his quietly expressed opinions were well received by his colleagues, and he had an unusual capacity for inspiring other people's affection.

C. GURNEY

Dr. Pierre A. Chappuis

THE Swiss zoologist Dr. P. A. Chappuis, who died at Zurich on July 9, 1960, was for many years assistant director of the Institut de Spéologie at Cluj, Rumania, where he also acted as Swiss Consul. At the time of his death he was attached to the Centre National de la Recherche Scientifique as director of research and assistant director of the Laboratoire Souterrain de Moulis (Ariège), France.

He was born on September 5, 1891, at Saint-Cloud, Seine-et-Oise, France, where his father was assistant director of the International Bureau of Weights and Measures. Educated in Switzerland, he obtained his doctorate at the University of Basle in 1920; his thesis on the fauna of the subterranean waters in the neighbourhood of Basle was prepared under Prof. F. Zschokke. The following year he joined the staff of the recently created Institut de Spéologie at Cluj and in 1927 he succeeded R. Jeannel as assistant director. He remained at his post when, following the Treaty of Vienna, a large part of Transylvania was ceded to Hungary and his Rumanian colleagues went into exile (1940-45). E. Racovitza, the founder and first director of the Institut, died in 1947, and political events compelled Chappuis to leave Rumania in 1948.

Until serious thyroid trouble put an end to strenuous activity, he was a great traveller. In 1921 he and A. David explored the region of the White Nile. In 1929 he joined R. Jeannel and Ch. Alluaud in an expedition to the Sahara. In 1931 he and Alluaud crossed the Sahara and collected extensively in the regions of the Upper Volta and Ivory Coast.

In 1932-33 he accompanied Jeannel and Arambourg on their expedition to the River Omo and climbed Mt. Elgon. He and his colleagues visited hundreds of caves in little-known or unexplored parts of Transylvania, notably in the Bihar Mountains, and in old Serbia.

A fuller account of his life, together with a complete list of his numerous scientific publications, will appear in a memorial part of the *Annales de Spéléologie*. He wrote the third volume of Thienemann's "Die Binnengewässer", entitled "Die Tierwelt der unterirdischen Gewässer" (Stuttgart, 1927). In the same year he also contributed the section on Anaspidacea to Kuikenthal and Krumbach's "Handbuch de Zoologie". He was an authority on various groups of freshwater and subterranean Crustacea, especially harpacticids, bathynellids and isopods. His discovery, in 1942, of the true habitat of *Bathynella* and other minute animals that occur sporadically in wells, springs or caves opened a new field of investigation. Since then numerous new or little-known interstitial animals, freshwater and marine, have been discovered in many parts of the world. Many of the Crustacea, including a European species of Mystacocarida, were described by Chappuis and his collaborators and his last years in France were exceedingly productive ones.

In 1922 he married Heidie Spinnler, of Basle; their son, Pierre, resides in Basle, and their daughter is married to an English architect.

ISABELLA GORDON

Dr. Gertrude L. Elles, M.B.E.

THE doyen of women geologists, Dr. Gertrude L. Elles, emeritus reader in the University of Cambridge and honorary Fellow of Newnham College, died at Helensburgh on November 18, in her eighty-ninth year. She entered Newnham as a scholar in 1891 and remained, with few interruptions, resident in Cambridge until a few weeks before her death.

She obtained first-class honours in Part II of the Natural Sciences Tripos (Geology) in 1895 and for the next few years was associated with Lapworth at Birmingham and with Törnquist and others in Sweden. This initiated the work on graptolites for which she is so widely known, and she soon com-

menced with Dame Ethel Shakespeare the preparation of the Palaeontographical Society's monograph on British graptolites under the editorship of Prof. Lapworth. The ten descriptive parts of this classic work appeared with extraordinary regularity between 1901 and 1914 and established her position as a world authority on these fossils. Of a dozen or so smaller publications on them, the most significant was her "Graptolite Faunas of the British Isles" (Geologists' Association, 1922), which has exercised a profound influence on subsequent work on their faunal succession and evolution.

Nevertheless, Dr. Elles's interest in fossils was pre-eminently that of the field geologist and stratigrapher, and, concurrently with her work on the graptolites, her investigations on Lower Palaeozoic stratigraphy in Wales and the Welsh Borderland resulted in several papers on the geology of areas around Ludlow, Conway, Bala and Builth. Relatively late in her career, she turned to a completely new field in 'hard-rock geology', and jointly with Prof. C. E. Tilley published a notable contribution on metamorphism in relation to structure in the Scottish Highlands.

Dr. Elles was closely associated with the Sedgwick Museum (or its forerunner, the Woodwardian Museum) for nearly seventy years. Her standing in the Department of Geology was formalized by her appointment, under the new statutes, to a University lectureship in 1926; ten years later, she became the first woman reader in the University. Few who have graduated in the Cambridge Department of Geology during this long period but were influenced by her enthusiasm as lecturer or supervisor; and many were drawn to Cambridge as postgraduate students to work under her direction. She inspired great affection among her colleagues, and as a teacher she will be remembered for her vitality, forthright manner and clarity of exposition.

She held the degree of doctor of science of Dublin and of Cambridge. When the Geological Society of London extended its fellowship to women in 1919, she was one of the small but distinguished group at once admitted, and she was in the same year the first woman to receive the Society's Murchison Medal. She was president of Section C (Geology) of the British Association in 1923.

O. M. B. BULMAN

NEWS and VIEWS

Royal Society:

New Gold Medal

THE Council of the Royal Society has accepted an offer by the Trustees of the Leverhulme Trust Fund to mark the occasion of the Royal Society's Tercentenary by the award of a gold medal. Under the terms of the offer, the medal is "for award by the Society, every three years, to the individual who in the opinion of its Council shall have made the most significant contribution in the field of pure or applied chemistry or engineering including chemical engineering. The medal, which will be in gold, will be accompanied by a monetary award of five hundred pounds". The Council has made the first award of the medal to Sir Cyril Hinshelwood, who retired as president of the Royal Society on November 30, for his outstanding contributions to physical chemistry.

Officers

SIR HOWARD FLOREY, president of the Royal Society, has appointed the following vice-presidents for the year ending November 30, 1961: Sir Alexander Fleck, treasurer of the Royal Society, formerly chairman of Imperial Chemical Industries, Ltd.; Sir Lindor Brown, biological secretary of the Royal Society, Waynflete professor of physiology in the University of Oxford; Sir William Hodge, physical secretary of the Royal Society, Lowndean professor of geometry and astronomy in the University of Cambridge; Sir Patrick Linstead, foreign secretary of the Royal Society, rector of the Imperial College of Science and Technology, London; Prof. T. M. Harris, professor of botany in the University of Reading; Dame Kathleen Lonsdale, professor of chemistry at University College, London.

The Gas Council's London Research Station :

Mr. G. U. Hopton

MR. G. U. HOPTON has been appointed the new director of the Gas Council's London Research Station at the Fulham Laboratories. He was senior research chemist of the North Thames Gas Board from 1952, until the retirement of Dr. R. H. Griffith last August, when he became acting director. Mr. Hopton gained a first-class honours degree in chemistry at Oxford and the same year joined the Gas Light and Coke Company. In 1936 he was awarded the MacNab Medal of the Institution of Chemical Engineers and in 1945 gained the H. E. Jones Medal of the Institution of Gas Engineers. From 1950 until this year he was chairman of the board of examiners of the Institution of Chemical Engineers. Mr. Hopton has also been vice-president of the Institution. He is a member of the board of studies in engineering of the National Council for Technological Awards.

British Museum (Natural History) : Appointments

THE Principal Trustees of the British Museum have appointed Dr. F. C. Fraser, keeper of zoology, and Mr. J. E. Dandy, keeper of botany, to be deputy chief scientific officers in the British Museum (Natural History). They have also appointed Mr. J. P. Doncaster to be keeper of the Department of Entomology in the British Museum (Natural History), in succession to Dr. W. E. China, who will retire on January 31; and Dr. J. P. Harding and Mr. J. F. Perkins to be deputy keepers in the Departments of Zoology and Entomology, respectively.

Mr. Doncaster, who has been a deputy keeper in the Department of Entomology since December 1955, was educated at Leighton Park School, Reading, and St. Catharine's College, Cambridge. After some years on entomological work at the Plant Virus Research Station, Cambridge, he entered the British Museum (Natural History) in 1937, to take charge of the newly formed Exhibition Section. During the War he was seconded to the Agricultural Research Council to work on the aphid vectors of potato viruses, returning to the Museum in 1945 to begin the re-designing and reconstruction of war-damaged exhibits. In 1951 he joined the staff of the Department of Entomology to take charge of the collections of Homoptera (Sternorhyncha) and Thysanoptera, and to reorganize the collections of Aphididae. His published works have dealt mainly with the systematics of aphids and their role as virus vectors.

Dr. Harding was educated at Torquay Grammar School, University College, Exeter, the University of Cincinnati, and King's College, Cambridge. Prior to joining the staff of the British Museum (Natural History) in 1937, Dr. Harding worked for a year as assistant naturalist in the Ministry of Agriculture and Fisheries. Dr. Harding is a carcinologist specializing in the Entomostraca, on which he has published many papers in journals of learned societies.

Mr. Perkins was educated at Newton College and the Imperial College of Science and Technology (Royal College of Science), London, graduating in 1932 and being awarded the Forbes Medal. He entered the British Museum (Natural History) in 1933, where he has worked on the parasitic Hymenoptera, and in particular Ichneumonidae. During the War he was seconded to the Ministry of Agriculture, where he was associated with some of the early trials of D.D.T. against crop pests. His published works have been concerned with the general classification

of the Ichneumonidae, and revisions of groups of this family particularly in relation to the British fauna.

Exhibition of The Institute of Physics and The Physical Society

IF one function of science is to enable us to rationalize our sense perceptions, we need instruments and apparatus to help us perceive; the coincidence of the pointer and scale is of profound importance. As our scientific knowledge ramifies and increases in complexity, demands upon apparatus for precise measurement and manipulation become more exacting. The manner in which this demand has been met so far will be clearly demonstrated at the annual exhibition to be held by The Institute of Physics and The Physical Society at The Royal Horticultural Society's Halls, Westminster, London, S.W.1, from January 16 until 1 p.m. on January 20. Lectures will be given by: Mr. F. S. Burt (Admiralty Research Laboratory) on "Hydrodynamics Research", on January 17; Dr. G. E. R. Deacon (National Institute of Oceanography) on "The Physics of the Ocean", on January 18; and Dr. F. P. Bowden (Laboratory for the Physics and Chemistry of Solids, Cambridge) on "Some Physical Problems in Travelling at Supersonic Speed", on January 19. These lectures will be at 5.45 p.m. The prize-giving of the Craftsmanship Competition will take place in the lecture theatre on January 19 at 3 p.m. The Society has published a *Handbook of Scientific Instruments and Apparatus* (price 6s., plus 2s. postage), which is a guide to the exhibits. It is also a reference book on recent developments in the design of physical apparatus; it provides a list of manufacturers and of recent scientific books. As a means of planning one's visit to the Exhibition, the handbook seems indispensable. Further information can be obtained from The Institute of Physics and The Physical Society, 47 Belgrave Square, London, S.W.1.

Institute of Information Scientists

A FULL syllabus for education in information work has now been prepared by the Institute of Information Scientists; it has also been approved by Aslib. Courses on "Collecting and Communicating Scientific Information" based on this syllabus have been arranged at the Northampton College of Advanced Technology, St. John Street, London, E.C.1, to start on January 24, and will comprise evening classes twice a week during two years. The Institute will hold (external) examinations, based on the syllabus, for the Certificate of the Institute, and will be set in two groups, at the end of 1961 and 1962, respectively. Details of the course may be obtained from the College, and other information from the honorary secretary of the Institute, J. Farradane, "Torrans", Crofton Road, Orpington, Kent.

Forest Research and Training Institute for Latin America

A focus for forest research and training in Latin America has been acquired with the permanent establishment—following four years on a temporary basis—of the Latin American Forestry Institute for Research and Training at the Forestry School of the University of Los Andes, Merida, Venezuela. A multilateral agreement has been reached between the Food and Agriculture Organization, under the aus-

pices of which the Institute will operate, the Government of Venezuela, and other interested member nations of the Organization. So far, Venezuela, Guatemala, Nicaragua, Panama, Peru, Colombia, France and the Netherlands have become party to the agreement. Several other countries are expected to join in the near future. The aims and functions of the Institute are fourfold: it will carry out research projects, particularly those of broad interest and of an applied nature which would contribute to the conservation, utilization and development of Latin American forest resources; it will organize forestry training courses in line with future demands for both Government and private foresters in Latin America; it will gather, classify and disseminate forestry information; and it will promote regional co-ordination of research by informing member Governments of forest research being carried out in Latin America.

Health Science Man-power in the United States

A SURVEY of the man-power needs in health science for the United States is to be carried out by the Federation of American Societies for Experimental Biology. Objectives of the survey will include: (1) an assessment of the present supply and demand for scientists in each of about twelve basic health fields; (2) projections of such supply and demand for the next 10-20 years; and (3) recommendations as to how the increased demand for these scientists may be met. Dr. John T. Cowles, director of educational planning for the health professions at the University of Pittsburgh, is director of the project. Dr. Lowell S. Levin has joined Dr. Cowles's staff in Pittsburgh to serve as full-time associate director of it. Some of the data being sought include: number of persons now employed, salary-levels, space requirements, current student enrolments, research expenditures, training programme income, instructional costs and student aid. The over-all project, which will require three to five years to complete, will be expanded from microbiology to include most, if not all, of the health science fields. The experimental phase of the project is being supported by an \$7,000 dollar grant from the National Institutes of Health. The University of Pittsburgh has been selected to carry out the survey because of its available personnel and electronic computer facilities which will be required.

Educational Film Centre, Ltd.

A NEW organization, the Educational Film Centre, Ltd., has recently been founded. Its directors are Maurice Goldsmith, formerly science editor at Unesco, John Halas and Joy Batchelor, animation film producers, and Dr. Roger Manvell, formerly director of the British Film Academy. The objects of the Centre include promoting the production of educational films, and specially of science-teaching films, sponsorship of research into the most useful forms and techniques for instructional films and their best use in the class-room, and publication of pamphlets and film-strips associated with the films produced and with the research projects undertaken by the Centre. The Centre is in close consultation with the Educational Foundation for Visual Aids. The initial aim is the production of a planned series of science-teaching films designed specifically for use in secondary modern schools. These films will be made in collaboration with representatives from science teachers' associations, who have already undertaken

to give advice and help. The Centre is to operate from Lysbeth House, 10a Soho Square, London, W.1.

Wallace and Darwin

MORE information about the theory of organic evolution put forward jointly by A. R. Wallace and Charles Darwin is contained in recent publications. In a recent issue of the *Proceedings of the Linnean Society of London* (171, Part 2, 139; 1960), Prof. C. F. A. Pantin introduces the essay prepared by Wallace in 1855 which served to stimulate Darwin to join him, and led to the publication of their famous paper of 1858. Mr. Tom Harrisson, curator of the Sarawak Museum, in a forthright article in the "Proceedings" of the Centenary and Bicentenary Congress of Biology held in Singapore during 1958, is concerned chiefly with Alfred Russel Wallace and a letter he wrote to Charles Darwin from Ternate in the Celebes in 1858. The author contrasts the background of these two men—Darwin, the son of wealthy parents, and Wallace, born of humble parentage. It was the Ternate letter, Mr. Harrisson claims, that forced Darwin's hand, for on its receipt "he had to speak or forever lose his place in the priorities of the new human thought".

In the fourth of his articles on Darwin's Notebooks on the Transmutation of Species, Sir Gavin de Beer deals with the Fourth Notebook, concerned with the period October 1838–July 10, 1839 (*Bulletin of the British Museum (Natural History)*, Historical Series. Vol. 2, No. 5. Pp. 151–183. (London: British Museum (Natural History), 1960.) 15s.). Darwin's Fourth Notebook on Transmutation of Species was written after he had read Malthus's "Essay on the Principle of Population" on October 3, 1838. Considering the importance of the influence which Malthus's book was thought (even by Darwin himself in later life) to have exerted on Darwin's work and ideas, it is significant that he devoted so little space to Malthus in his Notebook which he wrote immediately after reading his essay. The reason is that Darwin had already and independently thought out the principle of selection of favourable variations and seen the possibility that the transmutation of species might be explained by its means. What Malthus gave Darwin was evidence of the rigorousness of selection and of the inevitability of widespread mortality. To this concept Darwin introduced the notion of extinction as the extreme case of depopulation and the notion of variation; and he showed that he was well aware that this would lead to results very different from those which Malthus thought he had achieved.

Darwin's Original Papers

IN 1942 the Pilgrim Trust and the Darwin family presented to the University Library, Cambridge, and to Down House, the original papers of Charles Darwin. Those intended for Cambridge arrived at the Library after the War and have been bound in volumes representing as closely as possible the papers in the order in which Darwin left them. A detailed hand-list of the papers was made in 1955 by Miss R. V. C. Bailey and Miss J. S. Gosse for the use of scholars working on the papers in the University Library. This hand-list has now been published in view of its general interest, together with a subject index and an index of correspondents compiled by Miss G. M. B. Tyrer (Pp. 72. Cambridge: At the University Press, 1960. 10s.).

Preservation of Wild Animals in Asia

MUCH has been written in recent years on the threat of extermination hanging over much of the fauna of Africa and on possible methods of averting it. Less has been heard about the equally pressing danger to the fauna of other parts of the world. The timely appearance of a report on some animals of the Middle East and southern Asia which are threatened with extermination entitled "A Look at Threatened Species", by L. M. Talbot (*Oryx*, the Journal of the Fauna Preservation Society, 5, Nos. 4 and 5, 157; May 1960), is therefore particularly welcome. The report is based on information collected during an extensive journey of reconnaissance in 1955 extending from Libya to Formosa. The investigation was concerned principally with the past and present status of the three species of Asiatic rhinoceros, the Indian lion, the Arabian oryx, and the Syrian wild ass; but the report also deals with many other species. It is a most interesting and well-written document that considers in some detail such matters as wild-life habitats and land-use, and gives an account of such reserves and parks as there are in the territories visited. One of the largest problems facing conservation is the lack of trained personnel. In most former 'Colonial' territories conservation and management were carried out by men from the colonizing country. When they departed, the country was left with very few people with any training at all in conservation matters. Nevertheless, although in many places there has been, and still is, much wanton destruction, a real effort is being made in others at conserving what is left. This report will strengthen the hand of the International Union for the Conservation of Nature in its efforts to help those concerned in preventing the final extermination of a number of interesting species of animals.

Geomorphological Abstracts

As a guide to the very scattered literature of interest to geomorphologists, a small journal of abstracts, in an attractive format, has recently been produced by a group of British geographers. In the first two numbers, for June and September 1960, abstracts are given of 136 recent papers, mainly works in English-language periodicals (No. 1; June 1960. Pp. 23. Published four times a year in March, June, September and December). At present some 120 journals are covered, and it is hoped to increase this number as circumstances permit. *Geomorphological Abstracts* will be published quarterly, and can be obtained from K. M. Clayton, Department of Geography, London School of Economics, Houghton Street, London, W.C.2, price 16s. per annum, post paid.

Canadian Museum Publications

THE National Museum of Canada has added to its guide-books two publications which should be well received by visitors to the Museum. The first, "Canadian Atlantic Sea Shells", by E. L. Bousfield, is an illustrated account in English of shell-bearing invertebrate animals commonly encountered on the beaches or in shallow waters of the Canadian Atlantic coast from the Strait of Belle Isle and the St. Lawrence estuary on the north to the ocean coasts of Newfoundland and Nova Scotia and the Bay of Fundy in the south. Altogether, 150 sea shells are described (Pp. v+72, 13 plates. Ottawa: Queen's Printer, 1960. 1 dollar). The second, "Les Mammifères du Canada", by Austin W. Cameron, contains

descriptions in French of the mammals of Canada, each description being accompanied by a line drawing prepared by John Crosby (Pp. 89. Ottawa: Queen's Printer, 1960. 50 cents).

Scientific Instrument Manufacturers' Association

THE Scientific Instrument Manufacturers' Association has published a booklet, "Careers in the Scientific Instrument Industry", providing a well-illustrated summary of what a new entrant into the industry can expect to find and what his work and training may be like (Pp. 20. London: Scientific Instrument Manufacturers' Association of Great Britain, 1960). The launching of the booklet has been encouraged by the rapidly increasing number of apprenticeship certificates issued by the Association's members under their endorsement scheme in recent years. In 1958, 52 certificates were endorsed, 64 in 1959, and 82 in the first nine months of 1960, or at a rate double that of 1958. The endorsement ensures that certain standards of training with the appropriate equipment are the foundation of the apprentice's certificate, and provide him with the start to a career in the scientific instrument manufacturing industry. The booklet can be obtained from the Scientific Instrument Manufacturers' Association, 20 Queen Anne Street, London, W.1.

Information on Atomic Energy in Britain

UNDER the title "A Guide to Information on Atomic Energy in Britain", the Central Office of Information has issued an illustrated select list of British books, periodicals, reports, films, photographs and display materials, describing the latest nuclear developments in the United Kingdom, which was originally compiled for specialized and prestige distribution overseas (Pp. 64. London: H.M. Stationery Office, 1960. 5s. net). The list was prepared with the co-operation of the United Kingdom Atomic Energy Authority. The material is arranged under visual aids; general publications; serial publications; the power programme and nuclear engineering; radioisotopes; nuclear physics; and radiation hazards and protection. Books for the specialist and for the general reader are distinguished. There are also further lists of the Atomic Energy Authority's unclassified publications (including a list of depository libraries in the United Kingdom), and of publications covering legislation in the United Kingdom and co-operation with other countries.

Restoration of a Silk Flag

THE *Museum Journal* of November, in an article by Mr. Harry Wandrus, describes an economical method for the treatment of deteriorating silk flags. The flags were the property of the State of Ohio and most of them were of 'weighted' silk, that is, they contained chlorides or sulphates of magnesium, tin, iron or aluminium. Unfortunately, these chemicals have the effect of causing an early deterioration of the silk, which then crumbles and powders. The essence of the process is to soften the old flag with water and carefully assemble the parts in their correct positions on a flat table ready for a white silk chiffon backing. This backing should be neatly arranged over the flag and fastened with a 5 per cent solution of polyvinyl alcohol. The flag will then hang well in a vertical position. Full details of the process are given.

Atomic Weight of Silver

SILVER is an important secondary standard of atomic weights, the values of these for many elements having been determined with reference to silver. The natural element contains two isotopes, 107 and 109, and the average atomic weight has been accepted as 107.880, on the chemical scale. A mass-spectrometer investigation by W. R. Shields, D. N. Craig and V. H. Diebeler, of the Bureau of Standards, Washington, is reported in the October issue of the *Journal of the American Chemical Society* (p. 5033). It was found that no variation in abundance ratio occurred in six specimens of natural silver, but a seventh, from Cobalt, Ontario, showed a significant deviation. The values of the atomic weight found were, on the physical scale ($^{16}\text{O} = 16$) 107.9028 ± 0.0013 , on the chemical scale ($\text{O} = 16$) 107.8731 ± 0.0020 , and on the proposed unified scale ($^{12}\text{C} = 12$) 107.8685 ± 0.0013 . It is seen that the chemical value differs appreciably from 107.880.

Binocular Depth Perception

ONE of the difficulties in studying depth perception is to isolate the different factors that contribute to the three-dimensional effect, and in particular to separate the binocular from the monocular cues. A highly original method of achieving this separation has been developed at the Bell Telephone Laboratories by B. Julesz, and, under the heading "Binocular Depth Perception of Computer-Generated Patterns", the subject is discussed in a recent issue of *The Bell System Technical Journal* (39, 1125; 1960). In this method the two pictures to be viewed in a stereoscope consist of a random arrangement of black, white and grey dots. These two micropatterns are similar in dot distribution except for a central area where, for example, a square-shaped region is given a uniform horizontal displacement. Each pattern by itself has a completely random appearance, but when viewed in a stereoscope, the parallax produced by the lateral displacement causes the central square region to appear either in front of or behind the surround, depending on the direction of displacement. Several interesting features emerge from this method of presentation in which monocular cues are eliminated. For example, several seconds or even minutes may elapse before the depth effect is perceived, presumably while the eye and brain are searching the pattern and assimilating the information being presented to the subject. When the viewing is repeated, the perception-time may be shortened as the process of learning facilitates recognition of the pattern. The effect of varying the contrast of the pattern, its sharpness, different perturbations of the pattern and the introduction of a monocularly recognizable pattern have all been studied to see how far the depth effect is enhanced, although just what is meant by depth enhancement is not immediately obvious.

The Night Sky in January

FULL moon occurs on Jan. 1d. 23h. 06m. U.T., new moon on Jan. 16d. 21h. 30m. and full moon on Jan. 31d. 18h. 47m. The following conjunctions with the Moon take place: Jan. 1d. 17h., Mars 8° N.; Jan. 20d. 05h., Venus 0.6° N.; Jan. 26d. 13h., Aldebaran 0.3° S.; Jan. 28d. 07h., Mars 8° N. Mercury will be visible as an evening star near the end of the month, setting about one and a half hours after the Sun. Venus is an evening star, and is favourably placed for observation. Venus sets at 20h. 00m., 20h. 35m.

and 21h. 15m. on January 1, 15 and 31, respectively, about four hours after the Sun. During the month its distance from the Earth decreases from 83 to 63 million miles, the visible portion of the apparent disk from 0.639 to 0.499, and its stellar magnitude from -3.7 to -4.1 . Mars is above the horizon all night on January 1, and sets at 7h. 10m. and 6h. 5m. on January 15 and 31, respectively. Mars is very conveniently situated for observation. It is at a distance of 61 million miles from the Earth on January 15, and its stellar magnitude is -1.0 . Jupiter and Saturn are too close to the Sun for observation. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Jan. 7d. 5h. 09.8m., 59 Leo. (*R*); Jan. 24d. 19h. 57.2m., $+11^\circ 445$ (*D*); Jan. 26d. 23h. 59.6m., 318 B. Tau. (*D*). *D* and *R* refer to disappearance and reappearance, respectively. The Quadrantid meteors are active on January 3, but conditions are unfavourable for observation. The Earth is at perihelion on January 2, its distance from the Sun being 91.4 million miles.

Announcements

DR. DETLEV BRONK, president of the Rockefeller Institute, has been elected an honorary member of the Brazilian Academy of Science and has been awarded an honorary doctorate of the University of Brazil.

DR. AMYAND DAVID BUCKINGHAM has been awarded the Harrison Memorial Prize for 1959 in consideration of his work on solvent effects on molecular spectra and the theory of pressure-induced spectra. Dr. Buckingham is at present in the Department of Inorganic Chemistry, University of Oxford.

DR. H. HAROLD HUME, of Gainesville, Florida, has been awarded a gold Veitch Memorial Medal by the Council of the Royal Horticultural Society for his work on horticulture and in particular for his work in connexion with camellias.

THE Systematics Association are arranging a meeting on "Multivariate Methods in Taxonomy" to be held in the Department of Botany, the University of Southampton, during April 24-25, 1961. Further information can be obtained from Dr. J. M. Lambert, Department of Botany, University of Southampton.

"Radio Techniques and Space Research" will be the theme of next year's British Institution of Radio Engineers' Convention which will take place during July 5-9, 1961, at the University of Oxford. The Convention will contain at least six sessions, provisionally entitled: "Review of the Role of Radio Techniques in Space Research"; "Satellite Engineering Problems"; "Extra-terrestrial Measurements"; "Telemetry"; "Techniques in Radio Astronomy"; "Satellites in Terrestrial Communications". The Convention Committee has invited offers for papers, and these should be addressed to the British Institution of Radio Engineers, 9 Bedford Square, London, W.C.1.

THE Chemical Society, Burlington House, London, W.1, has published "Periodicals in the Chemical Society Library", giving the complete periodical holdings in the Library (Pp. 48. London: The Chemical Society, 1960. 5s. post paid). This will be useful not only to members of the Society but also to librarians and users of chemical literature generally.

ORGANIZATION OF SCIENTIFIC RESEARCH IN LATIN AMERICA

A REGIONAL meeting to discuss the organization of scientific research in Latin America was held during October 3-7 in the Central University of Venezuela, Caracas. The meeting was arranged by the Unesco Science Co-operation Office for Latin America, under the patronage of the Ministry of Education and the University of Venezuela. Heads of national research councils, rectors of universities, deans of science faculties and senior scientists from Argentina, Bolivia, Brazil, Chile, Colombia, Cuba, Ecuador, Mexico, Peru, Uruguay and Venezuela had been invited to attend, and the World Health Organization and the National Academy of Sciences of the United States sent observers. The meeting was held at the Central University.

The president of the Republic, Sr. Rómulo Betancourt, spoke briefly at the opening ceremony, welcoming the delegates with the assurance that they would find in the Venezuela of to-day complete freedom for the development of scientific research. Among other speakers were Dr. Establier, head of the Unesco Science Co-operation Office for Latin America; Dr. Rafael Pizani, Minister for Education, and Dr. Francisco De Venanzi, rector of the Central University.

The meeting elected Dr. Venanzi as its chairman. The working sessions were opened by a review of the general tendencies of scientific research in Latin America by Prof. Bernardo Houssay, president of the Council for Scientific and Technical Research of Argentina. This paper provoked a valuable discussion which formed a background for the other papers presented at the meeting.

The paper by Dr. David Stitchkin, rector of the University of Concepción, Chile, on funds available for scientific research, with special reference to equipment, was the one which caused least discussion, since the meeting was unanimous in concluding that the amounts at present available were notably insufficient. It was recommended that Governments should accept as a target the allocation of 2 per cent of the national budget for scientific research.

During the discussion of the paper by Dr. Mario Gonzalez (Cuba) on the basic and applied sciences, it became clear that the meeting did not wish to emphasize the distinction between the two, and preferred to think of science as a whole, recommending that firms in industry and agriculture should strengthen their links with research and teaching institutions in view of the profound effect which science has on modern commercial life.

Prof. Houssay introduced the question of national research councils, which exist in only a very few Latin-American countries, including the Argentine, Brazil and Mexico. The other Governments of the region were recommended to give serious thought to the advantages of establishing research councils, and Unesco was asked to provide information to Governments about the functions and possible types of organization of research councils.

Dr. Marcel Roche, director of the Venezuelan Institute of Scientific Research, presented a paper on

the career of the research worker. He analysed and compared the careers offered by the research councils of Argentina, France and Venezuela. It was thought that the arrangements adopted by the Argentine and Venezuelan Councils, whereby their staffs were able simultaneously to accept teaching posts, was valuable in the Latin-American scene, since it made maximum use of the small scientific man-power available, and kept the research worker in touch with universities and youth. This subject was very closely related to the next one discussed, the shortage of teaching and research personnel in Latin America, which was introduced by Dr. Rodolfo Talice, dean of the Faculty of Science in the University of Montevideo.

One of the topics of greatest interest at the meeting was the paper by Dr. Paulo Sawaya, dean of the Faculty of Philosophy of the University of São Paulo, on the results of the adoption in certain universities and institutions of the full-time system. Most universities and research organizations permit their staffs to hold one or more posts outside the organization, and the virtues and vices of this system form one of the most hotly debated subjects in scientific circles in Latin America. The meeting recommended that Governments and universities should establish the full-time system as the ideal in research and higher teaching posts, and that they should provide salaries and working conditions adequate for this purpose.

Unesco has encouraged and assisted the formation of regional research centres, such as that for mathematics in Buenos Aires, and of groupings of research centres, such as the Latin-American Council for Cosmic Radiation. Dr. Ismael Escobar, head of the Cosmic Ray Physics Laboratory at Chacaltaya, Bolivia, introduced this topic, the discussion of which led the meeting to call on Unesco to continue its efforts in this field, so that teams of research workers might be brought together, animated by the desire to achieve Latin-American unity in research.

Dr. De Venanzi analysed the attitudes of Governments and of public opinion towards scientific research problems in Latin America. Though much improvement has occurred in the past few years, a great deal remains to be done. The meeting felt that the Press, radio and television had a paramount part to play, and hoped that ways could be found to establish training in scientific journalism. In this connexion, delegates were happy to note the complete and accurate coverage of the meeting in the Caracas Press.

In Latin America, fellowships tenable in more scientifically developed areas will, for some time to come, provide the principal source of higher training for research workers in many fields. Dr. E. Beltran, Under-Secretary for Forestry and Game Resources in Mexico, discussed the subject in all its aspects. An increase in the number of fellowships granted by governments and other agencies was recommended, as well as greater emphasis on instruction in foreign

languages, since language deficiencies frequently prevented full benefit from fellowships. The paper by Dr. M. A. Garrido Malo, dean of the Science Faculty in San Marcos University, Lima, was on a closely allied subject—exchange of scientists between Latin-American countries. Unesco was asked to publish its *Boletín* with greater frequency, so that news of courses, special facilities, visits of foreign scientists, etc., might be more rapidly disseminated, and all laboratories were exhorted to use to the utmost the facilities offered.

The subject of scientific documentation in Latin America was introduced by Dr. Manuel Sadosky, vice-dean of the Science Faculty in the University of Buenos Aires. A lengthy discussion led to a series of recommendations: that Unesco should make a survey of scientific journals in Latin America, with the object of formulating a plan for rationalizing them; that the Mexican Scientific Documentation Centre should make its services more easily available to scientists in other countries; that more national scientific documentation centres should be established, that Governments should grant free postal services to scientific journals; and that financial

help might be given to a select number of journals.

The final subject on the agenda was a review of Unesco's science programmes, particularly that of the Latin American Science Co-operation Office in Montevideo. Dr. Establier described proposals to be debated at the general conference of the Organization held in Paris in November, and also outlined a series of long-term projects which might be undertaken by the Montevideo office. Among these was one for an International Andean Year, during which teams of specialists in different fields would attack the problems of this vast mountain chain which so profoundly affects living conditions in those countries through whose territories it runs. Another proposal was for a full-scale operation towards rationalizing scientific journals. A third would deal with the problems of the unproductive areas of the seas, lakes and rivers of the continent. At the end of this discussion Dr. Establier received the warm congratulations of the meeting, both for the way he has directed Unesco's science activities in Latin America, and for the organization of the meeting.

B. A. HOUSSAY

INTERNATIONAL OPERATIONAL RESEARCH

FROM its War-time start in Britain, operational research has become an international movement. The first conference on this basis was held three years ago at Oxford. It led to the establishment of the International Federation of Operational Research Societies, of which the chief architect was Sir Charles Goodeve, who was elected its first general secretary. Under his guidance the Federation continues to expand. Great Britain has acted as the Federation's first 'foster' society, an office which shortly passes to America; and France was designated 'host' society for the second of the triennial conferences, called at Aix-en-Provence during September 5-9. The Société Française de Recherche Opérationnelle has discharged its duties with grace and efficiency, at a conference presided over by its own president, Prof. G. T. Guilbaud.

The Second International Conference on Operational Research had the object of surveying the whole scene, and its organizers limited the attendance to 350 delegates. Representation at the national level was strictly allocated according to the sizes of national societies, who themselves had the invidious task of selecting their delegations from long lists of applicants. The programme was determined in outline by a committee which appointed leading workers in this field as sponsors of more than twenty sessions; each sponsor was responsible for designing and presenting his own session, for inviting some papers, for selecting others from among those submitted freely, and for taking the chair at his session at Aix-en-Provence. These arrangements led to a more tightly controlled conference than is customary at this level, and were intended to produce a coherent pattern, high-quality material, and authoritative discussion.

Delegates arrived from no less than twenty-three countries; and although two-thirds of them were drawn from America, Britain and France, there was

plenty of evidence that significant operational research efforts have been mounted in at least a dozen more countries. The extent of the applications of operational research to-day might have surprised those who first embarked on the attempt to apply the methods of science to the strategic problems of war. But there are strategic problems in all managerial situations, and eighty papers presented at Aix-en-Provence attest to the fact that operational research has by now penetrated into the intricacies of most of them.

The conference opened with a plenary session dealing with the methodological aspects of operational research. Whispers were heard complaining that once again the subject had succumbed to mere introspection, to a self-conscious preoccupation with its own anatomy. Most scientists in the field of operational research would agree, however, that a subject devoted to scientific investigation of the methods of management has something to gain from the examination of its own. Thus it proved. The session brought out clearly the fact that the goals of an organization are various and not necessarily consistent, that they are constantly changing, and that they reflect a process of learning to survive by adaptation. It follows that crude statements of aim, such as 'maximum profit', which have often been naively emulated by equally crude scientific models, are inadequate. There are always ways of estimating and comparing organizational efficiency, but they require experimentation on possible models and not merely experimentation within some plausible model. The sensitivity of a top-level decision to explicit assumptions about likely circumstances is itself an object of study; but its sensitivity to implicit assumptions about goals is still more important. For this reason the model of an adaptive organism adjusting itself to its environment is valuable, and much was said about attempts to use scientific descriptions of biological learning and

goal-seeking processes as models of business behaviour.

The first group of parallel sessions then set out to discuss two general problems and five areas of application. Six papers were presented dealing with new mathematical methods: they concerned especially the use of the theory of graphs in studying supply networks, and various treatments of the problems of sequential decision. Another group of papers dealt briefly with the question of controlling production, but without much originality. The areas of application were: transport, oil, power, steel and local government. Examples of transport operations by road, rail and air were given in which operational research had solved the strategic problems of scheduling fleets, and of choosing between alternative policies, for example, in overhaul, cargo carried and design. The oil industry put forward studies of the flow of traffic and the problems of stock-holding, and of the selection of investments. There were three papers in the session on power dealing with the operation of nuclear reactors, and studies were also presented of the central planning of an atomic energy industry and of an electricity distribution system. From the steel industry there were discussions of the control of spare parts and of the unloading of ore, and a study of track times. The local government session was devoted to city and land-use planning, and included a consideration of a city as a teleological mechanism generating its objectives intrinsically.

The formal sessions were broken up by a series of discussion groups. These were often extremely spirited conversations. They dealt, for example, with the organization of operational research, with its future needs, and with education—the latter subject leading to a considerable clash about the role of the universities and possible syllabuses. One group discussed economic decisions that could involve loss of life, and two more the allied techniques of operational gaming and of simulation. There was a meeting on operational research for under-developed countries. But perhaps the most remarkable session of all dealt with operational research at the top-decision-making level in industry. This involved some of the most forceful interchanges of the whole conference, and continued all day—although it was billed to last for the morning only. The discussion was too frank, too fast, and too heated ever to reach the printed proceedings: an added reason for the agreement of the main protagonists that this day alone had been worth the journey to France.

At this point, the second plenary session was held, to consider the relationship between operational research and computers. It was held that the existence of these machines, considered properly as logical engines rather than as calculators, had enabled operational research to forge new tools. Those discussed were a computer language for the automatic programming of simulations, which had quartered the time required to prepare an intricate programme, and a computer analysis of the field of heuristic decision processes. Secondly, however, computer applications themselves received benefit from operational research assistance. In this area, a mathematical model was presented for the optimal storage and retrieval of information, and an operational research survey was made of the factors involved in the introduction of on-line computers for controlling production.

The second series of parallel sessions included two general problem areas, those of inventory control theory and mathematical programming, and descriptions of operational research in three applied fields; mining, war and national government. Inventory theory is by now an extensively explored topic, but seven more contributions were made dealing with particular aspects of the problem. There were nine contributions also to the subject which began as linear programming, but which has long since been extended to such cases as the linear programme under uncertainty, various non-linear models, and quadratic programming—all discussed here. In the mining session, a general account of operational research at the National Coal Board in Britain was presented, as well as papers on the determination of optimal mining limits and the study of pit haulage. The presentation of military applications was necessarily restricted, but the relevance of the theory of games was discussed, as well as problems of communications and stock-holding policy. The growing effort in operational research at the national level was well expressed in various papers dealing with the whole economic system of a country, with national planning in India, with the co-ordination of investment in transport, and with social decision-making.

The third and last plenary session was concerned with human factors. Hospitals were considered as viable organisms, according to an adaptive model reminiscent of the methodological talk at the beginning of the week, and there were other papers on the human element in decision systems. A doleful note was sounded at the end of a strenuous conference by the report of some interesting research into the acceptance of solutions. Teams involved in business gaming were presented with the mathematically optimal strategy for their game after they had become implicated in the play; but in no case could any means be found by which they could be persuaded to use it.

The conference was closed with an address by Sir Charles Goodeve, who characteristically eschewed the usual valedictory platitudes. Instead, he issued a considerable challenge to the movement to play a bigger part in the social field, by bringing operational research to bear on the problem of evaluating alternative policies by developing a measure for human happiness. His address is reported *in extenso* elsewhere¹, and it will be interesting to see what fruit it has borne when the Third International Conference on Operational Research meets in Oslo in 1963, when the Norwegian society is expected to be host.

The proceedings reported here were set in the familiar context of receptions, tours, committee meetings, and arbitrarily arranged discussion groups—some of which lasted until dawn. Enthusiasm was a keynote of the assembly, as befits a young endeavour, and it was quite evident that much important operational research is being done that does not reach print. The first reason for this is an occupational hazard of the work: the advisors of management cannot readily air the secrets of institutional policy in public. But the second reason seems to be the convention that reports of operational research ought to include wads of respectable mathematics, whereas in real life the mathematics involved in operational research are often trivial.

Much was said at Aix-en-Provence publicly to acknowledge this fact, and to emphasize again the approaches for which operational research has always stood: scientific method, with its insistence on

measurement, experimentation and logical inquiry; interdisciplinary collaboration; above all, the seeking of usable insights rather than the production of abstract and possibly sterile formulae. This reaffirmation should do something to increase the supply of good literature on operational research. It will

certainly encourage those whose intentions are concentrated whole-heartedly on the essentially practical task of helping policy-makers reduce the influence of chance on the outcomes of their decisions.

STAFFORD BEER

BIOLOGICAL STRUCTURE AND FUNCTION

IN 1956, the International Union of Biological Sciences decided to set up a Biochemistry Section Committee which would be a co-ordinating committee between itself and the International Union of Biochemistry. One of the main functions of this Committee is to make recommendations to both Unions for international symposia, embracing subjects in which both biochemistry and the biological sciences are combining to produce a rapidly expanding sphere of knowledge; on this basis the subject "Biological Structure and Function" was chosen for the first joint symposium which was held at the Wenner-Grens Institute, Stockholm, during September 12-17. About 150 scientists attended the symposium, at which 72 members from 11 different countries presented invited papers to the seven sections of the symposium.

The first section was on macromolecular structure and function (chairman, A. Tiselius). Dr. J. C. Kendrew (Cambridge) described with great clarity the work which he has carried out on the elucidation of the structure of myoglobin, and Dr. P. A. Albertsson (Uppsala) discussed a new technique for separating macromolecules by partitioning them in aqueous two-phase systems containing polymers such as dextran and polyethylene glycol. This method has great possibilities in, for example, purifying viruses and separating different sized fragments of disintegrated mitochondria and chloroplasts. The second day, devoted to the subject of microsomes and protein synthesis, was memorable for a masterly discussion of the endoplasmic reticulum by the chairman, Dr. K. R. Porter (New York), which culminated in a series of electron micrographs which clearly demonstrated the existence of this structure in plant cells. In the more biochemical section the emphasis was on the role of ribonucleoprotein particles in protein synthesis.

Mitochondrial structure and function were discussed on the third day (chairman, O. Lindberg). At the moment, two subjects appear to polarize the interest of the various investigators studying the relationship between mitochondrial structure and function. One is the phenomenon of mitochondrial swelling. It seems, however, that different lines of approach are being followed by various laboratories. On one hand, swelling and shrinking are related to the transition of mitochondria from one to another well-defined functional state, for example, from a state of full respiration where the mitochondria are found to shrink, to a state in which the respiration is limited by the absence of phosphate acceptor and where the mitochondria are inclined to swell. On the other hand, mitochondrial swelling is considered to be the result of a more complete change of the normal structure with a loss of most of the mitochondrial functions; the inhibition of the swelling by

different agents or the reverse of swelling by way of a 'contraction' of the swollen mitochondria are followed as means to define the physiological implications of the phenomenon. The other topic, to which numerous papers were devoted, was the mechanism of electron transport and phosphorylation in the diphosphopyridine nucleotide-flavin region of the respiratory chain. The interest in this point was raised both because of the finding that in the presence of flavo-substrates a reversal of electron transfer could take place by way of reactions requiring high-energy phosphate, and because of the suggestion that this phenomenon could be related to an adenosine triphosphate activation of succinate oxidation, which on the other hand is not inhibited by uncoupling agents. It seems that work on these two reactions may provide a good deal of information on the question of the synthesis and utilization of the high-energy compounds during the operation, both in the forward and backward directions, of the terminal part of the respiratory chain.

In the morning session on chloroplast and chromatophore structure and function (chairman, T. W. Goodwin), electron micrographs of chromatophores isolated from both purple and green photosynthetic bacteria were shown by Drs. A. W. Frenkel (Minneapolis) and J. A. Bergeron (Upton, N.Y.), and Dr. M. D. Kamen (Waltham) speculated ingeniously on the primary act of photosynthesis. Later in the day Dr. D. I. Arnon (Berkeley) described his latest investigations on photosynthesis in cell-free systems of *Chromatium* and Dr. Birgit Vennesland (Chicago) gave her views on photophosphorylation with particular reference to the possible role of a 'nascent formate' intermediate, recently postulated by Warburg. The developmental physiologists discussed intact cellular structure and function on the morning of the fifth day, under the chairmanship of Prof. J. Runnstrom. The topics discussed ranged from 'mitosis', when Dr. D. Mazia described it in terms of a multitude of individual reactions co-ordinated into a fixed time pattern, to electron microscopy studies on ciliary and flagellar movements (B. Afzelius).

In the afternoon an important session on polysaccharides (chairman, G. Blax) included lectures by Dr. S. Hestrin (Jerusalem) on "The Growth of Saccharide Macromolecules" and by Dr. A. Dorfman (Chicago) on "The Acid Mucopolysaccharides of Connective Tissues", and concluded with another important paper on technique from Prof. Tiselius's laboratory, when Dr. P. Flodin described the gel-filtration method for separation of oligosaccharides.

The final session on specific membrane transport and its adaptation (chairman, B. D. Davis) produced further lively discussion, and the closing half-hour

was a salutary reminder that, in spite of the mass of information imparted during the week, our knowledge of the relationship between structure and function is still fragmentary—apparently two currently irreconcilable views are held on the mechanism of amoeboid movement.

The arrangements made by Prof. O. Lindberg and his colleagues in the Wenner-Grens Institute for this symposium were superb, and, thanks to their hard work and genius for organization, everything moved smoothly. Furthermore, the Wenner-Gren Foundation generously supported the symposium financially, and without its aid its existence would have been highly problematical. As could well be imagined, remembering the nationality of our hosts, the social side of the symposium was not neglected and highlights

included a banquet in Skansen and a visit to a performance of Pergolesi's "The Music Master" at the famous seventeenth-century Drottningholm Theatre. A specially delightful feature was that all foreign delegates spent at least one evening in a Swedish home.

The International Union of Biochemistry and the International Union of Biological Sciences are truly grateful to their Swedish hosts for arranging the first joint symposium, and hope that this Stockholm symposium will be the forerunner of similar international symposia based on fruitful co-operation between biochemists and biologists from all nations. It is hoped to publish the proceedings of the symposium in book form in the near future.

T. W. GOODWIN

POWDERS IN INDUSTRY

SIR ALEXANDER FLECK, the president of the Society of Chemical Industry, in opening the first symposium of the Surface Activity Group of the Society of Chemical Industry held during September 29–30, commented on the many imperfectly understood problems of physics and physical chemistry relating to industrial applications of powders, and referred to the largely empirical nature of many old-established manufacturing processes involving powders. "In recent years, however", he said, "application of the growing body of knowledge on the surface properties of powders has led to striking improvements in both processes and products and will undoubtedly lead to further developments, including the foundation of new industries".

In the words of Dr. M. G. Fleming, chairman of the organizing committee, the subject of powders was chosen for the symposium because so many industries make or use powders either as raw materials, intermediates or final products, many manufacturers being unaware of developments in otherwise unrelated industries which could assist them. The programme, he said, was planned to "sketch in the background and define the fundamental terms; next examine the particular requirements and problems of a diverse group of industries, and, finally, correlate these specialized applications, underlining their contiguity and exposing the shortcomings in our basic knowledge of the subject".

A laudable aim, but the event left the impression of unevenness and there were marked swings in the discussion from academic argument concerning, for example, the meaning of surface tension, to some severely practical details of powder processing. This was perhaps the inevitable result of covering so wide a field, theoretical and practical, in a relatively short time, but there was great value in bringing together so much material, the sequential grouping of which proved admirable.

Thirty-one authors contributed in the four sections, which covered "Principles of Production", "Properties of Powders", "Properties of Powders utilized in Industrial Fields", and "Principles of Application and Problems for the Future". There were seven sessions, each with its own chairman and an introducer, who presented the papers as a group on behalf of the authors

The papers of the first two sections concerned powder production by milling and by controlled precipitation, and the recovery and processing of natural powders; the surface energy of solids, adsorptive properties of powders, adhesion between particles, particle size, shape and surface area, and the electrical and flow-properties of powders. These together provided an excellent general background against which to study papers in the industrial section covering pigments and fillers in paints, printing inks, rubber and plastics (including a paper on whiting); powders as used in building cements, ceramics, bituminous road materials, cosmetics, detergents, pharmaceuticals, pesticides, paper, drilling fluids, and explosives; and problems of mineral dressing, soil mechanics, powder metallurgy, and coal and smokeless fuel production.

The papers revealed extensive basic research, much of it in relation to particular practical problems, and there was much evidence of considerable skill in process manipulation based on experience and technical appraisal of the products. In a brief report it is, however, impossible to give details of the numerous problems in powder production, manufacture and use, calling for further attention, or on which more fundamental knowledge would appear to be needed.

On the production side there were many references to the inefficiency of powder handling machines, particularly grinding mills (better understanding of energy relationships could lead to new methods of grinding), and to the unknowns in present methods of powder drying and powder size classification processes.

From the papers covering numerous industrial uses it was clear that while many of the outstanding problems are specific to particular industries, work in one field is not always being fully utilized in others. On the other hand, techniques of study successful in one industrial context can be unsuited to different materials and applications. For example, methods of particle-size determination adequate for size-ranges down to, say, one micron, giving useful information for particular applications, may be quite unsuitable for the much smaller particles sometimes involved in other types of product.

There is also the problem of how to measure effective or operative particle sizes, in particular

environments, for while knowledge of the geometry of individual primary particles is valuable, frequently the operative unit is an agglomerate, flocculate or cluster of particles. Often information about what is happening to the constituent particles in an industrial product has to be deduced from the rheological, mechanical or other properties of that product, there being an inadequacy of methods for directly observing the behaviour of particles within the mass.

In many industrial applications much more information is required about the interplay of particle and particle; about the behaviour of particles distributed in gas or liquid in various concentrations in relation to the behaviour of single particles in the same environments; also about the nature of the bond between such particles and the surrounding medium, not only in the static product, but also during the various processes involved in its application or use and subsequent life.

What is the present state of basic knowledge about powders? Here the conference was greatly assisted by the surveys made in the final section, with their collected information on well-established physico-chemical principles, and on the forces known to operate in dry or wet powders. Careful consideration of such information in relation to particular systems could, it was suggested, indicate possible means of controlling the mechanical behaviour of powders or suspensions.

There were calls for more information on the fundamentals of powder formation, and of the flow properties, internal packing, etc., of powders; also on the molecular origin of electrostatic charges, adhesion between particles, and the cohesion of the mass. There were indications of the kinds of basic work needed to improve understanding of the factors affecting dispersion and flocculation of particles in solid/liquid systems, involving the inherent surface chemistry of solids, adsorption, chemisorption, etc., and the fine-structure of particles relative to methods (for example, adsorption methods) of measuring 'surface area'. Recent rapid advances in microscopy, and in electron microscopy in particular, were noted, with the suggestion that microscopists should seek still further to improve their techniques.

To summarize, the symposium brought together a mass of material, fundamental and practical. It revealed the 'zones of ignorance' and the kind of investigations required for further advance. Individual powder-using industries can be expected to continue the search for new basic knowledge pertinent to the solution of their own problems, but their task would be facilitated by more extensive fundamental studies at the universities and in central research organizations. The field having been so well surveyed, it would be well for the participants to meet again in two or three years time to examine progress.

S. H. BELL

COMPOSITION OF MILK IN THE UNITED KINGDOM

UNTIL quite recently the quality of milk has been judged mainly on its fat content, but in the past thirty years an increased understanding of the principles of nutrition has made it clear that the most important constituents of milk are not the fats but the proteins, minerals and water-soluble vitamins which are, of course, to be found in the non-fatty solids portion of the milk. Research in the past decade has indicated that since 1930 or so in England and Wales the content of solids-not-fat in milk, and therefore the nutritive value of the milk, has tended to decline slightly but significantly. For many herds the solids-not-fat content of the bulked milk has been maintained well above the presumptive legal limit of 8.5 per cent, but for an undesirably high proportion of herds it has frequently been below it.

These facts led in 1958 to the appointment by the Minister of Agriculture, Fisheries and Food, the Minister of Health and the Secretary of State for Scotland of an interdepartmental committee under the chairmanship of Dr. J. W. Cook to consider the composition of milk and to recommend any legislative or other changes that might seem desirable. The Committee's report has now been published*. Various members of the Committee formed three panels, which considered medical and animal husbandry aspects, and the freezing-point (Hortvet) test for detecting the presence of added water in milk. The

reports of all three panels are published with the main report.

The Committee points out that great progress has been made in past years in improving the hygienic quality of milk; its members rightly believe that similar progress should now be made in improving its nutritive quality. To that end they have put forward some twenty-three main recommendations. They suggest, among other things, that the presumptive minimum legal standard of 8.5 per cent for the solids-not-fat content of milk should be abolished and that price penalties should ultimately be imposed when milk contains 8.4 per cent and less. They recommend also that milk-recording associations should provide means for testing the milk of individual cows for solids-not-fat as well as for fat.

There will certainly be many problems to solve before all the main recommendations made in the report can be implemented, and some breed societies and other bodies concerned will feel that the recommendations go much too far, while others will inevitably think that they do not go far enough. However that may be, it is clear that the Committee has done a very thorough job and that the adoption of its recommendations should have the desired effect of arresting and even reversing any tendency there may be for the nutritional quality of milk in the United Kingdom to decline. The report contains a wealth of information on the subject of the composition of milk and will long remain a most valuable and reliable work of reference on that subject.

A THEORY OF THE MECHANISM OF ACTION OF CREATINE PHOSPHOKINASE

By DA. B. R. RABIN and D. C. WATTS

Department of Biochemistry, University College, London

AS part of a programme of investigations on the evolution of biological catalysts, extensive work has been carried out in this Department on the mechanism of action of creatine phosphokinase from rabbit muscle. This enzyme catalyses the reaction:

It has been shown that the rate of formation of creatine phosphate (forward reaction) is maximal at pH 8.8-9.0, whereas the pH optimum for the formation of adenosine triphosphate (reverse reaction) is 6.0-7.0, depending on the buffers used. The enzyme requires the presence of magnesium(II) or manganese(II) ions, and it has been suggested¹ that a metal adenosine tri- or di-phosphate complex is the active substrate for the enzyme. Dixon² has stated, without giving any evidence, that there is reason for believing that the enzyme-substrate combination involves the formation of a thiol-magnesium phosphate complex. The available evidence favours neither of these hypotheses³.

Creatine phosphokinase has two reactive thiol groups per mole⁴, and alkylation of these with iodoacetate or iodoacetamide, destroys the enzyme activity. The kinetics of this reaction have been studied by measuring both the loss of enzyme activity and the production of iodide ions (using a silver/silver iodide electrode). These investigations have shown that only one of the SH groups is associated with the enzyme activity.

The reaction of the enzyme with iodoacetate and iodoacetamide as a function of pH is shown in Fig. 1. It can be seen that, over the pH range studied, the

reaction-rate is independent of pH. This surprising finding is explicable if both thiols are hydrogen-bonded to other groups. The effects of various components of the substrate system on the rate of alkylation of the thiol groups are shown in Table 1. The results were obtained by following the production of iodide ions, which measures the reaction of both thiol groups. Since only the thiol group at the active site is affected by modifiers, and the two thiol groups react at nearly the same rate (unpublished work from this Department), the kinetic effects on the active site are approximately twice those shown in Table 1. The significant effects have been confirmed by following the loss of activity. The simultaneous presence of all substrates and magnesium(II) causes considerable protection of the enzyme against reaction with both iodoacetate and iodoacetamide; in the absence of the metal, there is no significant protection.

Table 1. EFFECTS OF SUBSTRATES ON THE INITIAL RATE OF ALKYLATION OF CREATINE PHOSPHOKINASE AT 25° C. IN BORATE BUFFER pH 9.0 AT IONIC STRENGTH 0.12

Substrate added	Relative initial rate of iodide production (rate in absence of added substrate = 1.0)	
	Iodoacetate	Iodoacetamide
Nil	1.00	1.00
Equilibrium mixture + Mg(II)*	0.85	0.66
Equilibrium mixture†	0.91	1.05
Mg(II) (0.001 M)	1.01	0.97
ATP (0.001 M)	0.96	1.00
ATP (0.001 M) + Mg(II) (0.001 M)	0.81	1.00
ATP (0.001 M) + Cr (0.01 M)	0.96	1.07
Cr (0.01 M)	1.03	1.07
Cr (0.01 M) + Mg(II) (0.001 M)	1.01	0.98
ADP (0.001 M)	1.00	1.00
ADP (0.001 M) + Mg(II) (0.001 M)	1.27	1.01

* Obtained by allowing 0.001 M adenosine triphosphate (ATP), 0.01 M creatine and 0.001 M magnesium(II) to proceed to equilibrium before adding the alkylating agent.

† Approximate only. Consisted of the following mixture: adenosine di- and tri-phosphate, 0.0005 M; creatine phosphate, 0.0007 M creatine, 0.005 M.

Fig. 1. Effect of pH on the rate of alkylation of creatine phosphokinase. The reagent and protein concentrations were, respectively: for iodoacetate, 0.0005 M and 0.42 mgm./ml.; for iodoacetamide, 0.0001 M and 0.4 mgm./ml. Buffers: □, ■, diethylmalonic acid/sodium hydroxide; ▲, tri-(hydroxymethyl)aminomethane; ○, ●, boric acid/sodium hydroxide. Temperature, 25° C.; ionic strength, 0.12

The effects of ionic strength on the reaction of the enzyme with iodoacetate and iodoacetamide are shown in Fig. 2. The decrease in reaction-rate with increasing ionic strength observed with iodoacetate could be due to an electrostatic interaction between the carboxyl group and a positive locus on the enzyme. Thus it is evident that the effects of the various substrate components on the reaction of the protein with iodoacetate will be difficult to interpret because of this complication.

The failure of the metal ion, alone or in the presence of some of the substrate components, to protect the thiol group at the active site against alkylation argues against the metal being bound to the thiol.

Fig. 2. Effect of ionic strength on the rate of alkylation of creatine phosphokinase. The reagent and protein concentrations were, respectively: for Iodoacetate, 0.0005 *M* and 0.57 mgm./ml.; for Iodoacetamide, 0.0001 *M* and 0.4 mgm./ml. Temperature, 25° C.; pH 9.0 (boric acid/sodium hydroxide)

The high degree of specificity possessed by the enzyme for both guanine and purine components¹ indicates that these groups are bound at specific sites on the protein. If it is assumed that the thiol at the active site is hydrogen-bonded, perhaps to an imidazole residue, it is possible to visualize a mechanism for this enzyme which fits most of the data. The hydrogen-bonded thiol-imidazole system can be represented by Fig. 3. We suggest that interaction of the guanidine group with the thiol occurs only when both substrates and the metal are simultaneously present. The forward reaction can be represented by Fig. 4. In this the dashed lines are the bonds being formed or broken. The reaction proceeds by a synchronous set of bond re-arrangements, the rate-limiting step in which would be the simultaneous rupture and formation of the O—P and N—P bonds. The hydrogen-bond re-arrangements should occur with much greater facility than the nucleophilic displacement process at the phosphorus atom.

Fig. 3

The function of the metal in the forward process is to orientate the phosphate groups and assist the reaction by partial neutralization of the charges on the phosphate oxygen atoms. If the electronic tendencies shown in Fig. 4 are taken to completion, the species indicated in Fig. 5 are obtained. At high pH values a proton will ionize from adenosine diphosphate, probably while this is still attached to the enzyme surface, driving the reaction in the forward direction. Tautomeric re-arrangement, independent of pH, regenerating the thiol-imidazole hydrogen bond system shown in Fig. 3, would occur prior to dissociation of the substrates from the enzyme surface. The formation of adenosine triphosphate

Fig. 4

Fig. 5

would occur by complete reversal of the pathway of the forward reaction. Addition of a proton to enzyme-bound adenosine diphosphate is needed to trigger the reverse reaction, and this accounts for the lower pH optimum of the reverse process. The reverse reaction can be visualized as proceeding via the enzyme-substrate complex indicated in Fig. 6. Several tautomeric variants of this formulation are possible. A prototropic re-arrangement of thiol-imidazole would give the intermediate shown in Fig. 4 and the reaction would proceed by a counter-clockwise set of bond-shifts, the reversal of those in Fig. 4. The function of the metal in the formation of adenosine triphosphate is to hold the attacking phosphate of adenosine diphosphate near the phosphorus atom of creatine phosphate and assist the nucleophilic displacement at this atom by partial neutralization of the charges on the oxygen atoms.

It can be shown, by the use of models, that the proposed mechanism is stereochemically feasible. We have shown in the diagrams interaction of the sulphur with the guanidino group and interaction of

Fig. 6

the imidazole with a phosphate oxygen. It is, of course, possible that these sites of interaction are reversed without affecting the essential basis of the mechanism. This reaction is an interesting illustration of the principle of conjugate requirements²; in this instance the acid/base groups on the protein surface involved with attacking and departing groups are hydrogen-bonded together.

The mechanism we propose can easily be extended to other phosphokinases, and it is hoped that it will act as a guide and stimulus to further work on phosphate transfer systems.

We are indebted to the Central Research Fund, University of London, for a grant for the purchase of the automatic titration equipment used in these experiments. One of us (D. C. W.) thanks the Agricultural Research Council for a personal grant.

A POSSIBLE SPECIFIC CHROMOSOME ABNORMALITY IN HUMAN CHRONIC MYELOID LEUKÆMIA

By A. G. BAIKIE, W. M. COURT-BROWN, KARIN E. BUCKTON, D. G. HARNDEN, PATRICIA A. JACOBS and ISHBEL M. TOUGH

Medical Research Council Clinical Effects of Radiation Research Unit, Western General Hospital, Crewe Road, Edinburgh, 4

THREE reports have been published which indicate that in some cases of acute leukaemia in man there are abnormalities of both number and morphology of the chromosomes in the leukaemic cells¹⁻³. However, no consistent abnormality has yet been found which can be linked to a specific cytological type of acute leukaemia. Baikie *et al.*² also reported that they were unable to detect any chromosome abnormality in bone marrow preparations from a number of cases of chronic myeloid and chronic lymphatic leukaemia. Nevertheless, it was said at the time that the standard of the preparations was such that the possibility of a small chromosomal lesion could not be excluded.

In recent months considerable developments have occurred as a result of the utilization of the technique of Hungerford *et al.*⁴ for the culture of the leucocyte component of the peripheral blood. It is now recognized that chromosome preparations made from such cultures are of an appreciably better quality than those made from bone marrow. Using this blood culture technique, Nowell and Hungerford⁵ noted the presence of a minute chromosome in dividing cells from the peripheral blood of two male patients with chronic myeloid leukaemia, and they regarded this as an unusually small Y chromosome. At about the same time as these observations were published, we noted the presence, in blood culture preparations, of a similar small chromosome in two female patients with chronic myeloid leukaemia. It was apparent, therefore, that if the same abnormal chromosome was being viewed by both groups of workers, then the abnormality must involve an autosome and not the Y chromosome. In the light of these findings we re-examined all our material from cases of chronic myeloid leukaemia, as well as studying two fresh cases of the disease. As a result of this we are satisfied that the presence of an unusually small autosome (Fig. 1) is a characteristic feature of many cases of chronic myeloid leukaemia.

Altogether we have studied the chromosomes in blood cultures from 12 patients (4 males and 8 females) suffering from chronic myeloid leukaemia. Among these were two patients who had had no previous

treatment for their disease, either by X-irradiation or by chemotherapy. The remaining 10 patients had all been treated by radiotherapy some time prior to our work. The small chromosome was noted in preparations from eight patients, inclusive of both the untreated patients. Included among the 12 patients were three in a terminal acute transformation of the disease, and the relevant chromosome was noted in cultures from one of these. Marrow preparations have been studied from 10 patients, of whom four were males, and the small chromosome has been clearly seen in three patients, all three being fresh untreated cases. These three latter patients include two of those in whom the chromosome was also seen in blood culture. The remaining seven marrow preparations were of too poor a quality for us to be

Fig. 1. Cell from the leucocyte component of blood cultured from a female with chronic myeloid leukaemia. The three normal-sized small acrocentric chromosomes are marked A. The unusually small acrocentric is marked B.

certain as to whether the abnormality was present or not. In no case has the abnormally small chromosome been seen in every cell. The frequency of its occurrence has varied from 1/7 cells to 48/50 cells studied, and in all patients some normal euploid cells have been seen.

In addition to re-examining our material from cases of chronic myeloid leukaemia, we have also re-examined our preparations from the peripheral blood of individuals with apparently normal karyotypes, and our marrow and blood preparations from patients with acute leukaemia in which we had thought no chromosome abnormality to be present. Blood preparations were available from 90 individuals with apparently normal karyotypes and seven were selected at random, to which were added five preparations from cases of chronic myeloid leukaemia showing the small chromosome. These twelve preparations were then submitted to an independent observer who was ignorant of the patients involved. The five preparations with the small chromosome were readily identified, and in none of the seven control preparations was the chromosome thought to be present. We have also reviewed marrow preparations from eleven patients and blood preparations from six patients with acute leukaemia having an apparently normal karyotype, and we have no evidence in these of the unusually small chromosome. Finally, we have studied the blood cultures from five cases of mongolism associated with acute leukaemia and found no abnormality apart for the classical mongol karyotype which is presumed to be trisomy for autosome 21.

Before discussing the possible significance of these findings, the question of radiation exposure has to be considered, as chronic myeloid leukaemia is increased in frequency in heavily irradiated populations^{6,7}. We have not been able to check with any certainty the histories of diagnostic X-ray exposure of our patients prior to the development of their leukaemic state. Two patients, however, have histories of radiotherapeutic exposure for conditions quite unrelated to leukaemia. One patient, a woman, was treated in December 1953, for a simple papilloma of the bladder by means of a radium implant. An area 3 x 3 cm. on the base of the bladder was given a dose of 6,000 rads over a period of 146 hr. This patient was diagnosed as having chronic myeloid leukaemia in May 1958, and the unusually small chromosome has been identified in cultured blood cells. The second patient, a male, was treated for ankylosing spondylitis between February and April 1955, a total dose of 1,500 rads being given to the skin over the whole length of the spine and the sacroiliac joints. A diagnosis of chronic myeloid leukaemia was made in March 1956. Only marrow cultures were available from this man and their quality was such that we could not be certain whether the small chromosome was present or not. On the basis of our knowledge of the distribution of the latent periods of radiation-induced leukaemias between radiation exposure and diagnosis, we cannot exclude the possibility that the first case was induced by radiation; it seems, however, unlikely that this was so in the second case, as the length of the latent period following a single heavy exposure usually lies between four and eight years, and the increased frequency of leukaemia is not noted until the second post-exposure year.

It now seems certain that the unusually small chromosome is one of the members of the two

pairs of small acrocentric chromosomes numbered 21 and 22 in the Denver Classification. The most reasonable explanation for its small size is the occurrence of a deletion. The fact that we have in every preparation found some normal euploid cells suggests that the error does not occur in all the body cells and presumably is confined to cells from the bone marrow. We are at present undertaking the investigation of the chromosomes from skin culture preparations to help to clarify this point*. We have not noted the unusually small chromosome in any other person that we have studied. Carter *et al.*⁸, however, have published ideograms of the chromosomes from blood cultures made from a mother and her mongol son, and in both these ideograms an unusually small chromosome appears to be present. The mother has a diploid number of 45, and is considered to have a translocation involving autosomes numbers 15 and 21, while the son has the full complement of small acrocentrics in addition to the same translocation, and is presumed to be effectively trisomic for number 21.

It has been established that mongols have a heightened probability of developing acute leukaemia⁹⁻¹³, but not apparently of developing chronic myeloid leukaemia. From unpublished observations on death certificate data (Court-Brown and Doll) it does not appear that this increased liability relates to any specific cytological type of acute leukaemia, although the unreliability of such data must be borne in mind. It is also known that in most mongols there is a morphological abnormality of the polymorphonuclear leucocytes which takes the form of a deficiency in nuclear lobulation¹⁴. It is not unreasonable, therefore, to suggest that the autosome involved in mongolism may possess a locus or loci concerned with some aspect of the control of leucopoiesis. Our present findings in relation to chronic myeloid leukaemia indicate that in many cases of this disease there appears to be a deletion involving either autosome 21 or 22. In the meantime it would seem not unreasonable to adopt the working hypothesis that the same autosome is involved in many cases of chronic myeloid leukaemia and in mongolism.

*Note added in proof. Since this communication was submitted for publication, it has been possible to examine the chromosomes in cells from skin cultures of three patients with chronic myeloid leukaemia. Blood culture studies of all three patients showed the presence of the unusually small chromosome, but this was not seen in any of the skin cells.

BLUE WILDEBEEST AND THE AETIOLOGICAL AGENT OF BOVINE MALIGNANT CATARRHAL FEVER

By W. PLOWRIGHT, R. D. FERRIS and G. R. SCOTT

East African Veterinary Research Organization, Muguga, P.O. Box 32, Kikuyu, Kenya

MALIGNANT catarrhal fever of cattle is a transmissible disease of world-wide distribution, sporadic occurrence and very high mortality¹⁻³; it is not contagious^{1,2,4} and fomites are not infectious on parenteral inoculation¹. The aetiological agent is generally held to be a virus although, to our knowledge, there has been no reliable proof of its filterability.

In the majority of countries it is believed, largely on circumstantial evidence, that sheep are reservoirs of the virus without ever showing any clinical signs of its presence^{5,6-8}. However, the mode of transmission from sheep to cattle has not been determined, and, in fact, the full clinical and pathological syndrome has never been reproduced in cattle by inoculation of materials from sheep. In Africa, infections among cattle often follow close association with apparently normal wildebeest^{1,7,9,10}, but the only experimental proof that the latter may harbour the agent of malignant catarrhal fever was provided by Mettam¹. In one instance he inoculated the blood of a black wildebeest (*Connochaetes gnou*, Zimmerman) into an ox which showed a transitory pyrexia 14 days later. Blood collected at this time caused typical malignant catarrhal fever on sub-inoculation to another ox. Further attempts to demonstrate the virus in wildebeest consistently failed.

We have recently investigated the role of the blue wildebeest (*Gorgon taurinus taurinus*, Burchell) in the epizootiology of malignant catarrhal fever in Kenya. The causal agent has been isolated from them and successfully propagated in cattle, rabbits and monolayer tissue cultures; the latter, especially, have thrown new light on its salient characteristics, which are here described in a preliminary manner.

During February 1959 and February-March 1960, 35 blue wildebeest of varying age and sex (Table 1) were shot in two game reserves of Kenya which are about 100 miles distant from each other. Heparinized blood and, occasionally, spleen and lymph-node tissue were collected immediately, stored on ice and within 48 hr. inoculated into cattle by the intravenous or subcutaneous routes. Monolayers were prepared from trypsinized cells derived from five near-term foetuses and four calves 1-3 months old; all these cultures were observed for 28 days to detect cytopathic changes. Finally, leucocyte fractions from about 200 ml. of blood of 20 wildebeest were inoculated into monolayer cultures of normal bovine thyroid cells (*vide infra*) and suspensions of two foetal spleens were used for cattle and culture inoculations.

Five isolates of malignant catarrhal fever virus were recovered from the 35 wildebeest, three from females in late pregnancy, one each from a yearling male and a yearling female (Table 1). Animal

Table 1. ISOLATION OF MALIGNANT CATARRHAL FEVER VIRUS FROM BLUE WILDEBEEST IN KENYA

Age	Sex	No. of animals	No. positive on cattle inoculation*	No. positive by all tissue culture tests	Remarks
Mature† Pregnant	F	8	3/8	0/8	One isolate recovered from foetal spleen only
Mature Yearling	F	4	0/4	0/3	First cytopathic changes, day 16
	F	6	0/6	1/6	
< 3 months	F	2	0/2	0/2	First cytopathic changes, day 18
Mature† Yearling	M	7	0/7	0/5	
	M	6	0/6	1/3	
< 3 months	M	2	0/2	0/2	
Totals	—	—	3/35	2/29	5 isolates recovered from 35 wildebeest

* Blood was inoculated in a dose of 25 to 200 ml., tissue suspensions contained 3-10 gm. material.

† Mature means estimated to be two years or older.

inoculations yielded three isolates, bovine thyroid cultures two different strains, one of which was shown to produce typical malignant catarrhal fever in cattle. No infective virus was demonstrated in lightly centrifuged suspensions of pooled spleen and lymph node tissue from the two pregnant animals which were proved to have had a viraemia.

The disease developed in cattle after an initial incubation period of 34-38 days, being clinically identical in all respects to the virulent 'head-and-eye' form¹¹. Pathological and haematological changes in infected cattle were similar to those described previously for cattle-derived strains of this virus¹⁰⁻¹². In addition to the well-known perivascular accumulations of mononuclear cells, there was an angiitis of both arteries and veins characterized by necrosis and mononuclear cell infiltration of the media with swelling and proliferation of the endothelium¹².

One isolate was carried by two methods through more than 20 serial passages in cattle. The first line was maintained by the intravenous inoculation of heparinized blood, 5 ml. being an effective dose; for the second, crude 10 per cent suspensions were prepared in Ten Broeck grinders from preapular lymph-node tissue and 5 ml. quantities of these were inoculated subcutaneously. Once established in cattle the incubation period decreased to a mean 18.5 ± 1.1 days, and the method of sub-inoculation did not

produce significant variations in this parameter. The mortality was 96 per cent with an average survival time of 8.7 ± 0.8 days.

Ten per cent lymph-node suspensions of the third to twenty-fourth passages produced the disease in cattle after 10^{-2} – 10^{-3} dilution. Nevertheless, the supernatants remaining after centrifugation for 10 min. at 2,000 r.p.m. were devoid of infectivity in a dose of 20–25 ml. Similarly, 100 ml. of plasma was non-infective although whole blood had a titre of 10^{-1} – 10^{-2} per 5 ml. These observations confirmed and extended previous findings^{13,14}.

The agent was established in rabbits¹⁰ by the intracerebral or intraperitoneal inoculation of cattle lymph-node tissue and passaged by the intracerebral inoculation of brain or the intraperitoneal injection of spleen or lymph-node suspensions. The average incubation period in this species was 15.2 ± 0.8 days, death following invariably and usually suddenly after a further 4.6 ± 1.3 days. The post-mortem findings and histopathology were similar to those already described^{10,12}. Plasma or low-speed supernatants from suspensions of infected tissues sometimes contained infective virus, thus differing from cattle materials treated similarly.

Initial attempts to propagate the virus in tissue culture were made by preparing monolayers from the kidneys, bone marrow and blood leucocytes of infected cattle. No cytopathogenic effect was observed at this time in living or stained cultures during an observation period of 28–30 days. Lymph-node suspensions produced no specific changes in established primary cultures of calf or sheep embryonic kidney and calf or sheep testis. Stimulated by the work of Pulvertaft¹⁵, we then prepared monolayers from trypsin-dispersed cells of the thyroid of an infected ox, and these cultures showed a focal cytopathogenic effect first observed on the ninth day. The causal agent could not be passaged with cell-free fluids from the infected culture, but subcultivation to other thyroid monolayers was achieved by intact cells removed from the glass mechanically or with a mixture of versene and trypsin. These cell suspensions also reproduced malignant catarrhal fever in cattle following intravenous administration. Stained cover-slip preparations showed that the cytopathic changes observed were characterized by the formation of syncytia with intranuclear inclusions of type A (Fig. 1).

Similar cytopathogenic agents were regularly recovered by culture of the thyroid glands of other diseased cattle, infected with the same and other wildebeest isolates. The incubation period, when cell growth was satisfactory, was about 6–8 days. Furthermore, it was found that monolayers were readily prepared from adrenal gland tissue of infected cattle, and that these showed identical focal cytopathic changes, frequently detectable after 5–9 days. Virus of similar cytopathogenicity was also demonstrated in the blood of infected wildebeest (Table 1), cattle and rabbits and in lymph-node suspensions from the last two, by inoculation on to normal calf thyroid monolayers. Cytopathic changes were seen after as little as 3–4 days in the case of the last two species, blood titres reaching $10^{3.2}$ TCD₅₀ per ml. and gland titres $10^{4.4}$ TCD₅₀ per gm. in the ox. No cytopathogenic agent was ever recovered from uninoculated control cultures observed over prolonged periods.

Cell types which were found to be susceptible to the virus isolated in thyroid cultures included primary

Fig. 1. Thyroid monolayer from an infected ox, eight days after seeding, showing a nuclear aggregation with intranuclear inclusions.

sheep thyroid, calf testis and adrenal or rabbit and wildebeest kidney. In all these, however, as also in bovine thyroid, there was a tendency for the virus-induced changes to become progressively less extensive on passage or prolonged cultivation. Very satisfactory serial cultivation was eventually achieved by employing an 'established' line of calf kidney cells developed in this laboratory by one of us (R. D. F.). Suspensions were mixed, at the time of seeding into culture vessels, with infected trypsin-dispersed cells of the previous passage. Cytopathic foci then appeared after as little as 24 hr., often extending to involve a large proportion of the available cells in 5–7 days.

Five isolates were passed 14–38 times in this manner, the total period of time in culture varying from 3 to 10 months. Full cattle pathogenicity was retained at least up to the tenth to nineteenth passages for three isolates tested. Trypsin-dispersed cells from infected cultures were titrated by mixing 10-fold dilutions in growth medium with 'clean' suspensions of the cell line. The maximum number of infective centres was approximately 10 per cent of the total viable units as estimated by single cell counts after staining with neutral red. A suspension containing $10^{4.9}$ TCD₅₀ per ml. of fourteenth culture passage virus had a cattle infective titre of $10^{3.2}$.

For a variable period no virus could be demonstrated in cell-free fluids from infected cultures, but after seven to thirty passages it was found that all four isolates produced free virus. This was not deposited at 5,000g for 30 min. and reached a titre of $10^{3.3}$ TCD₅₀ per ml. in one instance. Free virus was shown to be capable of passing graded collodion membranes of average pore diameter 430 mμ.

The cause of malignant catarrhal fever is therefore a virus which is present in the tissues of a proportion of apparently normal wildebeest in two widely separated areas of Kenya. The recovery of the virus from the spleen of a wildebeest foetus *in utero* (Table 1) showed that trans-placental transmission occurs in this species. It can be propagated in suitable monolayer tissue cultures and produces a cytopathology which resembles that of herpes simplex¹⁶, B virus¹⁷, pseudorabies¹⁸, varicella and herpes zoster¹⁹. It is remarkable that the histopathology of malignant catarrhal fever in cattle and rabbits has never been

reported to include either the formation of syncytia or the presence of intranuclear inclusions. A careful re-examination of material available to one of us (W. P.) has confirmed the absence of both these features.

Epizootologically malignant catarrhal fever virus behaves like B virus, herpes simplex and pseudorabies in that these agents usually cause very mild infections in their customary reservoirs (monkey, man and pig, respectively) but highly fatal diseases when introduced into other experimental or natural hosts^{10,11}. Herpes is a classic example of persistent infection, and some authorities^{12,13} consider that herpes zoster may be a manifestation of recurrent pathogenic activity in individuals harbouring the virus of varicella. A viraemia extending over many months has been proved in this laboratory to be present in some of the few cattle which recover from malignant catarrhal fever. It is probable that the same virus persists for long periods, if not for life, in sheep and wildebeest.

The agent of malignant catarrhal fever resembles varicella and herpes zoster in its failure to produce free virus in early culture passages¹⁴, but differs from them in that all tested isolates do so later and that cell-free virus cannot be demonstrated in the tissues of infected cattle. This last is a most important fact, which probably explains many failures to transmit the disease experimentally and also to filter and conserve the causal agent. In connexion with the last problem it may be noted that methods employed for the preservation of cell lines at low temperatures have been shown by us to be suitable for the long-term storage of the agent in cultured cells. The absence of free virus in cattle has an obvious bearing on the technique and interpretation of quantitative studies on the multiplication and distribution of the virus in tissues of infected animals. It is also fundamental to a study of its resistance to various physical and chemical agents, or neutralization by 'immune' sera.

The peculiar sensitivity of thyroid and, to a less extent, adrenal cells for the primary isolation of malignant catarrhal fever virus and the failure of other more widely employed types suggests that the former may possibly be used with advantage for other viruses which have so far failed to produce cytopathogenic effects *in vitro*.

More detailed results of these and other investigations will be published elsewhere.

We are grateful to Capt. D. N. Zaphiro, Kenya Game Department, and to Lee M. Talbot, Wildlife Research Project, U.S. National Academy of Sciences, for invaluable help in the collection of tissues from wildebeest.

ROLE OF CEREAL FAT IN THE PRODUCTION OF NUTRITIONAL DISEASE IN PIGS

By B. THAFVELIN

State Veterinary Institute, Stockholm

IN Sweden nutritional diseases such as hepatitis diabetica (dietetic liver necrosis) and muscular degeneration represent a serious hazard in pig raising. Through pathological and experimental work, Obel¹ demonstrated that two factors—vitamin E and the sulphur-containing amino-acids, methionine and cystine—are effective in preventing hepatitis diabetica and suggested that Schwarz's factor 3 might also be involved. Since Schwarz and Foltz² detected the factor 3 effect of selenium compounds, and Eggert *et al.*³ and Grant and Thafvelin⁴ have shown the effectiveness of selenium salts for the prevention of experimental hepatitis in pigs, and since Schwarz *et al.*⁵ have established that the protective effect of the sulphur-containing amino-acids almost certainly depends on contamination with selenium, attention is now mainly directed towards

vitamin E and factor 3 (that is, biologically active selenium) in the aetiology of the lesions concerned. The absolute vitamin E content of feeds is *per se* of interest; but it is the relationship between the amounts of vitamin E and polyunsaturated fatty acids which seems to deserve emphasis. For this reason the unsaturated fatty acids of cereal grains have assumed a central place in current work on hepatitis diabetica and muscular dystrophy in pigs.

In spite of conventional prophylaxis through dietary manipulation (cod liver oil is nowadays fed only sparingly to pigs), too many cases of hepatitis diabetica and muscular degeneration occur among pigs in Sweden. There is reason to look into the aetiological importance of the grain fed since these diseases often occur among pigs fed nearly exclusively on grain.

Table 1. PROPERTIES OF THE VARIOUS FEEDS

Feed	Fat content (per cent)	Iodine No.	Free fatty acids ml. KOH/gm. fat	Peroxide value m.equiv./kgm. fat	Tocopherol content (α -tocopherol) mgm./100 gm.
Feed I, unheated	4.8	78	77	0	2.36
Feed I, heated	3.7	37	53	140*	0.43
Feed II, unheated	3.8	75	135	164	0.40
Feed II, heated	2.7	70	130	0	0.87
Malze oil, fresh	—	112	1.2	0	69.9
Malze oil, heated	—	109	1.4	250*	6.31

* Mean throughout experiment.

Theoretically, there are two aspects of the disease-producing properties of feed grains to be considered—the unsaturated fatty acids and the level of biologically active selenium. In a recent paper⁴, we have published the results of work on cereal fats and have indicated their potentialities for becoming rancid in certain circumstances. This article gives a brief account of attempts to produce nutritional lesions in pigs by feeding grain containing rancid fats or fats with a tendency towards autoxidation. The results were checked by feeding pure vegetable oil of known oxidative status.

Apart from the experimental feeds to be described here, the pigs received daily supplements of 1–1.5 litres skimmed milk and minerals. Pigs of the Swedish Landras breed, 10–12 weeks old, were used. Routine blood analyses and determinations of serum transaminase activities (glutamic-oxalacetic transaminase (GOT) according to Karmen-Ordell⁷) were performed. Our normal value for serum-GOT activity in pigs is 22.5 ± 7.7 ($n = 61$) Karmen-Ordell units. Through work on pigs of the same breed carried out by Reitman and Frankel's method, a normal value for serum-GOT activity of 28.03 ± 15.39 units was found by Wretling, Orstadius and Lindberg⁸.

'Peroxide'-levels in the cereal fat and vegetable oil were estimated by a method developed by K. Erne of this Institute.

The tocopherol contents were determined in the laboratories of AB Ewos, Sodertälje, by Dr. G. Ekstrom using the method of F. Bro-Rasmussen and W. Hjarde⁹. All pigs which died or were killed were autopsied (C. A. Grant⁴). The lesions of hepatosis diabetica and muscular degeneration were evaluated by conventional standards¹. The criteria applied for the diagnosis 'plotzlicher Herztod' have been briefly mentioned before⁴ and will be presented more fully in another connexion.

Experiment 1. The effect of feeding grain containing fats of great susceptibility towards rancidity (feed I).

As shown in Table 1, autoxidation could be induced in this sample of grain by heating in an incubator (21 hr. at 100° C.). Five pigs received grain heated in this manner and five received unheated grain from the same sample. Significantly increased serum-GOT values were recorded for the first group from the twenty-first day (Fig. 1). Two died after 21 and 33 days, respectively, and the remaining three were killed after 56 days. The major autopsy findings are given in Table 2.

The five control pigs remained clinically healthy. All were killed on the thirty-sixth day. From the transaminase values given in Fig. 2 and from experience with previous experiments it appears most likely that tissue destruction did not occur during the experimental period. On several occasions during the last days of the experiment the pigs fought savagely;

this experiment is to be repeated with precautions to eliminate fighting.

Experiment 2. The effect of feeding grain containing fat which had spontaneously oxidized during storage (feed II).

This sample of grain had produced nutritional lesions among pigs on a farm. Five pigs were given the feed as such. Five control animals received the grain heated in an incubator at 100° C. for 4 hr. at the beginning of the experiment and later for 6 hr. to accelerate the oxidative processes to stability (Table 1). Increased serum-GOT values were seen in the pigs of the first group by the sixth day (Fig. 3). One pig died on the thirteenth day, two on the fourteenth, and the remaining two were killed on the thirty-eighth and fortieth days, respectively.

Fig. 1. Serum enzyme-levels for pigs fed grain heated in order to induce oxidation

Fig. 2. Serum enzyme-levels for pigs fed unheated grain

Table 2. MAJOR AUTOPSY FINDINGS

Group	No. of animals	Lesions of 'plotzlicher Herztod'	Waxy degeneration of skeletal muscles	Hepatosi diaetetica
Feed I, unheated†	5			
Feed I, heated	5	4	5 + + + *	0
Feed II, unheated	5	5	5 + + +	1
Feed II, heated	5	0	5 + to + +	0
Maize oil, fresh	2	0	1 (+)	0
Maize oil, heated	2	2	2 + + +	1

Degree of degeneration:

* (+), only a few fibres involved; +, slight degeneration; ++, moderate degeneration; + + +, pronounced degeneration.

† See text under experiment 1.

No clinical signs were seen in the five control pigs although all showed slightly increased serum-GOT activities (Fig. 4).

The major autopsy findings are given in Table 2.

Experiment 3. The effects of feeding fresh and rancid vegetable oil.

As a pilot experiment four pigs were fed a normal diet to which was added a daily supplement of 250 ml maize oil per pig. Two pigs received fresh oil and two oil which had been oxidized by heating (Table 1).

The pigs fed rancid maize oil died after 16 and 37 days respectively. Serum-GOT values were elevated throughout the course of the experiment (Fig. 5).

No clinical signs and no increase in serum-GOT activities were evident for the two control animals (Fig. 6).

The major autopsy findings are listed in Table 2.

Discussion

It has long been known that hepatosis diaetetica, muscular dystrophy and allied lesions can be produced experimentally by feeds which contain unsaturated fatty acids of marine origin^{1,10-14}. It is, however, an observed fact that the addition of marine fat to pig feed is by no means a prerequisite for the occurrence of these lesions in Swedish pigs. Grain, on the other hand, forms the greater part of conventional pig rations. With this in mind, the question could be posed whether or not the natural fat of the grain could in certain circumstances be the underlying cause of these disorders. Chemical studies of the properties of cereal fat during various phases of maturation and under various storage conditions have shown this hypothesis to be theoretically accept-

able¹⁵⁻¹⁷. The results of this initial work can be summarized as follows.

(1) 'New grain' contains fats characterized by little or no rancidity but also by great susceptibility to rancidity. This susceptibility steadily decreases during storage.

(2) If ground, grain will gradually lose the ability to protect its fat against oxidation and, depending on its original properties, sooner or later during storage in this state will become rancid.

Expressed in another way, grain can in certain circumstances contain unstable fats, that is, fats with a tendency to become rancid. This is especially apparent during rainy years with little sunshine. In experiment 1, grain of this type was ground and heated to give it roughly the same properties as ground grain stored under natural conditions. Treated in this way, the grain produced the lesions listed in Table 2.

The grain fed in experiment 2 was known to have produced spontaneous disease in a herd of pigs. The grain as such contained highly oxidized fats and produced the lesions described in Table 2. Through heating, it was possible to stabilize the fat and in that way greatly reduce its disease-producing propensity.

Finally, it could be shown in experiment 3 that pure vegetable oil, when oxidized, can produce lesions belonging to the same group as those encountered in the other two experiments and in pigs dying of the spontaneous diseases.

To sum up, then, there is ample evidence suggesting that when hepatosis diaetetica, muscular degeneration and allied disorders are seen in pigs fed mainly on grain, the occurrence of these lesions can be coupled with the properties of the cereal fat.

These investigations have been supported by grants from Jordbrukets forskningsråd. GOT reagents have kindly been supplied by AB Kabi, Stockholm.

THE BIOSPECIES IN ENTOMOLOGY

By M. F. CLARIDGE

Department of Zoology, University College, Cardiff

AT a recent joint discussion of the Linnean Society and the Systematics Association on the subject of the sub-species, it was quite evident that there is still no basic agreement between biologists on the nature of the species itself. Thus there can be little hope of defining the sub-species to the satisfaction of all workers.

It has been argued recently^{1,2} that the term species should be restricted entirely to a morphological entity: that is, it would be the lowest taxonomic category (except the variety?) above the individual and be defined entirely morphologically. In considering sexually reproducing forms, the justification for such a concept is that it represents the nearest approach to a true biological species which can be attained in the present state of knowledge for many animal and plant groups. Even to Linnaeus the species was a biological entity characterized by a quality of breeding true³. Later workers stressed the importance of a sterility barrier between species. Poulton⁴ developed the idea of the species as a freely interbreeding series of populations in Nature and coined the term 'syngamy' for such a free-interbreeding relationship. Even at the beginning of this century Poulton⁴ was aware of the difficulty of determining the status of geographically isolated or allopatric forms, since it was not possible to determine whether or not such forms could interbreed in the field. This led to the modern polytypic species taking account of variation in space, that is, geographical

variation. The concept has been fully developed by Mayr⁵ and critically reviewed by Cain⁶. Unfortunately, the status of truly allopatric forms can never be determined with certainty. However, sympatric forms, that is those the breeding ranges of which either coincide or overlap in Nature, can be delimited objectively by the presence or absence of syngamy, of what Mayr⁵ has termed "crossability", between them. There is no biological reason why morphological differences should always be associated with the breeding barrier and thus no *a priori* reason why there should always be morphological differences between species. Of course there usually will be such differences which can then be used as indicators of the true biospecific limits. This is the main justification for the use of the morphospecies in neontology when considering bisexually reproducing forms.

Dobzhansky^{7,8} has developed the theory of speciation by spatial isolation of populations and subsequent selection for isolating mechanisms. It is supposed that the populations would diverge genetically when in spatial isolation due to the differential action of natural selection in the different environments. On meeting again, hybrids between the forms would be at a selective disadvantage to either of the parental types, and, providing that this disadvantage was large enough not to be swamped, there would be heavy selection for the establishment of isolating mechanisms and eventually separation as good species. Koopman⁹ has been able to demonstrate the very

rapid evolution of isolating mechanisms in the laboratory between two very closely allied species of *Drosophila*, *D. pseudoobscura* Frolova and *D. persimilis* Dobzhansky and Epling, which can be made to interbreed at temperatures of about 16° C. These experiments strongly support Dobzhansky's theory, which also seems adequate to explain the existence of many groups of insects in which morphological specific differences are either very small or almost non-existent. In such groups the species often differ more obviously in biological features.

It is essential that there should be some ecological differences between closely allied sympatric species if they are to co-exist. Ecological differences such as separate breeding seasons may have arisen when the populations were spatially isolated and would then automatically be important as isolating mechanisms when the populations met again. However, some ecological differences may not be of importance in the actual process of speciation, but only in the avoidance of competition after specific differentiation. Thus differences between closely allied sympatric species may be of at least two kinds, associated either with the primary isolating mechanisms or with secondary ecological differences and usually with both. However, morphological characteristics need not always be associated with either. Thus in my view it is wrong to insist on distinct morphological characters for separating species when the only certain criterion is the presence of reproductive isolation. Perhaps the most satisfactory definition of the biological species or biospecies is that of Mayr⁵, namely, "Species are groups of actually or potentially interbreeding natural populations, which are reproductively isolated from other such groups". The only weakness lies in the phrase "potentially interbreeding", which has to be introduced in order to include allopatric populations.

All grades of morphological differences between true biospecies have been recorded, including many in which the differences are very slight. Well-known examples of such sibling species are *Drosophila pseudoobscura* and *D. persimilis*¹⁰ and the species of the *Anopheles maculipennis* group¹¹. Undoubtedly many

further examples exist and will be uncovered during the course of intensive biological investigations which are now being carried out in many insect groups. Recently, Claridge and Askew¹² have described a group of siblings in the genus *Eurytoma* (Hym., Chalcidoidea). *E. rosae* Nees and *E. brunneiventris* Ratz. are inseparable on the adult characters which I have been able to study, but they differ in characters of the egg and in details of hosts and life-histories. Also in the family Eurytomidae, Neunzig and Gyrisco¹³ have recently shown that *Bruchophagus platypterus* (Walk.) (= *gibbus* Boh.) is an aggregate of at least three species with definite host plant preferences. There is also evidence of the widespread occurrence of sibling species in other groups of Chalcidoidea.

The desire to retain the species as a static morphological entity with little reference to biological reality must be overcome if taxonomy is to make further contributions to biological science. It may be, as suggested by Gilmour³, that the problems in botanical taxonomy are so great that a completely new system of categories is required. However, this would be a very unfortunate change since it would obscure the similarities between the real biological entities of both zoological and botanical taxonomy.

I thank Dr. A. J. Cain for discussion on the subject-matter of this article.

SOME OXIDATIVE AND HYDROXYLATIVE ACTIONS OF QUARTZ: THEIR POSSIBLE RELATIONSHIP TO THE DEVELOPMENT OF SILICOSIS

By L. W. MARASAS and DR. J. S. HARRINGTON

Pneumoconiosis Research Unit, South African Council for Scientific and Industrial Research, P.O. Box 1038, Johannesburg

THE existence of a special surface activity possessed by siliceous dusts and silicates has been frequently reported in the literature. Hauser¹ indicated that the formation of a free silica surface was accompanied by the liberation of protons and the formation of atomic oxygen, and found a correlation between particle size and amount of oxygen released. In essence, he postulated that the unusual oxidation potential of silica resulted from the decomposition of some superoxide ions to yield atomic oxygen. Weyl² considered a type of dynamic hydration-dehydration equilibrium which would account for the fact that

siliceous materials were able to act as oxidation catalysts in the presence of air.

Our interest was given stimulus when we found that quartz dust could be employed successfully as an oxidant in a number of *in vitro* oxidation reactions, and we have since verified some of the postulates set out above.

Since the conversion of proline to hydroxyproline can be readily effected by hydrogen peroxide, we have been able to estimate quantitatively the oxidative activity of a number of dusts of known particle size as 'peroxide equivalents' per unit weight per

unit time for this conversion. The peroxide equivalent of a dust is obtained by comparing the amount of hydroxyproline (colorimetrically at 560 m μ) which can be produced by 1 gm. of dust shaken with 5 mgm. of proline for 30 min., with that amount produced by 2.5 mgm. of hydrogen peroxide under the same conditions. Table 1 shows a list of dusts in decreasing order of activity; in addition to the dusts listed, 'Aerosil' (250–500 Å. 'colloidal silica') has since been shown qualitatively to hydroxylate proline.

On the face value a correlation appears to exist between the 'oxidative activity' of the dusts and the known fibrogenetic potential of the materials examined. Crocidolite, however, is an exception; there are a number of suggestions for its apparently anomalous behaviour and these are being investigated together with the behaviour of other silicates. A further connexion between particle size and activity also seems apparent in the case of coarse quartz and the other quartz dusts of a much smaller size. Whether there is any relationship between oxidation and surface area is at present being examined.

It has been shown in the laboratory (Table 2) that quartz can bring about a number of oxidative and hydroxylative conversions, many of which have been previously demonstrated in biological systems.

In all cases the products were identified by paper chromatography with specific detection reagents and by the use of pure standards, and wherever possible the identity of the products was checked by colorimetric estimation, followed by examination of the absorption spectra obtained.

Particularly interesting conversions which have been listed above are the hydroxylations of proline and lysine to yield small amounts of hydroxyproline and hydroxylysine, respectively, amino-acids found almost specifically in collagenous protein. In addition, glycine, another important amino-acid of collagen, has been shown to be produced by quartz.

The maximum yield of hydroxyproline obtained with quartz under optimum conditions was 0.1 and 0.16 per cent in the presence of vitamin C. In most cases the yield was improved by dry shaking instead of wet, and in the case of hydroxyproline, it was enhanced by the addition of certain co-factors, the most important of which was ascorbic acid; this increased the yield up to 60 per cent. The additional observation was made that ascorbic acid can feebly hydroxylate proline *in vitro*, and this raises the question whether quartz does not actually synergize the ascorbic acid hydroxylation of proline.

Table 1. OXIDATIVE ACTIVITY OF VARIOUS DUST SAMPLES IN TERMS OF THEIR ABILITY TO CONVERT PROLINE TO HYDROXYPROLINE

Sample*	Per cent size distribution (μ)	Peroxide equivalent (mgm.)
Superfine quartz dust	87 < 1	8.25
Acid-washed quartz dust	92 < 1	8.00
Mine dust (Witwatersrand gold mine)	84 < 1	2.70
Coarse quartz dust	90 > 5	1.75
Coal dust	86 < 1	1.00
Crocidolite	86 < 1	nil
Kaolin	92 < 1	nil
Talc	76 < 1	nil

* The materials used have the following characteristics: superfine quartz dust (0.08 mgm. iron/gm.) (Dowson and Dobson); acid-washed quartz (trace of iron present after washing with hydrochloric acid); mine dust (64 per cent silica) (Witwatersrand gold mine); coarse quartz dust (0.06 mgm. iron/gm.), prepared by sedimentation; coal dust: anthracite (8.6 per cent silica); crocidolite: blue asbestos (50 per cent silica, 40.5 per cent ferrous oxide and ferric oxide); kaolin, washed and ignited, technical (J. T. Baker Chemical Co., Phillipsburg, N.J.); talc: hydrated magnesium silicate.

Table 2. OXIDATIVE AND HYDROXYLATIVE CONVERSIONS PRODUCED BY QUARTZ AFTER VIGOROUS SHAKING WITH STARTING MATERIALS

Material	Product	Other oxidants used for confirmation
<i>D</i> -Proline	Hydroxyproline*†	H ₂ O ₂
β -Alanine	Glycine†	H ₂ O ₂ + Fe salts
Lysine	Hydroxylysine†	H ₂ O ₂ + Fe salts
Phenylalanine	Tyrosine*	H ₂ O ₂
Ascorbic acid	Dehydroascorbic acid*	Alumina
Thiamine	Thiochrome†	K ₂ Fe(CN) ₆
Adrenaline	Adrenochrome†	H ₂ O ₂ ; K ₂ Fe(CN) ₆
N-N dimethyl p-phenylenediamine	Wuister's red†	H ₂ O ₂
p-Phenylenediamine + α -naphthol	Indophenol purple†	H ₂ O ₂
Calcium gluconate	Arabinose*†	Fenton's reagent (H ₂ O ₂ + Fe salts)

* Dry shaking for 1 hr., then taken up in distilled water.

† Wet shaking throughout.

Hydrogen peroxide gave a greater yield of hydroxyproline compared with that given by quartz, and quartz added to a standard hydrogen peroxide-proline system gave the highest amount of hydroxyproline obtained. It is clear from Tables 1 and 2 that parallels exist between hydrogen peroxide and quartz-sponsored oxidations, and this suggests that quartz is functioning in a peroxidative capacity in most of the cases investigated. Kalyankar *et al.*³ obtained similar conversions with peroxide in the presence of iron salts.

In general, it seems evident that the conversions sponsored by quartz are catalytic ones in the presence of air, and possibly of the type mentioned by Johnson *et al.*⁴, where reactions involving free radicals *in vitro* were shown to simulate certain enzymatic processes.

It is not at the moment possible to relate these findings directly to the development of silicosis, and tentative suggestions only can be made. Quartz dust might give rise to peroxide in the tissues, or vitamin and hormonal activity might be interfered with at the site of deposition of dust. Furthermore, the possibility of the formation of toxic products from normal body constituents by the action of quartz should not be excluded: recent work (unpublished) in this laboratory by Marasas has shown that histamine and other imidazole derivatives are formed when histidine is allowed to react with quartz under simple laboratory conditions. In a different context, it has also been shown that measurable amounts of formaldehyde in some form or another can be readily detected in quartz and certain other dusts.

Finally, there is the possibility that quartz might in some way be involved in the direct synthesis of collagen from hydroxylated or oxidized precursor amino-acids or peptides, which might then be adsorbed on to the quartz surface in a manner similar to the template model proposed for such materials by Seifert⁵.

We wish to thank the director of this Unit, Dr. H. S. Gear, for facilities extended to us during this work, the sub-director, Dr. Ian Webster, for helpful discussions, and Miss M. J. Matthews for undertaking particle sizing and counting.

LETTERS TO THE EDITORS

ASTRONOMY

Bode's Law and the Solar System

IN a recent communication¹ a model was proposed for the formation of the solar system. It was suggested that tides produced on the Sun by a passing star caused portions of the solar material to break away at regular intervals of time, the intervals being governed by the natural frequency of oscillation of the disturbed Sun.

The most outstanding feature of the solar system is Bode's law, which relates mathematically the radii of the orbits of all the planets other than Neptune. In fact, the form of the law

$$r \propto 4 + 3 \times 2^n \quad (n = 0, 1 \dots 7)$$

does not really include Mercury as a natural member. However, it is clear that the correct explanation of the origin of the solar system must include Bode's law as one of its consequences. It will be shown that a model of the type already proposed, with some modifications suggested by computational experience, explains the radii of the planetary orbits with reasonable accuracy.

The details of the process will be best understood by reference to Fig. 1. The Sun is considered to have been at rest (for illustrative purposes only—any mathematical analysis must take account of its motion about the centre of gravity of the system) and the star to have approached on an orbit which took it to within a distance, D , of the Sun. The solar tide grew as the star approached and rotated to face the oncoming star. Eventually, a point of instability was reached², and the tip of the tide broke away and moved henceforth under the combined gravitational influence of the Sun and star. It has been confirmed by computation that the embryonic planet would be very little affected in its subsequent motion by the star, and its orbit around the Sun may be calculated from the height, R , and the angular velocity, ω , of the tide at the time of its inception. This orbit, assumed elliptical, will have a major axis of length:

$$a = \frac{GMR}{2GM - R^3\omega^2} \text{ and eccentricity } e = \left| 1 - \frac{R^3\omega^2}{GM} \right|$$

where M is the mass of the Sun and G the gravitational constant.

After an interval, t , another planet was formed. The value of R would have been the same as before, but ω would have been greater due to the angular acceleration of the star. The point of release of the planet may be defined by the angle θ shown in Fig. 1; it is assumed that ω was the angular velocity of the star at the appropriate value of θ . In fact, ω would be somewhat less than this value due to an inertial lag of the tide which would be expected to build up gradually as the star accelerated towards the perihelion of the orbit. Once this lag was sufficiently great, the process of detaching material from the Sun would have ceased.

The eccentricity of the original orbits will have been reduced by the passage of the planet through the

Fig. 1

material surrounding the Sun: tenuous though this may be, it has an appreciable effect over long periods of time. The planets for which $\omega < \sqrt{\frac{GM}{R^3}}$ have R

as aphelion distance; with $\omega > \sqrt{\frac{GM}{R^3}}$, then R is the perihelion distance. As a general rule, the eccentricity should be smallest for the innermost planets. Mercury is a notable exception to this rule; another exception is Neptune, the orbit of which is almost circular. This provides the clue to the value of R , because the orbit of Pluto, which is rather eccentric, actually intersects that of Neptune. This suggests that the orbit of Neptune was originally almost circular and that R was approximately equal to the radius of that orbit.

Since the retarding medium has a density which falls off fairly sharply with increasing distance from the Sun, the characteristic of the orbit which should remain approximately constant is the perihelion distance, $a(1 - e)$, which depends on the value of ω . For the two outermost planets, which have been under no appreciable restraint, the function $a(1 + e)$ is that which corresponds to ω .

The values which are being considered at present are:

Perihelion distance of Sun-star orbit	$D = 5.21 \times 10^{14}$ cm.
Tidal radius	$R = 4.30 \times 10^{14}$ cm.
Mass of Sun	$R = 2.20 \times 10^{33}$ gm. (about 10 per cent greater than at present)
Mass of star	$R = 3.39 \times 10^{33}$ gm.
Period between planetary formation	$t = 2.13 \times 10^4$ sec.

The star orbit is taken as parabolic.

The agreement between theory and observation is shown in Table 1.

Table 1

Planet	$t (\times 10^4 \text{ sec.})$	$\theta (^{\circ})$	$\alpha(1 \pm e)$	
			Theoretical ($\times 10^{13}$ cm.)	Observed ($\times 10^{13}$ cm.)
Mercury	?	?	?	0.46
Venus	0	96.4	1.09	1.08
Earth	2.13	92.3	1.53	1.48
Mars	4.26	87.5	2.12	2.05
X	6.39	81.8	3.17	—
Y	8.52	74.9	4.86	—
Jupiter	10.65	66.5	7.85	7.40
Saturn	12.78	56.1	13.42	13.43
Uranus	14.91	43.2	24.35	27.33
Neptune	17.04	27.5	45.00	45.30
Pluto	19.17	9.3	72.90	73.80

It will be seen that the agreement is generally good and that the following important features emerge: (i) Mercury does not fit into the system as, indeed, it does not fit properly into Bode's law. In view of the large eccentricity of its orbit, it is very unlikely to have started in its present course at the same time as the other planets. (ii) The model predicts two planets, X and Y in Table 1, between Mars and Jupiter. The asteroid belt may be explained as the debris of the collision of these planets. (iii) Neptune fits naturally into the planetary system and is not an odd member as Bode's law would suggest.

There have been substantial modifications of the model as originally put forward. In particular, the time-scale has been greatly increased (by a factor of about 10^5) and the origin of the asteroids is now explained as the results of a collision between two planets. However, the basic idea, that the planets were produced individually at regular intervals of time, has been preserved.

The full implications of the model are still being investigated, and, in particular, departures of the star-orbit from parabolic are being tried. Thus far, the model accounts satisfactorily for all those features of the solar system which have been examined.

The computations for this work were carried out on the University of Manchester Mercury computer, and I am indebted to the Electrical Engineering Department for the use of its facilities.

Spheroidal Oscillations of the Moon

PERIODS of natural vibration of three spherical gravitating models of the Moon have been calculated on an IBM 7090 electronic computer. The values provide basic information for lunar space-research concerned with the design of experiments to investigate the structure of the Moon.

Three completely solid models of the Moon have been treated, each with radius, $R = 1,738$ km., and mean density, $\sigma = 3.33$ gm./c.c. Model I is a homogeneous sphere having throughout velocities for P and S waves of $\alpha = 8.2$ km./sec., $\beta = 4.7$ km./sec., respectively. Since only the differences between the principal moments of inertia of the Moon are known¹, there is no direct evidence, at present, that it does not possess a core or have a concentration of mass towards the centre. Thus the following Roche laws of density distribution which fit the total mass were used to define the other models:

$$\begin{aligned} \text{Model II} & \quad \rho = 3.415 - 0.185x^2, \quad x = r/R \\ \text{Model III} & \quad \rho = 4.430 - 1.830x^2 \end{aligned}$$

The density distribution in Model II is close to that calculated by Jeffreys², for the self-compression of a Moon composed of ultrabasic rock with a surface density near 3.28 gm./c.c. Model III has a rather extreme density distribution having a surface value of 2.60 gm./c.c., near that of granite. This model was constructed to indicate the effect on the free periods of an internal lunar structure which has an increase of heavy material with depth (or a heavy core). Variations of P and S velocities with depth have been calculated in both Models II and III from the following velocity-density relationships which were based mainly on the P and S velocity distributions of Jeffreys² for the Earth and the density values of Earth Model A, constructed by Bullen³:

$$\begin{aligned} \alpha &= -2.40 + 3.12 \rho \\ \beta &= -0.00 + 1.52 \rho \end{aligned} \quad 2.5 < \rho < 4.5$$

(Linear velocity-density relations for longitudinal waves through considerable portions of the Earth's interior have been noticed by Francis Birch and J. E. Nafe (personal communication).)

The frequencies of the spheroidal oscillations were determined numerically from a sixth-order differential equation formulated by Hoskins⁴ and Alterman *et al.*⁵. For this type of vibration the displacement has, in general, both transverse and radial components which are affected by the gravitational attraction. Integration was by a fourth order Runge-Kutta method, through homogeneous shells of thickness 100 km., using floating-point arithmetic and about eight decimal digits. Some solutions were also computed using a shell thickness of 50 km. and the agreement between corresponding frequencies was between 1 and 5 per cent. (For the present purpose it did not appear worth while to use additional machine time in order to improve the fit between calculations for a layered sphere and for a sphere with continuous properties by increasing the number of layers.) As a programme test, the period of oscillation of order 2 for a homogeneous Earth (called by Alterman *et al.* (*loc. cit.*) Model β) was computed, using shells 100 km. thick. The present programme yielded a period of 44.37 min. compared with 44.3 min. given by Alterman *et al.* The calculated lunar periods are shown in Table 1.

The case of the purely radial vibration ($n = 0$) of Model I allows a check on numerical accuracy. Pekeris and Jarosch⁷ show that for a homogeneous sphere:

$$\alpha R / \tan \alpha R = (1 - \alpha^2 R^2 \alpha^2 / 4\beta^2)$$

and

$$\alpha^2 = (4\pi^2/T^2 + 4A)/\alpha^2$$

Table 1. PERIODS OF FREE VIBRATIONS (MIN.)

n		Models		
		I	II	III
0	Fundamental	8.73	8.7	7.5
	First higher mode	6.8	—	—
2	Fundamental	14.6	15.1	12.5
	First higher mode	8.0	8.4	8.1
4	Fundamental	4.9	—	—
	First higher mode	0.8	10.2	8.8
6	Fundamental	6.0	6.3	6.8
	First higher mode	7.7	8.0	7.2
8	Fundamental	4.8	5.1	5.6
	First higher mode	5.6	5.8	5.6
10	Fundamental	3.6	—	—
	First higher mode	—	—	—

where T is the vibration period, and surface gravity is AR . For Model I the highest solution of these equations is $T = 8.75$ min., in close agreement with the corresponding value in Table 1.

Concentration of mass towards the centre causes a relatively large reduction in the fundamental periods for $n < 6$. It is probable that for $n > 6$ the free periods of Models II and III again become markedly different (in the opposite sense) because motion would be largely confined to the surface region. The above results indicate that a measure of the deviation of the Moon from homogeneity is possible using observations of the long-period spectrum of free vibrations. An investigation of Press *et al.*⁹ has shown the capabilities of a single short-period seismometer in obtaining data on the deep interior of the Moon. This work suggests that, if the free vibrations are excited, an ultra-long period seismometer or tidal gravimeter designed to record periods up to 16 min. should provide more detailed information.

PHYSICS

Cesium-137 Fall-out over Norway since September 1956

In an earlier communication¹, we reported that concentrations of radioactivity in the lower stratosphere over south-east Norway had apparently increased for a month or two after high-yield test explosions, and then decreased with an effective half-life of about one month, corresponding to a residence half-life of about three months. Concentrations of radioactivity in the lower troposphere

Fig. 1. Fall-out over Norway since September 1956. Curve A, precipitation, mm./2 months; curve B, cesium-137/m.² 2 months; curve C, cesium-137/l. precipitation, averaged over periods of 2 months; curve D, gross $\beta/\text{l.}$ precipitation, averaged over periods of 2 months; curve E, effective age of fall-out materials, months. The points are plotted at the end of the 2-month periods. Each point represents an average value of measurements from ten stations

appeared to have increased for about six months, before decreasing at about the same rate as in the lower stratosphere. We suggested that deposition of fall-out materials from many explosions may have been fairly continuous, lasting months instead of years, and that during periods when explosions had

taken place rather frequently, there may have been considerable mixing of fall-out materials from different explosions.

These conclusions were based mainly upon measurements of gross β -activities. We have also investigated the problem by measuring concentrations of caesium-137 in the same precipitation samples, using a γ -spectrograph. The results are shown in Fig. 1 as mean values for each period of two months between September 1956 and June 1960. Curve *A* shows the mean values of precipitation; curve *B* the mean values of caesium-137 activity deposited per m.²; curve *C* the mean values of caesium-137 activity per litre of precipitation; curve *D* the mean values of gross β -activity per litre of precipitation.

Curves *C* and *D* are fairly alike with the main differences appearing shortly after large injections of fall-out materials.

Generally speaking, deposition of caesium-137 activity over Norway appears to have followed the same sort of pattern as the overall deposition of β -emitting isotopes. The rather rapid decrease of deposition during the last eight months or so of 1959, following a pattern visible on previous occasions for shorter periods, has not continued into 1960. However, it is questionable whether the change is of great significance in the fall-out of materials injected into the lower stratosphere during the latter part of 1958.

From information communicated by Dr. E. A. Martell, materials from high-yield, high-altitude injections during 1958 may not have reached the lower stratosphere in significant concentrations before about the beginning of 1960. Another factor which must be borne in mind in considering the 1960 values shown in curves *C* and *D* is that although the values are shown as activities per litre of precipitation, deposition without precipitation is also included. In relatively dry periods the activity of surface air tends to increase, with a resulting increase in the rate of dry deposition and in activity per litre of precipitation. Certain variations in activity per litre of precipitation (curve *C*) may therefore be partly due to the seasonal variations in the amount of precipitation (curve *A*).

By comparing caesium-137 activities with gross β -activities, it is possible to obtain some idea of the effective ages of deposited materials. The accuracy is limited because of the difficulties of calibrating β -counting equipment when measuring bomb debris of different ages and origins, and also because of uncertainties about the yields of caesium-137 relative to other radionuclides, and uncertainties about possible fractionation effects. Nevertheless, as shown in curve *E*, there is reasonably good evidence from caesium-137/gross β -activity ratios for the general conclusion that fall-out materials from many high-yield test series have reached the lower troposphere within a few months and been deposited rather rapidly.

The preponderance of materials from particular injections during different periods is well illustrated. From about the end of 1959, however, there appears to have been considerable mixing.

In conclusion we would like to suggest again that a large part of the fall-out from many test explosions has been rather continuous over months instead of years.

There has been no outstanding seasonal variation in the rate of fall-out which cannot be related to the

'seasonal variation' in test explosions and seasonal variation in the amount of precipitation.

New Delayed-Neutron Precursors

WITH the exception of a few cases (lithium-9, nitrogen-17 and thallium-210) all delayed neutron precursors so far identified¹ have been found among nuclides with two or more neutrons in excess of the major closed shells (50 and 82). The theory of delayed neutron emission probabilities given by Pappas² and the subsequent general systematics of delayed neutron precursors developed by Pappas and Rudstam³ predict, however, that delayed neutron emission should be much more common among neutron-rich nuclides than had been anticipated earlier. Delayed neutron precursors are now expected to appear from the lightest to the heaviest nuclides on the neutron-rich side of the β -stability line. The distance from it in *Z* should be from about 3 to about 7 charge units, depending on the neutron number³. A search was therefore made experimentally for some of these precursors.

Because of the complex mixture of delayed neutron activities already found in fission¹, an approach via fission would not be easy. Chemical separations should also be avoided because of the short half-lives expected. A feasible way of studying the prospective delayed neutron precursors would, however, be by the way of spallation reactions. These give products in highest yields near the target nuclide, whereas yields of distant products depend mainly on the irradiation energy. Therefore, by choosing suitable target elements and bombarding energies, it should be possible to detect and probably also to localize eventual delayed neutron precursors.

The short half-lives and the low neutron yield (the latter caused by the rather small branching ratio to the neutron-emitting state of the delayed neutron emitter) necessitate that the measurements start immediately after irradiation. This requirement was fulfilled by placing the neutron detector at a small radial distance from the irradiated target in the vacuum chamber of the synchro-cyclotron.

The neutrons emitted were thermalized by a layer of paraffin between the target and the neutron-sensitive scintillator properly shielded from stray radiation. The light pulses were fed through a light-guide to a photo-multiplier outside the fringing field of the magnet. The pulses were amplified and fed to a fast scaler provided with a printer. The counting started immediately after the end of irradiation.

A possible source of error in such measurements could be introduced by counting γ -rays from spallation products. The sensitivity of the detector for γ -rays is many orders of magnitude lower than for neutrons, but the intensity of the γ -rays involved is much larger than the intensity due to the neutrons.

Fig. 1. Influence of paraffin and cadmium shielding on the detecting efficiency of the neutron scintillator. Curves A and B were taken without, and with, cadmium, respectively. Curve C gives the difference between A and B

Therefore, to make certain that only neutrons were counted, experiments were carried out using various amounts of paraffin under otherwise identical irradiation conditions. A typical curve obtained for a copper target (15 mm. 'radial thickness') is shown in Fig. 1 (curve A). In this figure the corresponding curve obtained with 2 mm. of cadmium between the paraffin and the scintillator (curve B) is also shown.

Even if Fig. 1 shows that the majority of the counts obtained with cadmium shielding are due to neutrons (the detector is also sensitive to fast neutrons, although the sensitivity for thermal neutrons is about 20 times larger), it was found appropriate to take decay curves with and without cadmium under otherwise identical experimental conditions, and then analyse the difference curve. Thus any possible contribution from γ -rays is completely eliminated. The optimum condition regarding the amount of paraffin was found by taking differences between curves A and B in Fig. 1. These are given in curve C as a function of the thickness of paraffin.

In Fig. 2 analyses of decay curves obtained from irradiations of radially thick copper and neodymium targets are given. Apparently the copper difference curve 3 can be resolved into several components. A peeling-off analysis discloses two components with half-lives about 18 sec. and 8 sec., and in addition a third short-lived one.

The curve obtained by irradiation of uranium was too complex to be analysed, but the total neutron

activity was about five times larger than for copper under the conditions used.

Preliminary runs with neodymium (Fig. 2) disclosed activities with half-lives of about 20 sec. and 6 sec. These should presumably be due to the known¹ delayed-neutron precursors, 24.3-sec. iodine-137 and 6.3-sec. iodine-138.

It might be argued that the neutrons observed in these experiments are due to (γ, n) reactions induced in the targets or surrounding material by γ -rays from spallation products. The thresholds, however, for possible photo reactions are greater than 10 MeV.¹ Such energies are unlikely to be present in radioactive decay of spallation products, except for those having extremely low yield (far from stability). Moreover, the (γ, n) cross-sections involved are very small at these energies. Using very conservative estimates, about 1 of every 10^4 neutrons observed might be due to a photo neutron. Thus the activities found in copper are due to hitherto unknown delayed-neutron precursors.

Since the target itself moderates and to some extent absorbs the emitted neutrons, depending on its thickness in the radial direction toward the detector, it was found that the 18-sec. activity was suppressed, and only the 8-sec. activity appeared, when using a thin copper target. The opposite occurred when placing a cadmium sheet between a thick copper target and the paraffin. This filtering is caused by difference in kinetic energy of the delayed neutrons involved.

The new delayed-neutron precursors have not yet been identified by mass and charge, and the analysis of the decay curves might be more complex than assumed. Nevertheless, these findings give strong support to the validity of the delayed-neutron precursor systematics in the earlier papers^{2,3} and

Fig. 2. Delayed-neutron decay curves. Curves 1 and 2 were obtained without, and with, cadmium, respectively. Curve 3 is the difference curve. Curves are shown for a thick copper target + 3.9 cm. paraffin and for a thick neodymium target + 3.9 cm. paraffin. (The difference curves are lower by a factor of 10 on the scale of the graph)

to the hypothesis of the existence of many delayed-neutron precursors*. These experiments are therefore being extended to other elements of the Periodic System.

A detailed description of the apparatus used will be published elsewhere, as well as additional results, including attempts to identify the delayed-neutron precursors by different approaches.

Natural Occurrence of Samarium-146

Samarium-146 was discovered in 1953 by Seaborg and Dunlavey, who produced the nuclide by an intense bombardment of neodymium with α -particles¹. They reported that it emitted α -particles of 2.55-MeV. energy and decayed with an α -half-life of approximately 5×10^7 years.

Macfarlane and Kohman made a search for samarium-146 α -activity in natural samarium employing a large internal-sample cylindrical ionization chamber^{2,3}. They obtained a negative result and set an upper limit of 0.01 disintegration/gm./sec. for the specific activity in natural samarium.

A report has recently been made by Vorob'ev, Komar, Korolev and Solgakin of an indication for the existence of samarium-146 α -particles in the natural samarium α -spectrum although the level observed was not considered by them to be statistically significant⁴. They established an upper limit of 0.03 disintegration/gm./sec. for the specific activity.

The purpose of this work was to increase the sensitivity over previous measurements for the detection of a natural samarium-146 α -activity by counting a sample 'enriched in samarium-146'. This sample was obtained from the mass 146 position of a calutron collection plate which had been used in the separation of macro amounts of samarium isotopes from natural samarium.

The samarium oxide was deposited on a stainless-steel sheet and placed in an internal-sample cylindrical ionization chamber similar in design to that used previously by me⁵. It measured 50 cm. in length and 14 cm. in inside diameter, providing an active sample area of 2,000 cm.². The collecting electrode was a 0.13-mm. stainless steel wire strung axially along the full length of the counter and operated near ground potential. A negative potential of 1,400 V. was applied to the sample backing. The counter was operated as a flow-counter at 1 atm. pressure with a gas mixture of 93 per cent argon and 7 per cent methane.

Electronic amplification was provided by a 'ball and chain' preamplifier and a 'Miemar' main amplifier

Fig. 1. α -Particle spectrum of 'enriched samarium-146' sample

(designed and fabricated at the Lawrence Radiation Laboratory, Berkeley, California). The spectrum was recorded on a 100-channel pulse-height analyser (manufactured by Pacific Electro-Nuclear Corporation, Culver City, California).

An 89-mgm. sample (approximately 45 μ gm./cm.²) of the samarium oxide 'enriched in samarium-146' was counted for a period of 64 hr. The α -particle spectrum obtained is shown in Fig. 1. Only the samarium-147 peak was prominent; there was no significant indication of the presence of second peak in the vicinity of 2.5 MeV.

It was estimated that a peak in the region between 2.4 and 2.7 MeV. would have been recognized had one channel been 20 counts higher than the neighbouring channels for the 64-hr. period. From the spectra of natural samarium samples of similar thickness, it was found that the channel in which the main portion of the α -peak was contained accounted for 3 per cent of the total disintegration rate. From these data, a limit of 0.03 disintegration/gm./sec. was established for the specific activity of samarium-146 in this sample.

On comparison of the samarium-147 specific activity in the 'enriched samarium-146' sample with that for naturally occurring samarium, it appeared that an enrichment of 1.7 was realized for samarium-147. Based on the mass analyses of other samples which had been mass-separated under the same conditions, an enrichment of 1.7 in an adjacent mass (samarium-147) would correspond to at least a factor-of-10 enrichment in the isotope of interest (samarium-146), provided it had been present initially in low isotopic abundance.

In terms of the specific activity for an equivalent natural samarium sample, then, the limit would be smaller by a factor of 10 than for the 'enriched samarium-146' sample, or 0.003 disintegration/gm./sec.

Using the value of the half-life of 5×10^7 years obtained by Seaborg and Dunlavey¹, an upper limit

Table 1. SUMMARY OF RESULTS ON THE SPECIFIC ACTIVITY OF SAMARIUM-146 IN NATURE

Investigator	Specific activity (disintegration/gm./sec.)
Vorob'ev <i>et al.</i> (ref. 4)	≤ 0.08
Macfarlane and Kohman (refs. 2 and 3)	≤ 0.01
This work	≤ 0.003

for the isotopic abundance of samarium-146 can be calculated from the results obtained here. An upper limit of 2×10^{-7} per cent for the isotopic abundance of samarium-146 in natural samarium was calculated. The best mass spectrometric limit, obtained by Collins, Rourke and White; is 8×10^{-6} per cent (ref. 5).

Recently, the α -particle energy of samarium-146 (produced by bombardment of neodymium with α -particles) was rechecked and found to agree exactly with the value Seaborg and Dunlavey originally reported (2.55 MeV.) (M. C. Michel and R. D. Macfarlane, Lawrence Radiation Laboratory, unpublished results). From theoretical considerations based on this energy, an α -half-life in the neighbourhood of 6×10^7 years is favoured. If this is the correct half-life, all primordial samarium-146 should now be neodymium-142.

The co-operation of the Oak Ridge National Laboratory in specially preparing the samarium sample is gratefully acknowledged. This research was supported by the U.S. Atomic Energy Commission.

Radiation-induced Defects in Lead Silicate Glass

In attempts to explain the process of coloration of glass by γ -radiation, it was suggested in a previous communication¹ that electrons are trapped in defects to form colour centres. Not only do these defects already exist in glass but they can also be created by exposure to radiation. If defects could not be so created, it would be expected that the concentration of colour centres, as measured by the optical density, would increase exponentially to a saturation value at a certain dose. In practice, it is found that the optical density increases exponentially with dose up to about $10^{6.6}$ rads, but thereafter the increase is linear. This effect is shown in Fig. 1, which is divided into two sections having different scales for dose, the first section illustrating the exponential portion and the second the linear portion of the curve.

Fig. 1. Variation in optical density with dose (time after radiation, 1,000 min.).

Fig. 2. Increase in optical density on second irradiation. —, first irradiation; ---, second irradiation after bleaching.

The linear portion is attributed to the creation of defects by the radiation. Thus the extrapolation of the straight line to zero dose gives an indication of the defects already present in the glass. The difference between the extrapolated value at zero dose and the measured optical density is proportional to the concentration of defects produced by the radiation.

Exposure of irradiated glass to light at room temperature produces bleaching of the colour centres by excitation of the trapped electrons to such energy-levels as to enable them to escape from the defects and recombine with the positive holes. It might be expected that such treatment should release the trapped electrons but have little effect on the total number of defects. Hence such a bleached sample of glass should contain a greater concentration of defects or trapping centres than an unirradiated sample and, on further irradiation, should contain more colour centres than an originally unirradiated sample which is subjected to a first irradiation.

To test this theory a sample of the lead silicate glass used in the experiments described previously was given a dose of 10^6 rads of γ -radiation and its optical density was measured over the wave-length range 380–1,000 mμ at intervals of time during the week following the irradiation. The induced coloration was then bleached by exposure to light from a mercury lamp until the optical density of the glass was not significantly different from that measured before the irradiation. The sample was then given a further dose of 10^6 rads, and the optical absorption was again measured.

Fig. 2 shows the variation in optical density with time for four wave-lengths after the first and second irradiations. It can be seen that the optical density of the sample after bleaching and re-irradiation is at all times greater than that obtained after the first irradiation. This result is in accord with the proposed theory.

ENGINEERING

Beneficial Effects of Reagents in Solution on Wet Crushing of Rock

EARLIER workers in this Department^{1,2} have reported that substantial increases in the crushing efficiency of a drop-weight mill (stamp mill) may be achieved by pretreatment of the ore in aqueous solutions of certain reagents.

This work appears to have aroused interest, but, in the cases known to us, workers elsewhere have not been able to obtain significantly beneficial results^{3,4}. In these latter investigations a ball mill was used, and it is of interest that the first exploratory work at Leeds was carried out with a ball mill; the results were not encouraging³. Possible reasons for this, and for the final choice of a drop-weight mill, have been discussed by Frangiskos⁵; arguments are based on the work of Reh binder⁶.

In view of these later findings it has been considered necessary to repeat some of the experiments reported by Frangiskos and Smith¹ with the drop-weight mill. The results are given in Table 1. Except for the actual rock samples (limestone) used, the experimental conditions are the same as those employed by Frangiskos and Smith. The amount of crushing achieved is measured in terms of the surface area of the product, determined by a gas-permeability method. The percentage increase shown in Table 1 is the extra amount of crushing achieved when the ore is pretreated in a solution instead of in distilled water. The beneficial effect with the particular samples of limestone used is even more pronounced than that observed by Frangiskos and Smith; their best results represented approximately a 50 per cent increase.

Table 1. EFFECT OF REAGENTS IN SOLUTION ON THE SURFACE AREA OF CRUSHED ORE

Reagent (mgm./l.)	Sodium hydroxide		Sodium carbonate	
	Surface area of product (cm. ² /gm.)	Percentage increase (pure water basis)	Surface area of product (cm. ² /gm.)	Percentage increase (pure water basis)
0	247*	—	156	—
100	305	23.5	185	18.6
150	387	48.6	—	—
200	346	40.1	278	75.0
300	278	12.5	296	89.8
400	281	5.7	320	105.0
500	279	13.0	298	89.0
600	301	21.9	244	56.4
700	354	43.8	217	38.2
800	282	14.2	187	19.9

Charge to mill: 15 gm. limestone (−2.05 mm. + 1.40 mm.). Conditioning time in solution, 10 min. Weight of crushing head, 2,026 g. Height of fall, 13.6 mm. Blows per min., 120. Total number of blows, 600.

* Initial surface area approximately 1.5 cm.²/gm.

It is suggested that the reason for the success of the drop-weight method of crushing in contrast to the ball mill is basically as proposed by Frangiskos and Reh binder. The essential feature of the hypothesis is that embryo microcracks produced by stress on the solid are made permanent points of weakness by adsorption in them of ions or molecules from solution; it is assumed that the relative adsorption of water molecules is so small as to permit resealing of the microcracks. A drop-weight mill is likely to be more effective than a ball mill in producing microcracks.

Furthermore, the choice of method for assessing the amount of crushing (fineness of product) is important. Most of the new surface area produced is contained in the extremely fine sizes⁶, and the conventional sieve analysis gives no measure of this. Results which have been assessed in terms of a sieve analysis might therefore indicate no beneficial effect of reagents in solution. The work in this Department was terminated in 1956 after three years work due to lack of financial support. Finance has now been made available for the project for one more year, but it seems to us a pity that further development work on the process may have to be carried out elsewhere.

Hydrogen Diffusion in Water-accelerated Rolling Surface Fatigue

THE pitting failure of rolling bearings is now generally regarded as a surface fatigue phenomenon, and recent work¹ has shown that the presence of water in mineral oil lubricants can accelerate the failure of ball-bearings manufactured from conventional E.N.31 steel. A possible mechanism for this phenomenon has been suggested by Grunberg and Scott². The hypothesis is that vacancy-induced diffusion of hydrogen into the highly stressed surface material produces 'hydrogen embrittlement'. To test this theory, four-ball rolling tests^{1,2} were carried out with a lubricating oil containing 6 per cent tritiated water of high activity (5 c./ml.). The rolling four-ball test produces a track on the driving ball in which pits are normally formed. The three driven balls are stressed to a lesser extent and usually do not show evidence of surface fatigue. Balls from tests using tritiated water were washed with acetone and partially immersed in a liquid scintillator (0.3 per cent 2,5-diphenyloxazole + 0.01 per cent 1,4[2-(5-phenyloxazolyl)]-benzene in toluene) and the activity counted using a (refrigerated) ECKO N612 unit. When the part of driving balls carrying the fatigued track was immersed in the liquid scintillator, counting-rates of between 1,000 and 2,000 counts/sec. were recorded. The unfatigued part of driving balls gave only counts of about 40 counts/sec. against the background count of 30 counts/sec. The activity in the fatigued tracks decreased with time and tended towards the background-level after about five days.

The preliminary experiments described provide support for the hypothesis that, in the presence of water, hydrogen penetrates into the material subject to surface fatigue. The decrease in activity with time can be ascribed to escape of tritium from the material.

The phenomenon is now being investigated in greater detail.

METALLURGY

Fatty Acids and Adhesion of Electrodeposited Metals

THE deleterious effect of grease on the substrate on the adhesion of electrodeposited metals is well known, but quantitative data are sparse. A systematic study of the influence of monolayers of adsorbed surface-active agents on the adhesion of electrodeposits is in progress in this laboratory, and this communication reports the initial results obtained from the fatty acid series.

The adhesion was measured in the manner described by Williams and Hammond¹, with the test-pieces made of copper. The ends of the specimens to be plated were polished to 1 μ diamond powder, electropolished in 50 per cent phosphoric acid and treated to have a monolayer of the fatty acid under test². The acids used were the even-numbered acids of the series $\text{CH}_3(\text{CH}_2)_n\text{COOH}$, where $n = 4-16$. The specimens with the monolayer were plated with nickel from a conventional Watts type solution at a pH of 4, temperature of 40°C., and a current density of 20 amp./sq. ft. until a deposit of at least 0.1 in. had been produced. After plating, the specimens were tested in a Denison tensile testing machine. To provide a reference point, a series of specimens was tested using the exact procedure outlined except that no fatty acid was used.

Fig. 1. Adhesion of electrodeposited nickel as a function of fatty acid chain-length

The results are shown in Fig. 1. They were reproducible for each acid, and when the experiment was repeated with caprylic acid ($n = 6$) the adhesion values were within a few hundred pounds per sq. in. of each other. The adhesion appears to be independent of the chain-length of the fatty acid when n is greater than 8 or 10; as n decreases below this value the adhesion progressively increases. This increase can be explained either by the increased desorption of the shorter-chain acids resulting in the nickel being discharged directly on the copper lattice, or by a decrease in the long-range forces between copper and nickel as the distance increases. It is impossible to distinguish between these alternatives at this stage, but it may be pertinent that there is no evidence of epitaxis.

Fatigue Straining of Copper Whisker

BRENNER¹ has shown that copper whiskers can be strained elastically to as much as 2.8 per cent in tension. I have found that similar whiskers remain elastic in cantilever bending at static strains up to 4 per cent corresponding to a stress of 470 kgm./mm.² in a whisker of <110> orientation.

When plastic deformation occurs it is by 'kinking', as has been described by previous workers² with other materials. The 'kink' formed is a bend of radius of curvature of the order of the thickness of the whisker; it is produced suddenly, with release of the elastic strain in the rest of the whisker. It can be shown that this behaviour is to be expected from a cantilever bent by a 'hard' device, if it is of a material that has clearly defined upper and lower yield points and yield extension. These phenomena are very pronounced in copper whiskers³.

I have performed experiments to see whether the behaviour of copper whiskers under repeated straining differs from that under static conditions. The experiments were performed in cantilever bending with the whisker encased in diphenyl carbazide glass⁴ and deflected by a 'hard' probe. The whiskers were grown by hydrogen reduction of cuprous iodide⁵.

Since the static strain at which kinking occurs varies very much from one whisker to the next, it was not possible to test whiskers in cyclic loading at a known fraction of the static kinking strain. Instead, whiskers that were less than about 3 μ thick, straight and optically smooth, were selected and were then tested as follows.

A whisker was bent to a strain, S (≈ 1 per cent), which it was thought very likely to be able to sustain elastically. The bending-probe was then removed, and the whisker examined for permanent bending. If there were none, the probe was then made to vibrate so that the maximum strain in the whisker fluctuated between 0 and S at 900 c./s., the test being observed stroboscopically. After 10⁶ cycles of vibration the probe was stopped and removed. If no permanent deformation had taken place, a static strain of $(S + \Delta S)$ ($\Delta S \approx 0.3$ per cent) was applied, and the whole procedure repeated, the vibrations being this

time with maximum strain fluctuating between 0 and $(S + \Delta S)$. This procedure was repeated with successive increments of strain. Thus the whisker was subjected, at each value of strain amplitude, to one slow (quasistatic) cycle of strain, followed, if nothing had happened, by 10^6 fast cycles.

I found that whiskers were generally capable of surviving such tests apparently unaffected to strains of the order of 3 per cent, with 10^6 strain cycles at each value of strain amplitude. Then, during the next period of oscillatory straining, at a slightly higher strain, the whisker would suddenly kink, after it had already been subjected to a large number of cycles at this high strain. The kinking would be instantaneous, so far as could be judged by eye; that is, it must have happened in less than 100 cycles. The vibrator would reach maximum amplitude in at most a few hundred cycles, and kinking was observed less than a few thousand cycles after the increment of strain was made. Several times the kinking occurred after more than 10^6 cycles.

The strains at which whiskers kinked dynamically were not very reproducible, just as the static kinking strains show a large scatter¹. It sometimes proved possible to re-embed a whisker that had kinked dynamically in such a way that the undeformed part of the whisker could be re-tested. The strain at which dynamic kinking occurred was then of the same order as in the first experiment. For example, a whisker that had kinked after being strained from 0 to 1.9 per cent for 10^6 cycles was re-embedded; it afterwards withstood 10^6 cycles at 0.1-1.1 per cent and 10^6 cycles at 0.1-7 per cent strain and it kinked after 10^6 cycles at 0.2-3 per cent strain.

If the vibrator was stopped immediately after the whisker kinked, then the whisker looked just as if it had kinked statically. The kink was a plastic hinge, but its appreciable strength often made it possible to continue elastic vibrations with much-reduced amplitude (perhaps 0.3 per cent elastic strain). When this was done, the whisker usually fractured in the kink after a few thousand cycles. As a corollary, if the vibrator were not stopped when the whisker kinked, fracture occurred a few thousand cycles after kinking. Fracture was never observed in oscillatory loading of this type unless kinking had occurred first.

If the whisker was fixed both at the root and to the vibrator (instead of merely being pushed by the latter) and vibrated so that the strain oscillated symmetrically about zero, then fracture did occur. But in this case kinking was not easily detectable, and, if it had taken place, the plastic kink would have been subjected to large cyclic strains, so that it would have failed very quickly, perhaps too quickly to see the kinking. Therefore this test does not provide adequate evidence of the existence of fatigue fracture in elastic whiskers.

Whiskers were also statically strained for periods long compared with the times of the oscillatory experiments. Kinking was never observed unless it happened immediately the strain was applied. This shows that the delayed kinking is due to the oscillatory loading and not to the passage of time.

Both statically and dynamically kinking occurs near the root of the whisker, where it is embedded in diphenyl carbazide glass and where the bending moment, and hence the elastic strain before kinking, are greatest. But the kink very often starts, not at the point of entry of the whisker into the glass, but at

distances up to ten times the thickness of the whisker away from that point, towards the free end. Therefore, the failure of the whisker is not determined by stress concentration or corrosion at the point of entry into the glass: the concentration is probably small, owing to the low elastic modulus of the glass compared with that of the copper, and to the wetting-fillet, the radius of which is of order $\frac{1}{2}$ the whisker thickness. The failure is more probably precipitated by stress concentration at defects in the whisker⁴.

There is much evidence⁶ that in copper whiskers subject to large, static, elastic strain, no slip occurs below the yield point. We have shown that if they are subjected to large, repeated, elastic strain, fatigue fracture is not observed, even at strains of the order of 3 per cent. The sudden onset of plastic flow does occur; the reason for this is not understood, and is being investigated. As soon as the whisker has flowed plastically, it can fracture in fatigue, in the yielded region, at quite small, mainly elastic strains. This serves to confirm the belief, hitherto assumed without direct evidence, that slip is an essential process in fatigue failure.

I wish to thank Mr. H. B. Holland, who has carried out these very delicate experiments. This communication is published by permission of the Ministry of Power.

RADIOCHEMISTRY

Effect of γ -Radiation on Nisin

THE antibiotic nisin is known to reduce the heat-resistance of spore-forming organisms, and consideration has been given to its use as an additive to lower the heat-process requirements of canned foods¹. The radiation resistance of spore-formers might also be influenced by nisin, and the dose required for the sterilization of food lowered to a level where radiation-induced flavour and odour changes are not detectable.

Experiments were first conducted to determine the effect of radiation on the antibiotic activity of nisin when it was suspended in a variety of media and at different pH values. Samples were made up in McCartney bottles in triplicate and irradiated with γ -rays at a dose-rate of 1×10^6 rads/hr. using a 10,000 c. cobalt-60 source. The temperature of the samples was maintained at 4° C. during irradiation and until assay, 30 hr. after their preparation. Nisin was assayed using both the resazurin² and plate methods³, the latter being modified to handle liquid samples.

The result of irradiation with a dose of 2.7 megarads is shown in Table 1. At this dose-level nisin activity is completely destroyed irrespective of the nature of the suspending medium or of the pH in the short

Table 1

Media	Nisin concentration (U./ml.) mean of triplicates			
	Theoretical	Before irradiation	After 30 hr. storage (controls)	Irradiated 2.7 megarads
Sterile skim milk	200	220	190	< 4
Sterile skim milk	2,000	1,900	1,750	< 4
Unprocessed soup				
pH 6.08	200	—	238	< 4
Processed soup				
pH 5.85	200	—	180	< 4
pH 3.5 phthalate buffer	200	175	170	< 4
pH 5.0 phthalate buffer	200	235	200	< 4
pH 6.0 phthalate buffer	200	200	205	< 4
Pure nisin in sterile distilled water	2,000	2,250	2,250	< 4

range studied. No activity could be detected even when the initial concentration of nisin was increased from 200 to 2,000 U./ml. as shown in skim milk and distilled water. No significant loss of unirradiated nisin occurred during the 30-hr. period of the experiments. The soup medium used was a meat and vegetable broth chosen to demonstrate any possible protective effect which might be exerted by food constituents.

Sterile skim milk with an initial concentration of 200 U./ml. of nisin was chosen as suspending medium to study a range of radiation dose-levels. The experiment was run in triplicate and results are shown in Table 2. At the lower levels about 17 per cent of activity is lost, there is a marked drop at 0.5 megarad when 80 per cent is lost and a complete loss occurs at 1.5 megarads and above.

Table 2

Dose (megarad)	Nisin concentration (U./ml.) mean of triplicates	
	Rosazurin method	Plate method
Nil (control)	183	182
0.13	153	152
0.25	150	153
0.5	37	24
0.75	< 20	22
1.0	< 20	14
1.5	< 20	< 5
2.0	< 20	< 5
2.5	< 20	< 5

The evidence presented indicates that nisin added to foodstuffs prior to radiation processing will be rendered ineffective against bacterial spores which survive the radiation treatment, especially in the sterilization dose-range of 1–3 megarads. There is a possibility, however, that nisin might be protected from radiation damage to some extent in the presence of spores, particularly if it acts by absorption on the spore coat.

CHEMISTRY

Electron Paramagnetic Resonance Studies of Stable Free Radicals in Lignins and Humic Acids

ELECTRON paramagnetic resonance studies¹ of wood; lignins; tannins, and humic acids, such as are found in soils and coals, show an electron paramagnetic resonance line of 6 ± 2 gauss width at $g = 2.003 \pm 0.002$, indicating the presence of a free radical. I find that this free radical is stable over a period of years in air and is not present in protolignin in plant materials nor is it necessarily the result of simple ageing or rotting of wood. However, it is formed when protolignin in plants is polymerized into lignin by either acid or fungal attack. I also find that the 6 ± 2 gauss electron paramagnetic resonance line is restricted to the fraction of humic material which is extractable with aqueous bases.

Freudenberg² indicates that lignin polymerization results from dehydrogenation or oxidative removal of a phenolic hydrogen on coniferyl or sinapinic alcohol or by hydrolysis of a phenolic glycoside linkage. According to Freudenberg the polymerization is a free-radical process involving a semi-quinone radical intermediate. My electron paramagnetic resonance results indicate that free radicals are indeed present and that some free radicals persist in the lignin polymer where they are protected from their macro-environment. They survive within the lignin micelles through the process of coal formation and persist apparently for geological time ($\sim 10^6$ years).

Air-dried fresh wood samples (fine shavings) of oak, pine, eucalyptus, redwood, and spruce showed a very low free radical concentration of $< 10^{14}$ spins per gram (s./gm.). The carbon disulphide-soluble, absolute ethanol-soluble, and dioxane-soluble Soxhlet fractions (extracted in this order) and the corresponding residual wood fractions showed no electron paramagnetic resonance ($< 10^{14}$ s./gm.). Dioxane (catalysed by hydrochloric acid) lignin extracts showed strong electron paramagnetic resonance $\sim 10^{18}$ s./gm. at $g = 2.00$ even though the lignin precursors in the wood did not. A similar high free-radical content was observed with a 'Soxhlet' water extraction that turned acid by formation of organic acids from the wood. Electron paramagnetic resonance was not evident in the unfractionated cellulose and pentosan fractions of wood. Freshly cut redwood ranging from sapwood to rotted heartwood (40 years old) showed no difference in a very weak electron paramagnetic resonance signal. Scots pine buried for 600 years in damp soil, and spruce buried for more than 450 years³ likewise showed no, or barely detectable, electron paramagnetic resonance. These same woods showed depletion of cellulose and pentosans, but no change of lignin concentration. On the other hand, fresh pine needles about to drop from a tree but already attacked by fungi, and plant debris which had collected in soil as peat showed strong electron paramagnetic resonance with both a line of 8 gauss and a broad line of 1,000–1,200 gauss both centred on $g = 2.00$ (Fig. 1a). The material showing the sharper electron paramagnetic resonance line is extractable with an aqueous base (Fig. 1b) and behaves as the polyelectrolyte humic acid while the broad line (Fig. 1c) characterizes the non-extractable residue. Tannin extract (quebracho) showed the same 6-gauss

electron paramagnetic resonance line shown by humic acids.

These results suggest that lignin does not normally occur in living plants. Rather it is the polymerization product of those compounds capable of forming or reacting with semiquinone free-radicals formed during dehydrogenative or hydrolytic degradation of plant tissue. These polymers with their trapped free radicals in turn survive the geochemical processes of humification and coalification without loss of their free radicals. This suggests that post-depositional chemical modifications do not destroy the aromatic semiquinoid properties of these compounds.

It should be remembered that not only aromatic —OH groups but also aromatic —NH₂⁴ and aromatic —SH⁵ groups can be dehydrogenated to yield semiquinone-type radicals. For this reason a wide range of compounds can be expected to contribute to the formation of natural semiquinone polymers such as lignins, humic acids and tannins.

The comments and assistance of my colleagues and the research assistants at this Laboratory have been both helpful and stimulating. Especial appreciation is due to Dr. R. R. Unterberger for providing the facilities of his electron paramagnetic resonance spectrometer.

Surface Renewal and Molecular Diffusion in Interphase Mass Transfer

IN 1953 Lewis and Pratt¹ described violent spontaneous movements of the liquid-liquid interface which they observed during measurements of interfacial tension in the presence of mass transfer by the drop-weight method. These phenomena have since been investigated more fully²⁻⁵. It is now generally accepted that they are due to the formation of local gradients of interfacial tension caused by local variations of solute concentration at the interface as the result of mass transfer.

It can be argued that such spontaneous 'interfacial eruptions' would cause considerable portions of the interface to be replaced by fresh liquid from the interior and thus result in an increase of the rate of surface renewal. This could mean that for solutes of different interfacial properties the rates of mass transfer may be different even under conditions of equal flow parameters of the bulk phases and equal molecular diffusivities. No conclusions can thus be drawn from such experiments about the effects of molecular diffusivity on the transfer process. If, however, the transfer of two solutes takes place simultaneously, that is, under identical interfacial as well as hydrodynamic conditions, some conclusions could be arrived at. In order to test this possibility, experiments were conducted on the separate and simultaneous transfer of propionic acid and phenol between carbon tetrachloride and water, using vertical and horizontal laminar co-current liquid-liquid contactors with moving interface.

From the theory of mass transfer with surface renewal⁶ it can be shown that for the transfer of a solute *A* between two immiscible solvents 1 and 2 the overall resistance to mass transfer, *R_A*, can be expressed as:

$$R_A = (1/\sqrt{D_1} + m/\sqrt{D_2})/s_A = 1/\sqrt{(d_A s_A)} \quad (1)$$

where *s* is the fractional rate of surface renewal; *D*₁, *D*₂ the solute diffusivities in the two phases; *m* the distribution coefficient; and *d* an effective overall diffusivity. Thus, for the separate transfer of the two solutes *A* and *B*:

$$R_A/R_B = \left(\frac{d_B s_B}{d_A s_A} \right)^{1/2} \quad (2)$$

and for simultaneous transfer, since *s_A* = *s_B*:

$$R_A/R_B = (d_B/d_A)^{1/2} \quad (3)$$

The results obtained for separate transfer of phenol and propionic acid at equal Reynolds numbers could not be correlated by equation (3), thus indicating that for the two cases the rates of surface renewal were different. Observations on simultaneous transfer, involving transfer of phenol in either direction but of propionic acid from carbon tetrachloride to water only, covering a thirty-fold range of *R* and a four-fold range of *m_A/m_B*, confirm that equation (3) holds within 95 per cent confidence limits of ±5 per cent. In all the runs the existence of interfacial turbulence was confirmed by visual or schlieren observation. Thus it is highly probable that, under conditions of spontaneous interfacial turbulence, the rate of mass transfer depends to a large extent on the induced rate of interface renewal and is directly proportional to the square root of molecular diffusivity. Values

of fractional surface renewal up to 100 per sec. were found.

Growth and Adhesion of Oxide in Furnace Deposits

DURING the oxidation of steel there are formed on the surface a variety of needle or plate-like growths of oxide which, for convenience, have been called 'oxicles'. The present investigation, supported by and in collaboration with the Thornton Research Centre of Shell Research, Ltd., began with the idea that these oxicles might entrap particles in burnt gases and thus act as the nucleation for the build-up of ash deposits. Accordingly a series of experiments have been undertaken in which specimens of 5 per cent chromium, 0.5 per cent molybdenum steel sheet have been oxidized in an oil-burning rig and examined by reflexion electron microscopy.

The results show, first, that whether or not oxicles are formed by pre-oxidation in air before the specimens are put into the oil-burning rig, the subsequent growth is similar. Secondly, there is a very large difference between the oxicle growth which occurs when the specimen is exposed to clean oil products and that obtained with oil containing a soluble metallic salt expected to give greater build-up of deposits. In the first case the growths are small, as

shown in Fig. 1, whereas in the second case when oil containing a soluble metallic salt is used, large spiky oxicles occur of composition as yet unknown and these in turn do seem to collect very small particles of ash among their branches in accord with the original hypothesis (Fig. 2). Thus, although the oxicles trap some fine ash particles, this mechanism is not necessarily the dominant factor in the build-up of deposits.

The mode of attachment of the fluffy material at the tops of some of the oxicles suggested an electrical effect. The oil-burning apparatus was therefore modified so that the specimen holder was insulated from the rest of the rig and could be raised to $\pm 3,000$ V. with respect to it. Depending on the sign of the applied voltage, there was a marked difference in oxidation behaviour. In the tests with positive or zero potential, the scale was adherent, and the specimen developed a dull surface finish; but in the tests where the charge was negative, the scale was non-adherent and the metal surface retained a bright appearance. The pick-up of fine ash material did not seem to be appreciably affected. Fig. 3 shows the flaking away of the oxicle growth after oxidation with $-3,000$ V. applied to the specimen.

Work is proceeding to investigate these effects more fully.

New Data for the Calcium Silicate, 'Phase 2'

THIS compound was first described by Roy^{1,2}, who considered it to be $9\text{CaO} \cdot 6\text{SiO}_2 \cdot \text{H}_2\text{O}$. Further work now shows that, while specimens prepared at relatively low temperatures and pressures may be hydrated, those prepared at sufficiently high temperatures and pressures are anhydrous, with the composition $\text{Ca}_3\text{Si}_2\text{O}_7$. They also establish the approximate unit cell parameters.

Fig. 1. Oxicle growth on 5 per cent chromium, 0.5 per cent molybdenum steel sheet after 15 min. at 600°C . in air plus 6 hr. at 600°C . in an oil-rig burning pure kerosene. ($\times 2,960$)

Fig. 2. Oxicle growth on 5 per cent chromium, 0.5 per cent molybdenum steel sheet after 15 min. at 600°C . in air plus 6 hr. at 600°C . in an oil-rig burning kerosene containing 1 per cent of a soluble metallic salt. ($\times 1,480$)

Fig. 3. Oxicle growth on 5 per cent chromium, 0.5 per cent molybdenum steel sheet after 30 min. at 600°C . in air followed by 6 hr. at 600°C . in an oil-rig burning kerosene containing 1 per cent of a soluble metallic salt. A potential of $-3,000$ V. was applied to the specimen. ($\times 960$)

A specimen prepared hydrothermally at 715° C. and 1,100 bars showed negligible loss of weight over the range 100–1,400° C. There was no change in X-ray powder pattern up to 954° C., but by 1,090° C. transformation to rankinite had occurred. Specimens prepared under these or similar conditions are therefore anhydrous. 'Phase Z' can, however, also be obtained at temperatures at least as low as 200° C., and it seems unlikely that a product so obtained would be anhydrous. Preliminary results suggest that, as the temperature of preparation decreases, the phase becomes hydrated and that its calcium:silicon ratio rises. This can possibly be attributed to a hydrogarnet-like replacement of Si by 4H, which would cause the composition to trend towards $6\text{CaO} \cdot 3\text{SiO}_2 \cdot 2\text{H}_2\text{O}$. So-called 'dicalcium silicate hydrate (C)'², and similar preparations, appear to be mixtures consisting principally of lime-rich 'phase Z' with smaller amounts of calcio-chondrodite ($\text{Ca}_2(\text{SiO}_4)_2(\text{OH})_2$).

The equilibrium P – T curve for the transformation of 'phase Z' into rankinite has been reported previously². Further work suggests that this curve represents a metastable equilibrium, as sufficiently long runs under conditions lying in the 'phase Z' field yield 'phase Y' ($6\text{CaO} \cdot 3\text{SiO}_2 \cdot \text{H}_2\text{O}$) and wollastonite or foshagite, with or without 'phase Z'. The latter is therefore probably always metastable, at least at the higher temperatures at which it is formed. This, together with the supposedly variable composition, may explain the difficulty of preparing large crystals: the compound disproportionates before these are able to grow. From a combination of selected area electron diffraction and X-ray powder photographs for several specimens, the unit cell was found to be orthorhombic or pseudo-orthorhombic, body-centred, with a 5.07, b 11.3, c 23 Å, approx.; the crystals are flaky with (001) cleavage. These parameters were confirmed by X-ray study of single crystals of afwillite ($3\text{CaO} \cdot 2\text{SiO}_2 \cdot 3\text{H}_2\text{O}$) which had been first heated in air at 500° C. and afterwards treated hydrothermally at 200° C. under saturated steam pressure; these crystals contained both 'phase Z' and tobermorite, both in strongly preferred orientation. The calculated density, assuming cell contents $8(\text{Ca}_2\text{Si}_2\text{O}_7)$, is about 2.9 gm./c.c. This agrees with the value of 2.99 gm./c.c. calculated from the mean refractive index of 1.652² by the method of Howison and Taylor¹.

The unit cell of 'phase Z' is closely related to those of $\gamma\text{-Ca}_2\text{SiO}_4$ and calcio-chondrodite, the face with approximate parameters a 5.07, b 11.3 Å., γ 90° being common to all three compounds. We have found that 'phase Z' forms particularly readily on hydrothermal treatment of $\gamma\text{-Ca}_2\text{SiO}_4$; this can perhaps be attributed to a structural resemblance. It is often difficult to distinguish 'phase Z' from calcio-chondrodite by selected area electron diffraction, as in both cases the crystals normally lie on the face mentioned above. Distinction can be made by the fact that the lattice of 'phase Z' is body-centred, while that of calcio-chondrodite is primitive, and also by the differing values of c . These differences are only detectable, however, if the Laue zones corresponding to different l -indices are well resolved; for this purpose a tilting stage technique can be used³. If they are not well resolved, c cannot be determined, and 'phase Z' shows an apparently primitive lattice indistinguishable from that of calcio-chondrodite.

Further work is in progress, and a fuller account will be published later.

BIOCHEMISTRY

Different Action of 2:4-Dinitrophenol on the Oxidation of Exogenous and Endogenous Substrates by Baker's Yeast

It is recognized¹ that 2:4-dinitrophenol (DNP) stimulates the total oxidation of glucose by baker's yeast, which takes place mostly through the combined action of the Embden–Meyerhof and the citric acid cycles². Nevertheless, the oxidation of pyruvate, a compulsory intermediate of glucose degradation in yeast, is strongly inhibited by DNP in the same experimental conditions that stimulate glucose oxidation³. In order to elucidate this apparent contradiction our previous experiments have been extended using substrates labelled with carbon-14.

Table 1 shows that with $[3\text{-}^{14}\text{C}]$ pyruvate, DNP prevents incorporation of carbon-14 into the cells, the evolution of radioactive carbon dioxide and the oxygen uptake. On the other hand, with $[6\text{-}^{14}\text{C}]$ glucose (or $[1\text{-}^{14}\text{C}]$ glucose), which yields $[3\text{-}^{14}\text{C}]$ pyruvate inside the cell, DNP stimulates the oxygen consumption and evolution of labelled carbon dioxide, and, accordingly, diminishes incorporation of carbon-14 into the cell constituents. It is noteworthy that in the presence of DNP, the total carbon-14 counted in carbon dioxide from $[6\text{-}^{14}\text{C}]$ glucose is about that obtained from exogenous $[3\text{-}^{14}\text{C}]$ pyruvate (without DNP).

Enhancement by DNP of glucose oxidation through the pentose pathway², which does not involve pyruvate as an intermediate, can be ruled out because in experiments carried out separately the ratio of the specific activities of carbon dioxide formed after simultaneous oxidation of glucoses marked in the C-1 and C-6 respectively is not increased by DNP. Furthermore, paper chromatograms and radioautograms of the methanol–water extracts from the yeast cells after oxidation of $[3\text{-}^{14}\text{C}]$ pyruvate or $[6\text{-}^{14}\text{C}]$ glucose show, qualitatively, the same distribution of carbon-14 in the citric acid-cycle and related substances. From this evidence, it may be concluded that the action of DNP on exogenous pyruvate consumption is not due to inhibition of the mechanism of pyruvate oxidation (the citric acid-cycle) but rather to diminished accessibility of pyruvate to the cell compartment where the oxidation takes place. Similar results are found with $[1,4\text{-}^{14}\text{C}]$ succinate and $[^{14}\text{C}]$ glutamate (Table 1) and also with $[1,4\text{-}^{14}\text{C}]$ fumarate.

Starved baker's yeast (8.1 mgm., exp. A and 23 mgm., exp. B) suspended in 2.0 ml. 25 mM phthalate buffer with additions as shown. 5 μ C. [3-¹⁴C]pyruvate and [6-¹⁴C]glucose: 2.5 μ C. [1,4-¹⁴C]succinate and 2 μ C. [¹⁴C]glutamate (1 μ C. = 1.19 10⁴ counts/min.); final pH, 4.5; 0.15 ml. 5 N sodium hydroxide (carbonate free) in the central well of the Warburg flask; air in the gas space; temperature, 30°. After incubation (2 hr. exp. A and 3 hr., exp. B) the carbon dioxide absorbed in the alkali was precipitated as barium carbonate, washed, filtered, weighed and the radioactivity counted. The yeast suspension was diluted with 5 ml. cold phthalate buffer and centrifuged at 1°. The dilution and centrifugation were repeated and the yeast cells finally suspended in 5–10 ml. methanol for carbon-14 counting. Experimental details as before (ref. 8).

If non-radioactive glucose is added to the yeast cells in the presence of the substrates referred to and DNP, the later inhibitory action diminishes as shown by the comparatively higher incorporation of carbon-14 into the yeast cells and the total amount of carbon-14 in the carbon dioxide evolved (Table 1). Glucose effect is particularly noteworthy if it is taken into account that the carbon-14 from pyruvate becomes diluted with glucose carbon, which dilution is reflected by the relative diminution of specific activity of carbon-14 in the respiratory carbon dioxide. With the dicarboxylic acids and glutamate, the action of glucose is more striking because glucose increases absolute incorporation of carbon-14 into the yeast cells or in carbon dioxide, irrespective of the presence of DNP.

Yeast cells are divided by membrane barriers into an outer region identical with the cell wall, and a central region where organic acids like pyruvic, succinic, fumaric, glutamic, glycine, etc., do not enter or enter at a slow rate⁴. The central region includes the cytoplasm and mitochondria⁵ that catalyse the citric acid cycle oxidations⁶. On these grounds, the results quoted support the hypothesis that, as in other instances⁷, the transfer of substrates across the yeast membranes is an active, metabolically controlled process.

With ¹⁴C-acetate as substrate, which oxidation is also inhibited by DNP⁸, similar results can be observed, namely, inhibition of the oxygen uptake, the incorporation of carbon-14 into the cell constituents and the evolution of labelled carbon dioxide; the addition of glucose strongly decreases the effect of DNP. At variance with the other substrates studied, acetate diffuses freely into the yeast cell inner compartment⁴, and its oxidation through the citric acid cycle in yeast requires as initial step activation with adenosine triphosphate¹⁰, or in other words, is dependent on energy. The already established uncoupling action⁹ of DNP on oxidative phosphorylation in yeast seems to be, therefore, the ultimate mechanism of the inhibition of substrate oxidation at the citric acid cycle-level. The effect of glucose can be easily understood because DNP

does not inhibit phosphate esterification during glycolysis¹¹.

Mechanism of Activation and Reduction of α -Aminoadipic Acid by Yeast Enzyme

PREVIOUSLY¹ we reported the reduction reaction of α -aminoadipic acid by a yeast enzyme(s) which will now be referred to tentatively as α -aminoadipic acid reductase. The reaction by which α -aminoadipic acid is converted to the corresponding δ -semi-aldehyde requires the participation of adenosine triphosphate, reduced triphosphopyridine nucleotide and Mg⁺⁺, and the enzyme is activated by glutathione. The present communication reports the formation of δ -adenyl- α -aminoadipic acid by the α -aminoadipic

Table 1. REQUIREMENTS FOR THE PYROPHOSPHATE (PP)-ADENOSINE TRIPHOSPHATE (ATP) EXCHANGE REACTION

" Mg^{++} , Mn^{++}	45	33.1
" α -aminoadipic acid reductase	0	0
Plus isocitric acid dehydrogenase*	102	76.6
Minus inorganic labelled pyrophosphate, plus labelled orthophosphate	0	0

* Purified isocitric acid dehydrogenase (0.5 mgm.). Complete system consisted of (in μ moles) 2 adenosine triphosphate, 2 inorganic labelled pyrophosphate (2×10^6 c.p.m.) or ^{32}P i (10^6 c.p.m.), 6 DL- α -aminoadipic acid, 2 magnesium chloride, 0.5 glutathione, 0.18 manganese chloride, 10 potassium fluoride, 10 barbital buffer pH 7.4 and 0.4 mgm. of α -aminoadipic acid reductase, in a total volume of 1.0 ml. Incubation was for 10 min. at 37°.

acid reductase, together with a possible mechanism of α -aminoadipic acid reduction reaction.

The isolation of the enzyme and steps of the purification were identical with those of the previous communication¹ except that the enzyme was dialysed for 2½ hr. against demineralized water and then for 34 hr. at 0° against 0.1 M potassium chloride solution containing 0.01 M potassium bicarbonate. After dialysis the enzyme solution was centrifuged at 10⁴g for 10 min. and the supernatant was saved. Isocitric acid dehydrogenase was purified by the method of Kornberg and Pricer².

The α -aminoadipic acid-dependent exchange between labelled inorganic pyrophosphate and adenosine triphosphate catalysed by the enzyme was studied by Hoagland's method³. The reaction was stopped with 6 per cent perchloric acid. Adenosine triphosphate was separated from the labelled pyrophosphate and determined according to the method of Craine and Lipmann⁴.

Typical results are presented in Table 1. α -Aminoadipic acid reductase catalysed a rapid exchange of labelled inorganic pyrophosphate with the pyrophosphate moiety of adenosine triphosphate. The exchange reaction was dependent on the presence of α -aminoadipic acid and Mg^{++} . In contrast to the overall reduction reaction, no requirement for glutathione was observed, and monoiodoacetate also did not give any appreciable effect on the rate of the exchange reaction. This indicates that the reduction reaction of α -aminoadipic acid is separable into two coupled reactions. The exchange reaction occurred only with the intact pyrophosphate molecule without prior hydrolysis to orthophosphate. The exchange reaction was completely inhibited by versene and recovered by addition of Mg^{++} . The reaction occurred over a broad pH range of about 6–8 and was optimal at about pH 7.4. Of twelve amino-acids tested including homoglutamine, lysine, glutamic acid and aspartic acid, α -aminoadipic acid only was active in this system. It should be emphasized that homoglutamine, the δ -carboxyl group of which is blocked in the form of acid amide, was lacking in activity.

In the previous communication, we reported the formation and accumulation of a derivative of α -aminoadipic acid- δ -semialdehyde in the α -aminoadipic acid reduction system. In the subsequent experiments, it was found that under ultra-violet light the paper chromatogram of the α -aminoadipic acid- δ -semialdehyde derivative fraction showed one main spot (concomitant with other spots), the R_F (0.08–0.12, with n -butanol-acetic acid-water; 4.5 : 1 : 2 v/v) of which corresponds to that of the area occupied by

the colour reaction with p -dimethylaminobenzaldehyde⁵, and both are superimposable. The other spots appearing on the chromatogram may be attributed to the deteriorated products of the primary reduction product of α -aminoadipic acid, since highly labile and deterioration properties of the reduction product might be expected. When the reduction reaction was carried out in the presence of potassium fluoride (10^{-2} M), pyrophosphate was accumulated in the system. The reduction reaction was inhibited about 50 per cent of control by 5×10^{-4} M of adenosine-5'-phosphate, while pyrophosphate at higher concentrations than adenosine-5'-phosphate was only slightly inhibitory to the system, and the latter, on the other hand, had little effect on the exchange reaction.

These findings permit a tentative formulation of the process by which α -aminoadipic acid is reduced to its semialdehyde. First, α -aminoadipic acid reacts with adenosine triphosphate through the δ -carboxyl group splitting off pyrophosphate and forming possibly δ -adenyl- α -aminoadipic acid as an activated α -aminoadipic acid. δ -Adenyl- α -aminoadipic acid is then an obligatory participant in the reduction reaction, and the reactions can be written as follows:

These reactions would account for the strong inhibition of adenosine monophosphate to the reduction reaction of α -aminoadipic acid, as the result of adenosine monophosphate and δ -adenyl- α -aminoadipic acid competition for the enzyme at the reduction step (reaction 2). The above reactions would also account both for the α -aminoadipic acid-dependent exchange between pyrophosphate and adenosine triphosphate, and for the accumulation of a derivative of α -aminoadipic acid- δ -semialdehyde and pyrophosphate in the reduction system of α -aminoadipic acid. The primary reduction product of α -aminoadipic acid appearing in the 6 N hydrochloric acid eluate might be an adenosine-5'-phosphate derivative of α -aminoadipic acid- δ -semialdehyde (tentatively to be referred to as δ -adenyl- α -aminoadipic acid- δ -semialdehyde), which might equilibrate with the dehydrated form.

By assuming these structures, it is possible to account for the labile property of the primary reduction product toward heat treatment, resulting in the formation of Δ^1 -piperidine-6-carboxylic acid¹.

Details of this work will be published elsewhere.

Paper Chromatography and Paper Electrorheophoresis of Tuberculo-proteins

PAPER electrophoresis of proteins has on the whole proved to be a more satisfying means of separation than paper chromatography, owing to the physico-chemical properties of the proteins that make them rather unfit for the latter method^{1,2}. Nevertheless there do exist methods of paper chromatographic separation of, for example, enzymes, blood and serum proteins, mainly based on a kind of adsorption analysis, in addition to the more usual procedures of partition-, ion exchange- and adsorption-chromatography on columns.

Franklin *et al.*³ claimed to have made separations of sera into a great number of fractions by means of two-dimensional paper chromatography. Conditions and results of these procedures provoked severe criticism. Though inclined to be sceptical I, too, agreed with E. and M. Lederer¹ in their opinion on the possible value of these investigations and so undertook similar experiments. The method of two-dimensional chromatography with respectively 0.1 M sucrose and 0.1 M potassium sodium tartrate³, applied to my bovine tuberculin purified protein derivative, and some of its fractions⁴, produced strange irregular patterns of no practical value, though a certain reproducibility was observed. For practical purposes I then proceeded in the following way: 0.1 M sucrose in the first direction and 0.041 M acetic acid + 0.009 M sodium acetate in the second. The pH of this last-named buffer, being 4, is the isoelectric precipitation point of the C fraction under certain defined conditions⁵.

Fig. 1 shows that with my chromatography these conditions were rather well fulfilled.

The corresponding preparations from non-heated culture filtrates⁶ gave the same pictures; only the ratio $A+B/C$ was higher⁶ as expected and demonstrated by quantitative colorimetric measurement of the eluates. The patterns are in their entirety reproducible, but not in detail. So, for example, the $A+B$ spots vary in shape and show a division into two or more parts. I doubt if there can be attributed any meaning to this partition from the viewpoint of protein separation. How far we are dealing

Fig. 3. Electrorheophoresis of 0.05 ml. protein samples (50 mgm./ml.). The curves were obtained with a Zeiss scanner

Fig. 1. Two-dimensional chromatography at 4° C. for about 3 hr. in each direction. Circular spots of 0.02 ml. protein solution of about 50 mgm./ml. In between, drying in the cold, for example, with a fan. Staining of the heat-dried Whatman No. 1 sheets with 'Amidoschwarz 10B' (Bayer). Dimensions of the sheets, 11 in. × 11 in.

with artefacts remains to be investigated. My method, based on a previously known chemical separation and therefore somewhat dissatisfying like others of this kind⁷, can be used in comparing different tuberculin samples.

Among many other experiments only chromatography with pyridine/sucrose solutions, combined with electrophoresis in borate buffers, showed patterns of some reproducibility, though as yet not good enough for practical use.

The difficulties encountered in paper electrophoresis of heated tuberculo-proteins, the properties of which are apparently unfavourable for this kind of separation, have been mentioned before⁴. In this case the molecular weight of the C protein is twice the normal, while the A and B fractions consist probably of molecules smaller than when they do not originate from heat-sterilized culture media⁸, facts that may account for the greater separation troubles⁹. In trying to cancel unfavourable effects in paper

electrophoresis due to the above-mentioned protein properties, I found a method, based on the electrophoresis principle of Macheboeuf¹⁰, in which a rather vigorous evaporation-flow counteracts the electrophoretic movement of the proteins. The apparatus and results are shown in Figs. 2 and 3. A pH 8 buffer was used, consisting of 10 gm./l. boric acid, 0.5 gm./l. disodium salt of ethylene di-amino-tetraacetic acid, 0.05 ml./l. of 'Tween 80' and *tris* hydroxy methyl amino-methane so as to make the pH of the solution 8. Separations took place on Schleicher and Schüll paper No. 4032b *Mgl* at 7-9 V./cm. during 4-6 hr. at 24°C. For standardizing electrophoresis conditions and identification of the fractions obtained further investigations remain to be carried out.

Evidence for the Existence of Two Corticotrophin-releasing Factors, α and β

WE wish to report here the presence of two distinct peptides with corticotrophin-releasing factor activity in hog posterior pituitary extracts. All the separation methods as well as the bioassays for corticotrophin-releasing factor, adrenocorticotrophic hormone, vasopressin and melanocyte stimulating hormone have been described previously¹⁻⁶.

A single peak of basic peptides obtained by preparative chromatography on carboxymethylcellulose had as its main components lysine-vasopressin and α -melanocyte stimulating hormone³. This peak, which also contained all the corticotrophin-releasing factor activity, was distributed for 100 transfers in a system of *n*-butanol/0.03 *M* *p*-toluene sulphonic acid. Lysine-vasopressin ($K = 0.32$, 300 pressor U./mgm.) was well separated from the α -melanocyte stimulating hormone area ($K = 6.13 \times 10^7$ melanocyte stimulating hormone U./mgm., 0.2 pressor U./mgm.). The α -melanocyte stimulating hormone area contained corticotrophin-releasing factor activity, which could be separated from the α -melanocyte stimulating hormone on analytical scale carboxymethylcellulose columns. This corticotrophin-releasing factor activity was found to be due to a peptide or a group of peptides containing the amino-acids of α -melanocyte stimulating hormone⁷ plus threonine, alanine and leucine. The peptide with corticotrophin-releasing factor activity apparently related to α -melanocyte stimulating hormone, containing methionine as the sulphur amino-acid, has been designated α -corticotrophin-releasing factor.

Some inherent adrenocorticotrophic hormone activity of α -corticotrophin-releasing factor (<0.2 U./mgm.) and the presence of alanine and leucine support the concept that this molecule may serve as a biosynthetic precursor of adrenocorticotrophic hormone. The peptide obtained by Gros and Privat de Garilhe⁸ appears to be similar or identical to α -corticotrophin-releasing factor. Since the latter was active in releasing adrenocorticotrophic hormone only at relatively high levels of 2-3 μ gm. *in vivo* or 0.5 γ *in vitro*, this discrepancy in corticotrophin-releasing factor activities as compared with our previous results^{2-4,9} had to be explained. Similarly the amino-acid composition of α -corticotrophin-releasing factor closely resembling that of α -melanocyte stimulating hormone led us to believe that we were dealing, in α -corticotrophin-releasing factor, with a substance quite different from the one we had purified earlier¹⁻⁴, which appeared to be related to vasopressin.

The peak of pressor activity in the countercurrent distribution system was then carefully explored. It was possible to detect corticotrophin-releasing factor activity on the descending edge of the vasopressin peak after countercurrent distribution. A separation from vasopressin was achieved by paper partition chromatography². Corticotrophin-releasing factor activity was found to be due to a small peptide, apparently related to vasopressin, on the basis of preliminary amino-acid composition and chromatographic behaviour. This peptide, active at 0.05 γ *in vitro* or 0.1 γ *in vivo*, was designated β -corticotrophin-releasing factor. Additional support for the concept of two distinct corticotrophin-releasing factor molecules was provided by the detection of two corticotrophin-releasing factor active areas with different specific activities on an analytical scale column of carboxymethylcellulose. This was achieved under conditions in which the order of elution of vasopressin and α -melanocyte stimulating hormone is reversed³, the starting material being posterior pituitary concentrates³.

Since both α - and β -corticotrophin-releasing factor are very basic peptides, our results are not in agreement with the data of Royce and Sayers⁹. One of the two corticotrophin-releasing factor active areas obtained by these authors after chromatography of median eminence extracts on carboxymethylcellulose must be explained by the presence of an acidic component or more probably, according to our own results, by overloading of the column. In our work, results from preparative chromatography of median eminence extracts on carboxymethylcellulose have revealed the presence of only one corticotrophin-releasing factor active area, in the position occupied by basic peptides emerging just before vasopressin. Under the conditions used here it is likely that this corticotrophin-releasing factor activity in hypothalamic extracts was due to β -corticotrophin-releasing factor, although on a preparative scale carboxymethylcellulose column the presence of some α -corticotrophin-releasing factor cannot be eliminated with certainty.

In view of the discrepancy in the specific activities and preliminary amino-acid composition of the two substances, one might propose that β -corticotrophin-releasing factor is the true chemical mediator for release of adrenocorticotrophic hormone, whereas α -corticotrophin-releasing factor is an α -melanocyte stimulating hormone analogue, possibly a pre-

cursor in the biosynthesis of adrenocorticotrophic hormone.

Spontaneous Plasma Kinin Formation in Human Plasma collected during Labour

DEFICIENCY of substrate for induced plasma kinin production in the stored plasmas collected from women at the time of delivery has been shown¹. This substrate deficiency was not observed in normal plasma (that is, from non-parturient individuals) stored for long periods at -20°C ., or in plasma collected at time of delivery from women undergoing Caesarean section at term before the onset of labour.

In the present series of experiments the plasmas were collected as previously described¹; but, as soon as possible after their collection (5-25 min.), plasma aliquots were placed in polythene containers at 0°C ., and tested forthwith, in doses of 0.1-0.01 ml., on the isolated rat uterus in a 10 ml. bath. It was then found that plasmas collected from women in labour showed marked oxytocic activity, which increased further for $\frac{1}{2}$ -1 $\frac{1}{2}$ hr. This unusual activity was observed a short time before the onset of labour. The rapidity of its development increased throughout the first and second stages reaching, at its maximum, an activity equivalent to several units of oxytocin ('Syntocinon', Sandoz) per ml. plasma. It then declined, but was demonstrable for a variable period (usually 1-4 hr.) after completion of the third stage. These findings are in contradistinction to the negligible oxytocic activity which develops in normal plasma kept in polythene containers at 0°C . for 1 hr.²

The spontaneously produced oxytocic activity in parturition plasmas kept at 0°C . resembled that due to plasma kinin³. It rapidly disappeared when the temperature of the plasma was raised to 20°C . Conversely, the rate of disappearance of kinin added to plasma was markedly reduced when the plasma temperature was lowered from 20°C . to 0°C . This can be explained by the influence of temperature on plasma kininase. Since we have found the same

kininase activity in normal and parturition plasmas, we consider that the rapidly developing oxytocic power of the latter, at 0°C ., was almost certainly due to abnormally rapid formation.

The amount of spontaneous kinin formation in plasma samples collected at different stages of parturition was directly correlated with the degree of substrate depletion measured at these different stages¹.

We think it unlikely that plasmin was the enzyme responsible for the spontaneous production of oxytocic activity since the peak period for development of the latter in the plasma, and the subsequent depletion of kininogen, corresponds with the nadir of fibrinolytic activity reported in pregnancy plasma⁴. Moreover, normal plasma with high fibrinolytic activity (for example, after severe exercise or surgical operations) failed to develop a similar marked oxytocic activity. In addition, agents such as heparin (25 I.U./ml.) and ϵ -amino caproic acid (0.12 M), which inhibit plasmin, promoted the spontaneous kinin formation. These substances also potentiate kinin formation in normal plasma when it is exposed to glass, and this is known to be independent of the plasminogen-plasmin system^{5,6}.

The active oxytocic principle did not develop in parturition plasma to which the soya bean trypsin inhibitor (2 mgm./ml.) had been added. Like plasma kinin, it was extractable in boiling ethanol from active (that is, oxytocic) plasma kept at 0°C ., but not from control samples of the same plasma kept at room temperature, and the activity of the extracts was rapidly destroyed by a crude amino-peptidase (*E. coli*) preparation. It is our opinion that it is probably a polypeptide.

The oxytocic activity in plasma or extract, unlike oxytocin, was not rapidly destroyed by sodium thioglycollate, though the build-up of kinin in parturition plasma kept at 0°C . was inhibited by this agent. In these respects the spontaneous kinin production resembled that of kinin formed by exposure of human plasma to glass, and, to a certain extent, the formation of bradykinin by trypsin added to human pre-active plasma. Differences in dose-response relationships between the spontaneously arising kinin of parturition plasma and oxytocin, and the marked lack of tachyphylactic response of the uterus towards the former, also suggest that we were not dealing with oxytocin itself.

The increasing rapidity of development of the parturition kinin throughout labour, reaching its maximum at the end of the second stage, suggests that the oxytocic activity may be related to the increasingly powerful contractions observed in the human uterus up to this time. The source of the active enzyme producing this oxytocic activity is not at present known.

Isolation of Hyaluronate from Human Synovial Fluid by Zone Electrophoresis

LITTLE is known about the condition of hyaluronate in normal human synovial fluid because it is difficult to isolate the former in good yield by mild methods from small quantities of highly viscous fluid. Although hyaluronate can be completely precipitated from small amounts of synovial fluid by adding acetic acid or a complex cobalt salt, some degradation of hyaluronate may occur, and 50–60 per cent of the proteins of the fluid are co-precipitated in the mucin clot¹. Isolation of hyaluronate from synovial fluid by moving-boundary electrophoresis is feasible, for at pH 8.6 hyaluronate migrates toward the anode slightly ahead of albumin. In normal synovial fluid, one or two components that migrated ahead of albumin were found² but were not isolated for further study. Electrodeposition of pooled synovial fluids was carried out three times at pH 7.0 by Roseman *et al.*³, and hyaluronate was isolated in yields of 70 per cent or less, with a ratio mgm. protein/mgm. hyaluronate of 0.13, or about 11.5 per cent protein in the hyaluronate.

In the present work the use of zone electrophoresis permitted hyaluronate to be isolated from small quantities of viscous fluid and recovered for analysis. A weighed amount (about 1 gm.) of synovial fluid from apparently normal knee joints of deceased or living subjects was diluted to 5 gm. with a phosphate buffer (0.047 M, pH 6.5) and then dialysed for about 18 hr. at 2° C. against 500 ml. of an acetate buffer (0.087 M, $\Gamma/2 = 0.075$, pH 5.4) changed twice (10.2 gm. crystalline sodium acetate and 0.7 ml. glacial acetic acid diluted to 1 litre with distilled water that was also de-ionized). An aliquot (about 0.1 gm.) of the diluted and dialysed synovial fluid was analysed for hexuronic acid⁴. The protein content of diluted and dialysed normal synovial fluid is too low to interfere with this analysis. All the hexuronic acid measured is a component of hyaluronate, since testicular hyaluronidase hydrolyses and renders dialysable 95 per cent of the hexuronic acid of the fluid.

The remainder of the diluted and dialysed synovial fluid was applied to a 2½ in. long slit in a solid block (18 in. × 5 in. × ½ in.) of polyvinyl chloride ('Geon' resin No. 427 from B. F. Goodrich Chemical Co., Cleveland, Ohio). Electrophoresis was carried out in the acetate buffer at 2° C. either for 14 hr. at a voltage gradient of 8.7 V./cm., or for 21½ hr. at a gradient of 5.5 V./cm. The equipment and technique were modified from that used for zone electrophoresis of serum⁵.

After electrophoresis, strips of Whatman No. 1 filter paper were pressed on the wet block and were

Fig. 1. Electrophoresis of normal human synovial fluid in acetate buffer (pH 5.4) on a block of polyvinyl chloride for 20½ hr. at a gradient of 5.5 V./cm. Hyaluronate zone, segments 14–20; orosomucoid, segments 22–25; albumin forms the main component of segments 26–28

dried at 90° C. for 20 min. The paper strips were stained with bromphenol blue or toluidine blue to locate approximately the positions on the block of proteins and hyaluronate respectively. The block was cut into segments (½ in. wide × 3½ in. long) starting near the anodal end. Each segment was placed in a sintered glass (coarse) funnel and eluted with a total of 10 ml. of a buffer (0.01 M sodium bicarbonate, 0.05 M sodium chloride, pH 8.1) by applying air pressure to the funnel. The eluates were evaporated to dryness *in vacuo* and then dissolved in 2 ml. of de-ionized distilled water. Insoluble resin was removed by centrifugation. All the eluates were examined for protein by a modified Folin method. Each eluate containing hyaluronate was analysed for hexuronic acid. (Hexuronic acid × 2.5 = hyaluronate.)

At pH 5.4 hyaluronate migrated faster than most of the proteins of synovial fluid, but a small amount of protein was present in the hyaluronate zone (Fig. 1). Hyaluronate was recovered in a yield of 80–90 per cent (Table 1). Further results shown in Table 1 were obtained by pooling all the eluates containing hyaluronate and measuring hexuronic acid and protein (Red Cross Fraction 2 was used as the protein standard). These experiments were done only when the zone of hyaluronate and protein was completely separated from the rest of the proteins of synovial fluid, as shown in Fig. 1. The ratio mgm.

* Age of subjects from whom fluid was obtained.

† Part of this synovial fluid was also incubated with testicular hyaluronidase and zone electrophoresis was then carried out. Hyaluronate fragments were recovered in a yield of 80 per cent and the ratio mgm. protein/mgm. hyaluronate fragments was 0.018.

Fig. 2. Double gel diffusion in agar of pooled, concentrated eluates from normal synovial fluid after zone electrophoresis. A, Centre cup, anti- γ -globulin (absorbed with fraction V and a β -globulin fraction). 1, Fraction II, 0.2 per cent. 2, Hyaluronate zone (segments 14-20) from normal synovial fluid shown in Fig. 1. A faint, broad precipitin line formed near slowly diffusing antigen. Concentration of antibody was in excess. B, Centre cup, anti-fraction VI. Orosomucoid standard 0.025 per cent. 2, Fastest migrating protein component of normal serum isolated by zone electrophoresis at pH 5.4. 3, Protein (segments 22-25) from normal synovial fluid shown in Fig. 1. 4, Protein that migrated just behind hyaluronate zone isolated by zone electrophoresis of another normal synovial fluid. Precipitin lines formed by all antigens coalesced (reaction of identity). These experiments were carried out by Dr. L. Korngold.

protein/mgm. hyaluronate of the isolated hyaluronate was 0.02-0.12. Double-diffusion studies in agar showed that the protein in two samples (Table 1, 23 and 62) of isolated hyaluronate formed a precipitin line against anti- γ -globulin (Fig. 2). Neither orosomucoid nor albumin, which migrated just behind the hyaluronate zone, could be detected in these samples of hyaluronate by this immunological method.

Eluates containing the isolated hyaluronate from four synovial fluids (Table 1, 33, 38, 41, 59) were pooled, concentrated to a small volume and dialysed in distilled water to remove salts. After adding potassium acetate (1 per cent w/v) and 1 vol. of cold ethanol, part of the hyaluronate formed a rosy clot. Addition of two more volumes of ethanol resulted in a flocculent precipitate of more hyaluronate. Each precipitate was separately washed with ethanol and ether, and dried over phosphorus pentoxide in a vacuum. Analytical results are shown in Table 2. The hyaluronate obtained contained the lowest quantity of protein (4 per cent) yet reported when mild methods have been used for isolation. The calculated protein content of the hyaluronate obtained by three electrodepositions³ was 11.5 per cent; the isolation of protein-free hyaluronate was reported in a later abstract⁶, but analyses were not given. Ogston and Stanier, after 16 or more ultrafiltrations of bovine synovial fluid, isolated hyaluronate in the ultra-filter residue in what was called a firm complex with about 25 per cent protein, composed largely of α -globulins, with smaller amounts of β - and γ -globulins⁷. Ogston and Sherman recently found⁸ that 65

Table 2. ANALYSES OF HYALURONATE OBTAINED BY ZONE ELECTROPHORESIS OF NORMAL HUMAN SYNOVIAL FLUIDS

Eluates containing the isolated hyaluronate from four synovial fluids were pooled. On addition of 1 vol. of ethanol part of the hyaluronate was precipitated as a rosy clot; addition of two more volumes of ethanol caused a flocculent precipitate of hyaluronate. Each precipitate was separately dried and analysed

	Ethanol added	
	1 vol.	3 vol.
Yield (mgm.)	2.8	1.3
Hexosamine (per cent)	28.6	
Hexuronic acid (per cent)	31.6	34.2
Molar ratio $\frac{\text{hexosamine}}{\text{hexuronic acid}}$	0.98	
Nitrogen (per cent)	2.88	3.36
Molar ratio $\frac{\text{nitrogen}}{\text{hexosamine}}$	1.26	1.36
Protein (per cent)	2.47	4.53

per cent of the protein in the complex could be removed by proteolytic enzymes without altering the physical properties of the hyaluronate in solution. In the present work the finding of γ -globulin in the hyaluronate zone is unexpected and worth further study.

This work was supported by grant 24-5082 from the National Institute of Arthritis and Metabolic Diseases, and by the New York State Chapter, Arthritis and Rheumatism Foundation. We are grateful to Drs. H. Kunkel and E. Franklin for advice concerning zone electrophoresis; and to Dr. M. Schubert for helpful discussions.

Note added in proof. Further to identify protein in the isolated hyaluronate, rabbits were injected with this material in Freund's adjuvant. Antibodies to α_2 -globulin as well as to γ -globulin were detected by the tanned cell haemagglutination technique.

Inhibitor of the Cytochrome Oxidase of Unfertilized Sea Urchin Eggs

In a previous communication¹ the presence of an inhibitor of cytochrome oxidase in the unfertilized sea urchin egg was described. It was shown that its activity decreases considerably following fertilization, that it is a low-molecular compound, that it is heat- and alkali-labile and that its action is of a competitive type.

We wish to report here some further experiments aimed mainly at obtaining the inhibitor in a purified form and at finding out about its chemical nature and its mode of action.

Fig. 1 illustrates a typical experiment showing that the inhibitor (prepared as described by Maggio and Monroy¹) interferes with the oxidation of reduced cytochrome *c* by cytochrome oxidase (a preparation of mitochondrial membranes²). On the other hand, we have found that the reduction of cytochrome *c* is not inhibited. These results, taken together with the previous ones on the competitive type of the inhibition, suggest that the mechanism of the inhibition may be interference with the oxidation of cytochrome oxidase.

Most of our efforts have been directed towards the purification of the inhibitory substance. After several unsuccessful attempts, encouraging results have been obtained using columns of 'Ecteola' cellulose. Homogenates of jelly-free unfertilized eggs of *Paracentrotus lividus* in 0.05 M phosphate buffer at pH 7.2 were centrifuged at 12,000*g* for 15 min. in the cold and the supernatant centrifuged again at 105,000*g* for 1 hr. The final supernatant was dialysed overnight against distilled water and the dialysate

Fig. 1. Inhibition of the re-oxidation of cytochrome *c* by a crude preparation of the inhibitor (effluent from a 'Dowex-50' column, see ref. 1). The system contained in the final volume of 3.3 ml. of 0.1 *M* phosphate buffer pH 7.4, 2.78×10^{-5} *M* cytochrome *c*, 8.1×10^{-3} *M* sodium ascorbate, mitochondrial membranes from rat liver (0.1 ml. containing 0.1 mgm. protein). ●, control; ○, + 0.3 ml. of inhibitor; ▲, + 0.6 ml. of inhibitor. The re-oxidation of cytochrome *c* is indicated by the decrease of the absorbance at 550 $m\mu$.

containing the inhibitor was lyophilized. The dry material was dissolved in cold glass-distilled water to a final concentration of 0.04 *M* phosphate and the pH adjusted to 7.2. This solution was passed through an 'Ecteola' column prepared in phosphate buffer 0.04 *M*, pH 7.2. The unadsorbed material was collected, together with the first washing (carried out with 20 ml. of phosphate 0.04 *M*, pH 7.2), which was followed by a stepwise elution with 10 ml. portions of 0.04 *M* phosphate at pH 6.5, 6.0 and 5.0. The washing and the eluates were lyophilized, redissolved in distilled water to a final concentration of 0.08 *M*, and, after adjusting the pH to 7.2, assayed for the cytochrome oxidase inhibiting activity by the manometric technique, as already described¹. The results of two such experiments are given in Table 1. While in most cases the activity was present only in the pH 5.0 fraction, in others, as in Exp. 2, some activity was eluted also with the other fractions. We take this as an indication that our method of fractionation is not yet entirely satisfactory. No ninhydrin-positive spots appeared in the chromatograms of the pH 5.0 fraction and nitrogen determinations were also negative. Hence it may be concluded that the inhibitor is not a nitrogen-containing substance.

It has happened sometimes, especially during purification, either that an originally active preparation lost its activity in the course of purification,

Table 1. CYTOCHROME OXIDASE INHIBITING ACTIVITY OF THE FRACTIONS OBTAINED FROM AN 'ECTEOLO' COLUMN

	Exp. 1		Exp. 2	
	QO_2	Δ (per cent)	QO_2	Δ (per cent)
Control	441		404	
Washing			380	-5.95
Eluate pH 6.5			371	-8.20
Eluate pH 6.0	479	+ 8.6	320	-20.8
Eluate pH 5.0	284	-35.6	274	-32.2

Each Warburg vessel contained, in the final volume of 3.0 ml., 0.2 ml. of rat liver mitochondria, 0.2 ml. of cytochrome *c* 2.46×10^{-4} *M*, sodium ascorbate 30 μM , phosphate buffer 0.048 *M*, pH 7.4, sample of the inhibitor 0.6 ml. Values are expressed as $\mu l.$ oxygen/hr./mgm. of mitochondrial proteins (QO_2).

or that the preparations were inactive from the beginning. We have then tried to re-activate such inactive inhibitors and positive results have been obtained with reduced glutathione and cysteine. The former compound has given more constant results, evidently due to its greater stability at the neutral or slightly alkaline pH used in the manometric tests. When the re-activation was tried on the fractions obtained from the column, this was obtained only with the pH 5.0 fraction. The results of a typical experiment are illustrated in Table 2.

Table 2. RE-ACTIVATION BY REDUCED GLUTATHIONE 10^{-3} *M* FINAL CONCENTRATION. OTHER CONDITIONS AS IN TABLE 1

	QO_2	Δ (per cent)
Control mitochondria	548	
Mitochondria + glutathione	576	+ 5.1
Mitochondria + pH 5.0 eluate	590	+ 7.2
Mitochondria + pH 5.0 eluate + glutathione	474	-13.5

These results seem to suggest that thiol groups may be responsible for the inhibitory activity.

PHYSIOLOGY

Thyroid Function and Oxidative Phosphorylation in Cold-exposed Rats

THE presence of the thyroid gland appears to be necessary for prolonged survival of the cold-acclimatized rat^{1,2}. Rats in the cold also appear to turn over iodine-131 more rapidly than normal³⁻⁶, indicating a more rapid than normal accumulation of iodide and release of thyroid hormone. Since oxidative phosphorylation, a process thought by some⁷⁻¹⁰ to be regulated by the thyroid, has been noted to be partially uncoupled¹¹⁻¹³, as well as physically and biochemically more labile in the cold-acclimatized rat^{12,14}, we have investigated the alteration of mitochondrial function following thyroidectomy of cold-exposed and normal rats.

Rats used in these experiments were exposed to 0-2° C. for 4-5 weeks. Thyroids were removed surgically at this time, and three weeks were allowed for recovery. The completeness of thyroidectomy was ascertained by relative concentrations of labelled potassium iodide in the neck region versus leg musculature 5-7 days after isotope injection. Ratios between 1 and 2 were accepted as indicating complete thyroidectomy. Controls were maintained at 25° C. Twice-washed liver mitochondria were prepared essentially according to Schneider and Hogeboom¹⁵ in 0.25 *M* sucrose. Oxidation was measured by Warburg manometry and phosphate esterification according to the isotope distribution method of Lindberg and Ernster¹⁶. The lability of the mitochondrial oxida-

Fig. 1. Loss of phosphorylative ability of mitochondria during ageing

tive phosphorylation system was measured according to Ernster and Löw¹⁷. Lability of phosphorylative ability is expressed as the 'Ageing Index^P', which is equal to the time of ageing, in minutes, required to depress the phosphorylative capacity to a value half-way between maximal and minimal phosphorylation. Values of the statistical quantity *t* were obtained by a small sample, paired comparison method¹⁸, and *P* derived from standard probability tables.

No difference was observed in the efficiency of oxidative phosphorylation (P/O) between preparations from control and thyroidectomized rats maintained at 25° C. (Table 1). On the other hand, the same mitochondrial suspensions showed a greater resistance to ageing on the part of the thyroidectomized preparation, this phenomenon being reflected in the difference in 'Ageing Index^P'. A comparison of the P/O ratios of mitochondria from intact animals, one group maintained for 4-5 weeks at 0-2° C., the other at 25° C., confirms previously published data on the lowering of the phosphorylative efficiency¹¹ and the 'Ageing Index¹²' of the cold-exposed group. Thyroidectomy of the cold-exposed rat results in mitochondrial preparations with normal phosphorylative efficiency as well as a normal 'Ageing Index^P'. When preparations from rats maintained at 25° C. and 0-2° C., and which have been thyroidectomized are compared, the P/O ratios are normal while the 'Ageing Index^P' of the 25° C. thyroidectomized preparation is greatly increased. Ageing curves from a representative experiment involving the four preparations discussed above are presented in Fig. 1. The 'Ageing Indices^P' were calculated from such data.

These data indicate that: (1) The stability of the oxidative phosphorylation system may be in part regulated by thyroid hormone. (2) Under conditions where the P/O ratio does not reflect thyroid regulation

Table 1. THE EFFECT OF THYROIDECTOMY ON THE P/O RATIO AND THE RESPONSE TO AGEING OF LIVER MITOCHONDRIA FROM CONTROL AND 4-5-WEEK COLD-EXPOSED RATS

No. of exp.	Environmental temperature	P/O		<i>P</i>	'Ageing index ^P '		<i>P</i>
		Intact	Athyroid		Intact	Athyroid

7	25° C.		1.84	0.51		>21.4	0.01
	0-2° C.		1.80			13.6	

Each Warburg or Erlenmeyer flask contained: Mitochondria from 1/20th rat liver, 50 μ moles dipotassium hydrogen phosphate; 150 μ moles potassium chloride; 4.3 μ moles adenylic acid; 60 μ moles glucose; 125 μ moles sucrose; 30 μ moles succinate; 7.5 μ moles magnesium sulphate; and 330 *KM* units hexokinase; final pH, 7.4. 20 ml. reaction volume, 20 min. incubation, air gas phase. Oxygen consumption extrapolated for initial 5 min. (ref. 17).

(hypothyroidism) an indication of regulation may be observed by the determination of the 'Ageing Index^P'. (3) The rat is not wholly dependent on an intact thyroid to regulate uncoupling of oxidative phosphorylation and 'Ageing Index^P' since the P/O ratio and 'Ageing Index^P' of thyroidectomized preparations are returned to normal in the cold-exposed animal by thyroidectomy, but not to the cold-exposed level, indicating a control in addition to the thyroid state. This type of control may reside in the tissue itself and may consist of an autoregulatory device on the tissue-level of organization.

This work was accomplished under U.S. Air Force Contract 41(657) 145, monitored by the Alaskan Air Command, Arctic Aeromedical Laboratory.

Abolition by 2:4-Dinitrophenol of the Protective Effect of Succinate and Adenine Nucleotides on the Onset of the Thyroxine-induced Swelling of Liver Mitochondria

THYROXINE is known^{1,2} to induce a rapid and extensive swelling of freshly isolated rat and mouse liver mitochondria suspended in a deficient medium. It has been reported recently³ that succinate (5×10^{-4} M) and adenine nucleotides (10^{-5} M) protect against the onset of this swelling for a certain time, but not against the extent of swelling ultimately reached. The former effect was very pronounced with liver mitochondria from rats maintained on a polished-rice diet for 3-12 months. These experiments were carried out with inbred albino rats of the strain *R-Amsterdam* and *F₂(C57 Black × CBA)* hybrid mice. It has now been found that the protective effect is weaker when liver mitochondria from several inbred strains of mice (*CBA*, *C57 Black* and *O₂₆-Amsterdam*) or from a partly inbred strain

(LE) of piebald rats are used than with the particles isolated from the livers of the former animals, all animals being maintained on the standard laboratory diet. The order of activity of the nucleotides appeared to be: adenosine di- > tri- > > -monophosphate, the latter being in many cases scarcely effective, if at all. Evidence has been obtained³ that the adenine nucleotides, added in a sufficiently low concentration as to make any chelating effect unlikely, were especially active when added in conjunction with succinate. The conclusion was, therefore, drawn that the protective effect of the latter compounds on the onset of the thyroxine-induced swelling (that is, the retardation thereof) was mediated by promoting the process of oxidative phosphorylation under the adverse conditions of the deficient medium. This view has now been substantiated by the following results, which may also shed some further light on the anomalous effects of 2:4-dinitrophenol (DNP) on the swelling of isolated liver mitochondria.

DNP has been shown^{1,2} to abolish completely the spontaneous or thyroxine-induced swelling of liver mitochondria suspended in deficient medium, but to induce swelling when oxidizable substrate is also present⁴⁻⁶. When taking into account that electron transport in the respiratory chain is required for swelling⁴⁻⁶ and that DNP may inhibit respiration⁹, the conclusion can be drawn (compare ref. 6) that DNP abolishes the spontaneous or thyroxine-induced swelling by inhibiting the electron transport from intramitochondrial substrates, and thus prevents swelling. Since there is also evidence⁹ that added oxidizable substrates may counteract the inhibitory effect of DNP on respiration, the above anomaly may be more apparent than real. In this connexion it should be noted, when comparing the concentrations of DNP used in manometric and swelling experiments, that the mitochondria in the latter case are much more diluted than in the former.

Figs. 1a and b represent two experiments in which effects of DNP (5×10^{-5} and 2.5×10^{-5} M, respectively) on the pattern of swelling of R-rat liver mitochondria in the presence of thyroxine, succinate and adenosine diphosphate (ADP) were studied, using the same technique as described previously³. In both cases DNP not only inhibited the thyroxine-induced swelling of the particles observed in the absence of added substrate, but also abolished the protective effects of succinate and succinate plus ADP on the onset of the thyroxine-induced swelling. In the first experiment with 5×10^{-5} M, but not in the second with 2.5×10^{-5} M DNP, the rate of swelling in the presence of thyroxine (3×10^{-5} M), DNP and succinate (and ADP) was much less pronounced than that observed in the absence of DNP once the protective effect of succinate (and ADP) was overcome. This difference may be accounted for by assuming that 5×10^{-5} M, in contrast to 2.5×10^{-5} M DNP, still inhibited the electron transport from succinate to a certain extent. If so, it might be expected that, when the oxidation of the latter is prevented by malonate (5×10^{-3} M), the inhibitory effect of DNP on the electron transport, now stemming mainly from the endogenous substrates, may predominate again and thus abolish the swelling effect of thyroxine. Fig. 1b shows the latter prediction to be true for the low concentration of DNP.

The finding that the protective effect of succinate and adenine nucleotide on the onset of the thyroxine-induced swelling is abolished by either malonate or

Figs. 1, a and b. Effect of 2:4-dinitrophenol and/or malonate on the thyroxine-induced swelling of fresh rat liver mitochondria incubated in the presence of succinate (and adenosine diphosphate). 2:4-Dinitrophenol, 5×10^{-5} M in exp. a and 2.5×10^{-5} M in exp. b; DL-thyroxine, 3×10^{-5} M, present in each flask; succinate, 5×10^{-4} M; adenosine diphosphate, 1.5×10^{-3} M; malonate, 5×10^{-3} M. Note that the curves indicated by small circles in Fig. 1b represent the situation as found in the absence and presence of adenosine diphosphate

DNP indicates that the former effect is dependent on both the oxidation of succinate and the accompanying phosphorylation.

The *in vitro* swelling action of thyroxine on liver mitochondria has been shown¹⁰ to represent an acceleration of a process which the mitochondria are already inherently capable of undergoing spontaneously; a similar conclusion has been drawn previously¹¹ in regard to the loss of diphosphopyridine nucleotide from isolated mitochondria, the action of thyroxine being then described as representing an acceleration of the structural and biochemical labilization of the particles such as is manifested after their ageing. The correspondence between spontaneous and thyroxine-induced swelling was further substantiated by the finding³ that both processes responded in a similar manner to succinate and the adenine nucleotides, the response being determined by the type of mitochondrial preparation (fresh; intact or damaged by washing¹² at 0° C.; aged at 0° and 37° C.). Since for swelling to occur electron transport along the respiratory chain is required, and since intact mitochondria capable of phosphorylating do not swell, a labilizing change in the biochemical structure of isolated liver mitochondria suspended in deficient medium, leading to uncoupling, has been postulated as necessarily preceding mitochondrial swelling. Thyroxine appears to accelerate the latter change, which has been identified^{8,12,13}, albeit tenta-

tively, as caused by or to involve a loss of adenine nucleotides from the particles in the deficient medium lacking magnesium.

Accelerated Recovery from Reserpine Depression by Monoamine Oxidase Inhibitors

It is generally accepted that pretreatment with a strong monoamine oxidase inhibitor, for example iproniazid, antagonizes the behavioural depression induced by reserpine¹. The converse experiment in which the inhibitor is given after reserpine in an attempt to terminate the depression apparently has not been as well explored; at least two papers, however, have reported failures to obtain such a reversal². In the present experiments, chronically reserpinized animals were under observation for extended periods (weeks) before and after treatment with iproniazid or β -phenylisopropylhydrazine (JB 516). The conditioning techniques used provided an objective assay of behaviour changes. Under these conditions, the behavioural depression produced by reserpine was clearly alleviated by a single injection of a monoamine oxidase inhibitor, although the onset of the arousal lagged about a day after the dosing.

Five hungry male rats, maintained at 80 per cent of their weight when feeding *ad libitum*, were trained to obtain a drop of sweetened condensed milk by pressing a lever in the wall of a small chamber. Not every press was rewarded; eligibility for reinforcement was programmed randomly and occurred, on the average, once a minute. This variable-interval reinforcement schedule produced a steady, high response-rate throughout the 1-hr. experimental sessions, and thus furnished a dependable behavioural base-line for the measurement of drug effects.

Administration of reserpine phosphate (0.2 mgm./kgm. base intraperitoneally) was begun after the lever-pressing rates had become stabilized. Injections were made immediately after every experimental session, even on days when other drugs were given. Behavioural tests were not run at week-ends, but the reserpine was injected every day once the series was started.

Fig. 1. Daily response output throughout the experiment for the five rats. Abscissa, daily 1-hr. test sessions; markers indicate successive days; ordinate, total number of lever responses; each marker denotes 400 responses. Reserpine was administered immediately after each test session on week-days and also on week-ends (indicated by crosses) when behavioural tests were not made. The first three reserpine injections were 0.5 mgm./kgm., and all succeeding ones, 0.2 mgm./kgm. A single dose of iproniazid or JB 516 was injected half an hour before the start of the test session indicated.

After several reserpine injections with no apparent effect, the rates of response declined rapidly. When the rates were about 10 per cent or less of the pre-reserpine levels, the monoamine oxidase inhibitors were administered. Three of the animals were injected with iproniazid phosphate (100 mgm./kgm. intraperitoneally) and two with β -phenylisopropylhydrazine hydrochloride (2.5 mgm./kgm. intraperitoneally) half an hour before the start of the test period. Reserpine was injected as usual after this period, and daily for several weeks thereafter.

Fig. 1 gives the daily lever-pressing rates for the five animals throughout the course of the experiment. With the exception of rat 70 (which probably required a larger dose of iproniazid), substantial recovery from the reserpine inhibition may be observed on the second or third day after the dosing with the inhibitor; the reversal lasted about one month. Without the protection of an inhibitor, a reserpine series of this sort is usually lethal; the animals stop eating and seem to be less resistant to disease.

Also interesting was the observation that the monoamine oxidase inhibitors actually increased the suppression of lever-pressing for many hours immediately after the dosing. In Fig. 1 it may be seen that on the day that the inhibitor was given, the response output of all animals approximated zero. Such absolute suppression of the lever-pressing rate within half an hour after an iproniazid or JB 516 injection has been observed invariably in more than twenty experiments. These doses of iproniazid and JB 516

have no obvious effects on the lever-pressing performance of rats not treated with reserpine.

These findings bear upon theories that attribute the behavioural effects of reserpine to the changes this drug brings about in the levels of endogenous brain monoamines; the serotonin and catechol amine in the brain are both depleted extensively and both have been taken to be implicated^{1,3}.

The present observation of a delayed reserpine reversal by the monoamine oxidase inhibitors follows the time-course of recovery of norepinephrine in the brain more closely than that of serotonin. Spector *et al.* have reported that the level of serotonin in the brain in reserpinized rabbits rose almost to normal within 2 hr. after an injection of JB 516, while the level of norepinephrine remained virtually unchanged⁴. During this time of recovered serotonin-levels in the present experiments, the inhibition of lever-pressing behaviour was not reversed, but actually was increased. The present observation that the peak of the recovery was delayed for a number of days corresponds with a similarly delayed increase in the norepinephrine-level in the brains of rabbits treated with monoamine oxidase inhibitors⁴. Also favouring an important role for the catechol amines are the findings that amphetamine, a close structural and pharmacological relative of the catechol amines, and cocaine, a known potentiator of catechol amine activity, both potently and rapidly reversed the behavioural inhibition produced by reserpine. Reversal of reserpine-induced depression of behaviour with cocaine has been observed by J. Seifter and one of us (L. S.) in experiments at the Wyeth Institute for Medical Research.

Electrophoretic Mobilities of Normal and Regenerating Liver Cells

By measuring the electrophoretic mobility of cells, Ambrose, James and Lowick¹ have demonstrated that the average charge density of neoplastic kidney and liver cells is almost double that of the homologous normal cells.

It was further shown^{2,3} that the increase in the negative charge density of tumour cells is due to a gradual alteration of surface properties in direct relation to the degree of malignancy.

These observations gave rise to the question as to whether the increased charge density of neoplastic cells is specifically characteristic of malignancy, or could perhaps be considered as one of the manifestations of normal growth.

Fig. 1. Electrophoretic mobilities of single liver cells. Cells from normal liver show a mean mobility of 1.000 ± 0.015 . Cells from regenerative liver 24 hr. after partial hepatectomy 1.257 ± 0.021 S.E.

In an attempt to shed light on this problem, the electrophoretic mobility of regenerating liver cells was compared with that of the homologous non-regenerating cells.

Cell suspensions of adult rat liver were prepared by perfusing the liver with 0.05 M ethylenediamine tetraacetic acid slightly homogenized in a loose-fitting Potter-Elvehjem glass homogenizer⁴ and washed several times with phosphate-buffered saline⁵. This procedure yielded a rich suspension of liver cells. For electrophoretic measurements the cells were transferred to Sørensen's phosphate buffer M/15 (pH 7.4; ionic strength 0.174) and measured by the Northrop-Kunitz electrophoretic cell on a horizontal plane⁶. 100 cells, at least, were measured for each experiment. Erythrocytes served as internal control, and accordingly only animals in which the erythrocyte mobility was in the range of 1.21–1.27 $\mu/\text{sec.}/\text{V.}/\text{cm.}$ were used.

The measurements were carried out on coded samples so that the observer was unaware of the origin of the cells at the time of measurement.

Fig. 1 shows an increase by an average of 25 per cent in the mobility of the cells 24 hr. after partial hepatectomy, thus indicating the increased negative charge density of the regenerating liver cells.

When the changes in charge density of the cells during the regenerative process were followed up, an increase in mobility could already be observed at 6 hr. after the operation. The mobility was still high after 48 hr. However, in measurements taken after a considerable delay of 20 days, it was found that the cell mobility had returned to the normal level.

These experiments would indicate that the increased charge density of cells is also a manifestation of a normal growth process. It may be therefore that the growth associated with malignancy may be the cause of the increased charge density changes previously described^{1,2} rather than a property specific to malignant cells.

A detailed account of this work will be published elsewhere.

HÆMATOLOGY

Separation of Reticulocytes by means of Multi-Layer Centrifugation

RETICULOCYTES regarded as the youngest erythrocytes in the circulating blood have particular properties such as respiration^{1,2}, biosynthesis of haem *in vitro*³, electrophoretic mobility and osmotic resistance⁴ different from those of mature erythrocytes. Separation of reticulocytes in a pure and physiological state seems necessary in studying their properties and functions⁵.

We succeeded in separating reticulocytes by means of a multi-layer centrifugation with a gum acacia solution. The separating procedures are similar to those of leucocytes and bone marrow cells^{6,7} reported previously. The technique depends on the difference in densities between reticulocytes and mature erythrocytes. Separating media with various degrees of specific gravity are prepared immediately before the experiment by diluting a stock solution with physiological saline solution. The stock solution is prepared as follows: about 30 ml. of distilled water is put into a flask, to which about 30–32 gm. of gum acacia powder is added and stirred with a glass rod. The stirring is continued while the flask is being put in a water-bath kept at 80–90° C. Then water is added slowly up to about 90 ml. After the powder is dissolved, it is centrifuged at 1,000*g* for 20 min. The supernate is diluted with distilled water to a density of 1.090 at 15° C. The density is measured by a hydrometer which covers the range 1.060–1.120 in steps of 0.001 unit. As this solution is hypotonic to blood cells, sodium chloride is added to keep the solution isotonic with blood cells—usually about 0.2 per cent. The pH of this solution is adjusted to 7.4 by adding a few drops of a saturated sodium hydroxide solution.

The stock solution can be stored for several weeks in a tightly closed container kept in a cold room. The proper dilution of the stock solution to secure desired densities for the separation of reticulocytes can be calculated from the following formula:

$$X = \frac{1.090}{D - 1} \times A$$

where *X* is volume of physiological saline solution to be added, *A* is volume of stock solution, *D* is the density desired.

Fig. 1. Layered solutions before centrifugation

Usually two solutions *A* and *B* are used for separation; *A* with a specific gravity of 1.068–1.078 according to the preliminary test and *B* is 1.050 (15° C.). Each specific gravity desired should be determined by a preliminary test with blood cells, because there are individual and seasonal variations in density of reticulocyte.

Reticulocytosis is caused in adult rabbits weighing 2.5–3.0 kgm. by repeated bleeding or administration of phenylhydrazine; thus 10 ml. of blood per kgm. body-weight is withdrawn daily from the ear vein or by heart puncture until the reticulocyte count reaches about 30 per cent; or 0.3 ml. of a 2.5 per cent phenylhydrazine hydrochloride solution per kgm. body-weight is injected subcutaneously daily until the reticulocyte count reaches about 50 per cent. The blood of the rabbit with reticulocytosis is withdrawn from the ear vein in measured amounts of 3.8 per cent sodium citrate or neparin solution. The blood is washed with physiological saline solution and then centrifuged at 1,000*g* for 20 min. The supernate and buffy coat (a concentrated leucocyte and platelet layer) are pipetted off.

The sedimented red blood cells are suspended in a two- or three-fold volume of physiological saline

Fig. 2. Separated blood cells in a centrifuge tube. 1, Fibrin layer with leucocytes and platelets; 2, reticulocyte layer; 3, mature erythrocyte layer

Fig. 3. Separated reticulocytes (brilliant cresyl blue staining). ($\times 800$)

solution and used for a multi-layer centrifugation. All the procedures are carried out in a cold room kept at $2^{\circ}\text{--}0^{\circ}\text{C}$.

Two ml. of solution A is poured into a centrifuge tube (13 mm. in inner diameter, 10 ml. in capacity) and 2 ml. of solution B is layered over the A carefully along the inner wall of the tube with a pipette. Then about 3 ml. of the blood sample is put on B (Fig. 1). The layered solutions are centrifuged at 4,000–5,500*g* for 15 min. A Marusan electric centrifuge (horizontal head) is employed: conical head centrifuges do not seem convenient for a multi-layer centrifugation. After centrifugation the following three layers are formed in a centrifuge tube (Fig. 2): from the top to the bottom, (1) fibrin lying with a few leucocytes and platelets; (2) reticulocyte (immature erythrocyte) layer; (3) mature erythrocyte layer. The reticulocytes float on the boundary of solutions A and B forming a stratum, so that they can be easily collected with a pipette. The reticulocytes thus prepared show a 95–100 per cent purity in separation (Fig. 3). Their functions and properties will be discussed in the *Japanese Journal of Physiology*.

Human Embryo Haemoglobin

ALTHOUGH evidence of the presence of a second fetal haemoglobin in young human fetuses is accumulating^{1–6}, uncertainty still seems to prevail in some quarters as to the existence of this embryonic haemoglobin⁷. The following report of a paper-electrophoretic study of the haemoglobins of six 6–12-week-old and five 15–18-week-old human fetuses may therefore be of some interest.

Haemolysates containing about 10 per cent haemoglobin were prepared from citrated cord blood follow-

Fig. 1. Electrophoretic pattern of haemoglobins. 1, 2 and 3, normal adult haemoglobin; 4, haemoglobin from 12-week-old fetus; 5, normal full-term new-born infant. Arrow indicates direction of migration

Fig. 2. Electrophoretic pattern of haemoglobins. 1, Mixture of haemoglobin from 12-week-old fetus and full-term new-born infant; 2 and 4, haemoglobin from 12-week-old fetuses; 3, normal full-term new-born infant. Arrow indicates direction of migration

ing the technique of Singer *et al.* The spots were run on Whatman No. 1 filter paper for 20–21 hr. in barbital buffer at a pH of 8.6 and at approximately 0.1 ionic strength.

As can be seen from Table 1 and Figs. 1 and 2, the migration of the haemoglobins in the group of 7–12-week-old fetuses was definitely slower than the migration of the haemoglobins in the group of 15–18-week-old fetuses and of full-term infants and adult controls. In relation to the migration of normal adult haemoglobin the mean ratio foetal haemoglobin : adult haemoglobin was 0.86 in the group of small fetuses and 0.98 in the group of 15–18-week-old fetuses.

After migration a mixture of haemoglobins from a 12-week-old fetus and a full-term new-born infant showed signs of separation (Fig. 2).

It seems reasonable to assume that the haemoglobin in the blood of the 7–12-week-old fetuses described here is identical with the embryonic

haemoglobin of a 10-week-old human foetus which Halbrecht and Klibansky identified by means of paper electrophoresis. The "primitive type P" embryonic haemoglobin described by Allison² and the early embryonic haemoglobin distinguished through alkali denaturation by Drescher and Künzer¹ may well be identical with the haemoglobin of the small foetuses reported here.

The migration pattern of the haemoglobins of the 15-18-week-old foetuses differed significantly from the haemoglobins of the 7-12-week-old group. The mobility of the haemoglobins of the older group of foetuses showed but small differences as compared with the haemoglobin of normal full-term infants.

From the results of this investigation it was thus possible to distinguish a human embryonic haemoglobin from a group of 7-12-week-old foetuses, which, on paper electrophoresis under the conditions described, showed a mobility definitely slower than that of the haemoglobin of normal full-term infants. The mobility of the haemoglobins of the group of 15-18-week-old foetuses did not differ significantly from that of normal full-term infants.

These findings support the view³ that the haemoglobin in the erythrocytes derived from the mesoblastic tissue during early embryonic life is of a different type from the haemoglobin of hepatic and medullary origin. If this holds true, most of the haemoglobin of mesoblastic type is replaced by haemoglobin of hepatic origin in the course of 15-18 weeks of foetal life.

I am indebted to the Sigrid Jusélius Foundation for a grant towards the cost of this investigation.

PATHOLOGY

Leucocytic Emigration from Inflamed Capillaries

THE precise manner in which margination and emigration of leucocytes occur in acute inflammation has not been elucidated despite numerous careful studies with the light microscope. Utilizing electron microscopy we have observed the emigration of leucocytes from capillaries in areas of acute inflammation in dog pancreas. Capillary endothelial cells react to injury by forming intra-luminal finger-like projections of cytoplasm. These projections insinuate themselves around, and envelop, adjacent leucocytes, and, in this manner, draw the latter into the capillary wall (Fig. 1). This intramural localization of leucocytes is equivalent to 'margination' as seen by light microscopy and would appear to occur by a process similar to that of phagocytosis. The leucocytes are then extruded through the antiluminal border of the endothelial cell where they are separated from the extravascular space only by the basement membrane

Fig. 1. Electron photomicrograph of an inflamed capillary in which leucocytes (L) are surrounded by endothelial cytoplasmic processes (P). Lumen of capillary (CL), endothelial cell (EC), basement membrane (BM), extravascular space (ES). ($\times$ c. 4,670)

of the endothelial cell. After separation of leucocyte and endothelial cell by as much as 300 Å, new basement membrane forms between them and is continuous with the old. Simultaneously old basement membrane adjacent to the leucocyte becomes smudged and frayed and gradually melts away, releasing the leucocyte into the extravascular space.

Only rarely are interruptions seen in the continuity of either endothelial cell or basement membrane during the passage of leucocytes through them. In most instances, both endothelial cell and basement membrane are continuous and are re-formed behind the leucocyte before either is breached ahead of it. That the process is highly selective is demonstrated by the fact that segmented leucocytes are involved predominantly. The nature of this selectivity was not determined in the present work; it may be related to humoral factors acting on either the leucocyte or the endothelium. Agents which affect the degree or extent of inflammatory exudation may act on the endothelial cell.

The exact processes of margination and emigration described here may not occur in all species and for all inflammatory stimuli. Preliminary observations suggest that species variations may exist. Under the conditions of the experiment described here, however, the endothelial cell appears to play a very active part in these processes. Full details of this work will be published in the *American Journal of Pathology*.

Blood Corticotrophin in Cushing's Syndrome

PREVIOUS work on the level of blood corticotrophin in cases of Cushing's syndrome has been scanty and has not involved a full-scale bioassay of concentrated extracts used at sufficiently high dose-levels. Some of the early work on this subject was reviewed by Loraine¹ and semiquantitative values for four Cushing's patients have been given by Clayton².

From our experiments, values are given for the corticotrophin content of blood from two patients with Cushing's syndrome and from normal and hypertensive subjects.

Corticotrophin was extracted from large volumes of blood (500–1,000 ml.), collected between 10 and 11 a.m. The blood was run directly into glacial acetic acid to prevent possible enzymic destruction of the hormone³. In order to concentrate it for bioassay the corticotrophin was extracted by adsorption on oxycellulose followed by elution with 0.1 N hydrochloric acid by Astwood's method⁴ as modified for blood by Sydnor and Sayers⁵. The latter obtained an 85 per cent recovery of corticotrophin added to hypophysectomized rat blood. In our experiments, the eluate was stirred with moist 'De-acidite FF' resin (carbonate form), sufficient being added to bring the pH to 2.7. The solution was then freeze-dried, stored dry over phosphorus pentoxide at 4° C. and was re-dissolved in 0.9 per cent saline, acidified with a trace of 0.01 N hydrochloric acid, for intravenous injection into rats.

The blood concentrates were assayed by their action in depleting adrenal ascorbic acid in hydrocortisone-treated rats^{6,7}. Our assays involved the use of 30 rats and compared the effect of three dose-levels of the blood concentrates with three dose-levels (0.13, 0.40, 1.2 mU.) [1 milliunit (1 mU.) = 1/1,000 I.U.] of the 2nd International Standard for corticotrophin. The highest dose of the concentrate was equivalent to at least 50 ml. of blood. The accuracy was satisfactory for a bioassay method, average limits of error calculated at the 5 per cent level being 58–165 per cent. Results are given in Table 1.

Table 1. CORTICOTROPHIN CONTENT OF HUMAN BLOOD

Type of patient	Sex and age (yr.)	Volume of blood concentrated (ml.)	Potency of blood concentrate in rat assay	Limits of error expressed as percentage of the potency†	Blood corticotrophin mU./100 ml. blood
Normal*	I { 1 M 30	1,080	0.77	43–131	0.71
	1 F 34				
	1 F 37	1,000	0.58	43–232	0.71
	1 M 35				
	II { 1 M 40				
Hypertensive	M 51	1,000	0.59	55–183	0.72
Cushing's case 1	F 38	750	1.31	74–135	2.16
Cushing's case 2	M 44	450	0.81	74–136	1.80

* Blood was pooled from 3 and 2 individuals.

† Calculated at 5 per cent level.

‡ 1 mU. = 1/1,000 I.U.

In normal subjects, Sydnor *et al.*⁸ and Paris *et al.*¹⁰ believed from their experimental work that the corticotrophin content of blood was less than 0.5 mU./100 ml. Levels of 30–200 mU./100 ml. reported by Bornstein *et al.*¹¹ have been criticized by Loraine¹, who suggested that these levels would have been accompanied by clinical features of adrenocortical hyperfunction.

It seems unlikely that the high values for our two Cushing's patients are caused by hypertension (see Table 1). Clearly more cases should be studied in greater detail, with values before and after treatment correlated with the pathology of the adrenal and pituitary glands.

This research programme has been supported by a grant to one of us (A. R. C.) from the Scottish Hospital Endowments Research Trust.

RADIOBIOLOGY

A Sexual Difference in the Concentration of Iodine-131 by the Submaxillary Gland of Mice

A SEXUAL dimorphism in the submaxillary gland of mice has been described by Lacassagne¹. In the male the secretory tubuli are more developed than in the female. This difference has since been reported as depending on endocrine glands^{2–4}.

Human saliva concentrates iodine-131 (ref. 5). Since this demonstration, experiments have been carried out on the iodine-concentrating capacity of salivary glands. Logothetopoulos and Myant⁶ established this fact for the submaxillary gland of mice and it was shown that the degree of concentration is related to the strain of the animals⁷. Radioautographic studies⁸ led to the conclusion that the secretory tubuli are the structures of the gland which concentrate iodine.

Table 1

Total iodine-131 per mgm. of submaxillary tissue Total iodine-131 per mgm. of blood				
Males		Females		P
No. of animals	Mean ± S.E.	No. of animals	Mean ± S.E.	
61	5.25 ± 0.31	40	3.89 ± 0.32	< 0.01

In the present communication we report our findings on the sexual difference in the iodine-concentrating capacity of submaxillary glands of mice.

Sixty-one male and forty female C3H mice were injected intraperitoneally with 5 µc. of carrier-free solution of iodine-131. 1 hr. later the submaxillary gland was removed and blood collected under ether anaesthesia. The glands and blood were weighed and radioactivity measured in a well counter. The ratio:

$$\frac{\text{total } ^{131}\text{I per mgm. submaxillary tissue}}{\text{total } ^{131}\text{I per mgm. blood}}$$

was taken as a measure of the degree to which submaxillary tissue is able to concentrate iodine.

The results are given in Table 1.

These results show that there is a sexual difference in the capacity to concentrate iodine by the submaxillary gland of mice.

Uptake of Magnesium-28 by the Skeleton of a Sheep

In order to find the cause of hypomagnesaemia in adult ruminants, it is necessary to have a better understanding of the mechanism controlling magnesium-levels in blood and particularly the relationship between bone and blood magnesium. Bone from cows suffering from hypomagnesaemia showed no depletion of magnesium¹, and this has led to the theory that the lability of bone magnesium is much reduced in adult animals². There are no figures in the literature, however, for either the amount or the rate of mobilization of skeletal magnesium in adult ruminants, but such data can be obtained from work on the uptake of radioactive magnesium by bone. Because of the short half-life of magnesium-28, only that part of the bone magnesium which is rapidly exchanged with the magnesium of plasma and other body fluids can be measured.

After six days on a constant diet of grass nuts containing 1.2 gm. of magnesium, a five-year-old Greyface wether, weighing about 65 kgm., was given 40–60 μ c. carrier-free magnesium-28 as the chloride into the jugular vein. 10 hr. later, immediately after sampling the blood, the sheep was killed by exsanguination under nembutal anaesthesia, and duplicate samples of bone, free so far as possible from blood and bone marrow, were taken from various parts of the skeleton and their radioactivity determined the same day in a well-type scintillation counter.

The values obtained for the calcium-magnesium ratio and specific activity of the samples of selected bones are given in Table 1. The specific activities are expressed both as the percentage of dose $\times 10^2$ per mgm. of total magnesium and as the percentage of the specific activity of the plasma, the latter being a measure of the proportion of bone magnesium which has exchanged with the magnesium of body fluids during the 10-hr. period.

A marked variation in specific activity from bone to bone was observed and was greater in regions of rapid bone metabolism than in compact bone. Thus

Table 1. RATIO OF CALCIUM TO MAGNESIUM IN THE SELECTED BONES AND THEIR UPTAKE OF MAGNESIUM-28 AT 10 HR. AFTER INTRAVENOUS ADMINISTRATION

Bone	Calcium/magnesium	Specific activity (percentage of dose) ($\times 10^2$ per mgm. magnesium)	Specific activity (as percentages of specific activity of plasma)
Femur shaft	57	0.048	0.86
Femur epiphysis	52	0.130	2.3
Rib shaft	56	0.079	1.4
Rib sternal end	46	0.129	2.3
Lumbar vertebra	46	0.099	1.7

the sternal end of the rib and the epiphysis of the femur showed the greatest exchange and the femur shaft the lowest.

The over-all percentage of bone magnesium in equilibrium with the magnesium in the body fluids was low; the values for the samples of individual bones ranged from 0.86 to 2.3 per cent. The limiting factor may be the exchange-rate itself or the amount of bone magnesium which is available for exchange. It is interesting to note that the variation in specific activity of individual bones was in the same order as the degree of magnesium depletion in the corresponding bones from magnesium-depleted calves³.

There are no analytical figures in the literature for the magnesium content of the skeleton of either adult cattle or sheep. Estimates can be made from the calcium content of the skeleton of dairy cows⁴ and sheep, and the calcium-magnesium ratio in bone. The calculated values for cows range from 90 to 160 gm. depending on the size of the animal, and for sheep from 8 to 10 gm.; the figures for sheep are based on only three analyses. If the reserves of bone magnesium are assumed to be the same as the percentage of bone magnesium which has later reached equilibrium with the magnesium of body fluids, namely, 2 per cent, the skeleton of dairy cows contains 1.8–3 gm. of magnesium which can be released to satisfy physiological needs, that is, enough for 3–5 gallons of milk. In the case of sheep, the reserves (160–200 mgm.) are equivalent to the endogenous faecal loss for 1 day⁵. The lactating animal may be more efficient in mobilizing bone magnesium than the non-lactating animal, since the resorption of bone mineral to provide the calcium necessary for lactation will also release magnesium⁶. This effect, however, will be small because of the wide ratio of calcium to magnesium in bone and the fact that the release of calcium from bone is small, for example, less than 20 gm. a day for dairy cows⁷.

My thanks are due to Dr. J. R. Greening and Mr. P. Tothill, Department of Medical Physics, University of Edinburgh, for valuable help.

BIOLOGY

Effect of Chelating Agents on Plasmodium Formation by the True Slime Mould, *Didymium nigripes*

SPORES of *Didymium nigripes*, a true slime mould, germinate to liberate myxamœbæ which multiply by binary fission. After a period of exponential growth, the uninucleate myxamœbæ fuse to form macroscopic, multinucleate veins of rhythmically flowing protoplasm called plasmodia. Following an indefinite period of growth, the plasmodia differentiate into spore-containing fruiting bodies. Kerr and Sussman¹ grew *D. nigripes* in monoxenic culture with *Aerobacter aerogenes* on a dilute glucose-peptone-yeast extract agar medium buffered with phosphate at pH 6.2 (hereafter called GPY/5). All stages of the life-cycle were regularly reproduced in less than 7 days. When 0.25 per cent (w/v) brucine was added to the GPY/5, plasmodia did not appear. Instead, the myxamœbæ remained indefinitely as such and could be sub-cultured as amœbæ. The myxamœbæ quickly formed plasmodia when harvested from the GPY/5-brucine plates and washed by differential centrifugation.

The morphogenesis of uninucleate myxamœbæ to multinucleate plasmodia is one of the most interesting, but least understood, stages in the life-cycle of the true slime moulds. According to Cadman² and Ross³, plasmodium formation involves the pair-wise fusion of myxamœbæ as gametes to form zygotes. Presumably the zygotes develop into plasmodia by growth, nuclear division, and fusion with other zygotes. Since an understanding of this morphogenesis is an essential prerequisite to studies on the genetic life-cycle, and to studies of heterokaryosis and nuclear-cytoplasmic interrelationships in the plasmodium, an elucidation of its mechanics has been undertaken. The mechanism by which brucine inhibits plasmodium formation was studied in the hope that it would yield information on the normal process of plasmodium formation.

One possible action of brucine might be to stimulate the bacterial associate to produce a metabolite which in turn would inhibit plasmodium formation. This possibility was tested by growing myxamœbæ on GPY/5-brucine with a variety of bacterial associates, including *Escherichia coli*, *Sarcina lutea*, *Pseudomonas fluorescens* and *Aerobacter aerogenes*. Plasmodia did not appear in any instance. It therefore seemed probable that brucine was acting directly on the myxamœbæ rather than via the bacterial associate.

Several lines of evidence indicated that brucine might be inhibiting plasmodium formation by chelating with ions in the medium. First, although the medium used was saturated by 0.1 per cent (w/v) brucine, the inhibitory action of brucine became more and more complete as its concentration was raised to 0.25 per cent. This might be expected if brucine were acting as a chelating agent, but not if it were acting as a metabolic inhibitor. Second, brucine inhibits the formation of plasmodia rather than plasmodia themselves, for if plasmodia are sub-cultured on GPY/5-brucine, they grow and fruit normally. Third, the density of myxamœbæ profoundly influences the number of plasmodia which they form. Even in the absence of brucine, plasmodium formation was delayed when the myxamœbæ

quickly reached a high density. Plasmodia appeared in greatest number when the myxamœbæ exhausted their bacterial food supply while still at a relatively low density. Brucine-inhibition was complete only when the myxamœbæ covered the entire plate at high density before exhausting their food supply; when myxamœbæ were plated clonally on GPY/5-brucine, occasional plasmodia appeared.

As a result of these observations, experiments were devised to test the hypothesis that multivalent cations are essential to plasmodium formation. The results are reported in Table 1. Chelating agents were added to GPY/5 media which were spread with spores of *D. nigripes* and 0.3 ml. of a broth culture of *A. aerogenes*. In each case the pH was adjusted to 6.0-6.5. The plates were incubated at 22° C. for 4 days and then scored for growth of myxamœbæ and appearance of plasmodia. Tetrasodium ethylenediamine tetraacetic acid at 10⁻³ M completely prevented the formation of plasmodia, even when the spores gave rise to clones. Either 10⁻³ M Mn⁺⁺ or 10⁻³ M Fe⁺⁺ reversed the inhibition of ethylenediamine tetraacetic acid to permit numbers of plasmodia to form. None of the other ions tested was effective. Other chelating agents, including sodium citrate, were also effective in inhibiting plasmodium formation.

Table 1. THE GROWTH OF MYXAMŒBÆ AND APPEARANCE OF PLASMODIA ON GPY/5 MEDIA TO WHICH VARIOUS AGENTS HAD BEEN ADDED

Addition	Amœbæ	Plasmodia
Control	+++	+++
0.25 per cent (w/v) brucine	+++	0
0.1 M Sodium citrate	++	0
10 ⁻³ M Ethylenediamine tetraacetate acid	++	0
5 × 10 ⁻⁴ M Ethylenediamine tetraacetic acid	+++	+
10 ⁻³ M Ethylenediamine tetraacetic acid		
+ 10 ⁻³ M calcium chloride	++	0
+ 10 ⁻³ M strontium chloride	++	0
+ 10 ⁻³ M magnesium chloride	++	0
+ 10 ⁻³ M manganese chloride	++	++
+ 10 ⁻³ M ferrous chloride	++	++

The experimental results thus confirm the hypothesis that multivalent cations are necessary for plasmodium formation. A likely mode of action of brucine is as a chelating agent, removing these ions from the medium.

The development of a technique which will measure plasmodium formation in a quantitative manner is in progress. These experiments will be reported elsewhere.

Effect of Extracts from Fucoids in promoting Settlement of Epiphytic Polyzoa

In a previous communication¹ it was suggested that the simple ciliated larvæ of some species of sedentary organisms might respond to qualitative differences in bacterial films formed on surfaces immersed in the sea, as was suggested by Wilson to explain the behaviour of the larvæ of *Ophelia bicornis* Savigny².

Table 1. SETTLEMENT OF *Alcyonidium polyoum* ON TREATED INERT SURFACES

Type of surface	No. settled in experiment (1)	(2)	(3)	Total No. of settled larvae
Unfilmed surface	5	3	3	11
Surface filmed by standing in sea water for 24 hr.	1	4*	0	5
Surface similarly filmed and treated with extract of <i>Fucus serratus</i> in distilled water	90	46	26†	162

* Treated with distilled water for 2 hr. after filming.

† Extract of *Fucus* made up in sea water.Table 2. RATIO OF NUMBER OF LARVÆ OF *Alcyonidium polyoum* SETTLED ON FILMS TREATED WITH ALGAL EXTRACTS (NA) IN COMPARISON WITH SETTLEMENT ON FILMS TREATED WITH *F. serratus* (NF)

Algal extract of :	Ratio NA/NF	
<i>Fucus serratus</i>	1.00	} Probably effective
<i>Fucus vesiculosus</i>	1.04	
<i>Ascophyllum nodosum</i>	1.72	
<i>Pelvetia canaliculata</i>	0.63	
<i>Fucus spiralis</i>	0.09	} Not effective
<i>Laminaria digitata</i>	0.25	
<i>Ulva lactuca</i>	0.04	
<i>Gigartina stellata</i>	0.00	
Control	0.22	

Some recent experiments with the larvæ of the polyzoan *Alcyonidium polyoum* (Hassall) have confirmed this. This species normally occurs on the fronds of *Fucus serratus* L., and its larvæ settle preferentially on fronds of this and related fucoids when offered a choice of different algal fronds³. When these larvæ were placed in a glass vessel and offered small rectangular pieces of inert material for settlement, as described in a previous communication¹, they tended to avoid filmed surfaces, as did the larvæ of *Bugula flabellata*, though they did not settle very readily on unfilmed surfaces. However, when the filmed surfaces were treated beforehand with an extract of *Fucus serratus* they become very attractive to the larvæ, as can be seen from Table 1. Extracts of other algae were tested in the same way, but only certain species were regularly effective in promoting settlement. It can be seen from Table 2 that those species which promoted settlement all belonged to the Fucaceae. Of the most attractive sources, *Fucus serratus* L., *Fucus vesiculosus* L. and *Ascophyllum nodosum* (L.) le Jol, only *F. serratus* normally bears colonies of *Alcyonidium*. Perhaps the other two fucoids occur too high up the shore, or do not liberate the active principle on to the surface of the thallus. Similar results have also been obtained using the larvæ of the closely related polyzoan *Flustrellidra hispida* (Fabricius).

The settlement of these larvæ seems not to be due to any physical property of the film, such as its thickness, since, in the absence of *Fucus* extract, filmed surfaces are not attractive. However, when unfilmed surfaces were briefly treated with the extracts they did not attract the larvæ strongly; only filmed panels could be made artificially favourable for settlement.

The bacterial film is therefore necessary to promote good settlement, but it must be treated with the extract. The simplest hypothesis is that the active principle is transferred to the film, and, as it diffuses out, it attracts the larvæ. Other mechanisms which may lead to larval recognition are possible, however; for example, the existing bacterial film may modify substances present in the *Fucus* extract, or the bacterial flora of the film itself may be altered in the presence of an extract of *Fucus*. The mechanism by which the larvæ of *Alcyonidium polyoum* and *Flustrellidra hispida* recognize the treated film is now being investigated, while similar phenomena are

being sought in the settlement behaviour of other marine larvæ.

Sex Hormones as a Possible Factor influencing the Level of Parasitization in Frogs

LARGE numbers of frogs (*Rana temporaria*) have been examined for helminth parasites during the period 1956-60. On analysing the results of these investigations, it was found that the level of parasitization in male frogs during and immediately before the breeding season was considerably higher than that in females. This difference between the levels of parasitization in the two sexes was particularly marked in the case of the trematodes, *Polystoma integerrimum* and *Gorgoderina vitelliloba*, the nematode, *Rhabdias bufonis*, and the acanthocephalan, *Acanthocephalus ranae*. After the breeding season, the difference became less marked. This is evident from Table 1, which is based on the results obtained by examining approximately 500 frogs from a single locality, over a period of four years.

Table 1. LEVELS OF PARASITIZATION OF MALE AND FEMALE FROGS DURING AND OUTSIDE THE BREEDING SEASON

Species of parasite	Percentage of frogs parasitized during January and February		Percentage of frogs parasitized during April and May	
	Males	Females	Males	Females
Trematodes				
<i>Polystoma integerrimum</i>	14.0	8.1	16.1	17.0
<i>Gorgoderina vitelliloba</i>	10.2	5.3	12.8	7.6
<i>Dolichosaccus rastellus</i>	8.9	10.2	5.3	6.2
<i>Haplometra cylindracea</i>	49.6	41.8	53.0	44.4
Nematodes				
<i>Rhabdias bufonis</i>	52.3	29.4	47.8	37.4
<i>Oscarioeruzia filiformis</i>	71.6	82.3	76.9	74.2
<i>Cosmocerca ornata</i>	86.3	94.1	88.4	92.3
Acanthocephala				
<i>Acanthocephalus ranae</i>	13.4	8.0	22.5	24.0

Similar, although less conclusive, results have been obtained by Markov¹ and Mazurmovich².

The difference in parasitization-levels of male and female frogs, well marked in the breeding season and much less well marked at a time of the year when the gonads have suffered regression, may be explained by assuming that the female sex hormones depress the level of parasitization in some way or other. In order to test this particular hypothesis we took fifty male frogs from a population known to be heavily parasitized with helminths, and injected half of them with oestradiol benzoate (B.P.) in 20 per cent ethyl oleate and 80 per cent arachis oil. The other half were regarded as controls. The experimental series were given 0.5 mgm. of oestradiol benzoate in 0.1 mgm. doses over a period of 12 days. At the end of three weeks both the experimental and control frogs were killed and examined for helminths.

Table 2. COMPARISON OF PARASITIZATION-LEVELS IN MALE FROGS TREATED WITH OESTRADIOL AND UNTREATED FROGS

Species of parasite	Percentage of control frogs parasitized	Percentage of experimental frogs parasitized
Trematodes		
<i>Polystoma integerrimum</i>	16	4
<i>Gorgoderina vitelliloba</i>	24	12
<i>Dolichosaccus rastellus</i>	12	0
<i>Haplometra cylindracea</i>	56	40
Nematodes		
<i>Rhabdias bufonis</i>	64	32
<i>Oswaldocruzia filiformis</i>	80	72
<i>Cosmocerca ornata</i>	90	72
Acanthocephala		
<i>Acanthocephalus ranae</i>	20	8

The results of this examination are given in Table 2.

The results of these preliminary experiments suggest that the presence of the female hormone, oestradiol, in the tissues and fluids of the host does lead to a depression of the level of parasitization by helminths. We propose to investigate this phenomenon in more detail.

Mobility of Barnacles

If a young barnacle is removed from a surface the remains of the antennal suckers, marking the point at which the individual cemented itself as a cypris larva, may sometimes be found near the centre of its base. It has generally been assumed that this point of basal attachment is fixed. The position selected by the barnacle, when a larva, would then always be included within the outline of its base, though not necessarily at the centre, for if growth were not radially symmetrical the original point of attachment might become eccentric.

Recent experiments have been carried out in which the growth of operculate barnacles has been followed after they have settled on transparent plates. These observations show quite clearly that such animals possess a limited mobility when subjected to lateral pressure. If one side of a young colony is cleared of settlement and kept bare, the individuals forming the free edge of the colony will be pushed outwards by the growth of the rest. This pressure, exerted over a period of several months, can displace the outermost individuals a few centimetres from their original position. Fig. 1 shows how a young individual can be moved through several times its own diameter during the first six months of life. Evidently the cement layer between the hypodermis and the solid surface must slowly be sheared as it allows the shell and membranous base to glide along. The advancing edge of the base can form new adhesions to the substratum in the same way that it does during the expansion of the base in normal growth. Rotation of the barnacle in response to currents probably occurs also in the same manner¹. Mobility has been observed both on smooth and on uneven surfaces.

Balanus balanoides, in common with other barnacles, has very strong powers of adhesion, so that when a number of individuals of about equal size

Fig. 1. Illustration of the movement of an individual *Balanus balanoides* (L.) which had settled at a distance of 2.4 cm. from the edge of a flat plate and was subjected to lateral pressure from other individuals growing above it (not shown). The ordinate gives the distance from the edge of the plate of the carinal and rostral ends of the base of the barnacle, the distance separating the lines representing its basal diameter. The abscissa gives the time which elapsed after settlement. By September the individual illustrated had begun to be forced over the edge of the plate

come in contact their bases remain attached to the solid surface and their sides become pressed together. Continued growth is then possible only upwards, unless the peripheral individuals can be slid outwards, when limited expansion of the whole colony may occur under its own two-dimensional pressure.

When the individuals which come into contact are not of the same age or do not belong to the same species, the result may be quite different. One specimen, usually the older, remains firmly attached, while the other is gradually displaced upwards on to the advancing shell plates of the former. This process can be readily observed when later settlements of *Elminius modestus* insinuate themselves among fast-growing spat of *Balanus balanoides*. The former are so completely squeezed out that they may come to project above the general level and can be detached by a gentle blow. If such individuals survive, their elevated position has some advantages, allowing more rapid growth and earlier maturity², and tending in the end to cause the underlying individuals to become silted up and smothered.

The ability to adhere strongly to a surface, but at the same time to retain sufficient mobility to move a short distance or to readjust themselves to alterations in the shape of the substratum, has two obvious advantages. It allows barnacles to grow on such surfaces as the shells of other animals, where there are slow relative movements or a gradual expansion of the whole area, without the danger of losing their adhesion. It also allows them, provided that the original settlement was sufficiently heavy, to expand into nearby bare spaces on a solid surface which were not, for some reason, initially colonized.

Most barnacles, within their normal geographical range, produce a superabundance of planktonic larvae, which settle in greater numbers than is necessary for survival. Consequently the factor which chiefly limits the size of populations is shortage of settling space. Each species must therefore, so far as possible, occupy all the surface suitable to it and exclude competing organisms. It is in this respect that the faculty of limited mobility is of such importance. Without it a colony of barnacles would be able to occupy only a small area around each of the positions initially selected by the cyprids, and

competing organisms would be quite free to settle afterwards in any of the spaces left unoccupied. Without such mobility young individuals growing among larger ones would be easily lifted off or crushed as the older ones crowded them in; this indeed may sometimes happen². The limited degree of sliding and adjustment possessed by barnacles therefore confers an advantage both to established populations, which are able to expand over any available space, and also to invading populations of new spat, which may in consequence be able to form a second tier of individuals using their competitors as an alternative, though mobile, substratum. The outcome of such a struggle between species depends not only on settlement pattern, population density and relative growth-rates, but also on the forces operating between the growing edge of the shell of each species and the substratum with which they are both in contact.

Mechanism of Change in Permeability in Living Membranes

AN important feature of many excitable cells is that their permeability to ions and even to large molecules such as aldolase depends on the potential difference across the cellular membrane¹. Thus, in nerve fibres a depolarization leads to a transitory increase in sodium permeability (P_{Na}), often followed by a slower development of an increase in potassium permeability (P_K). More recent studies of skeletal^{2,3} and cardiac (Carmeliet, E., and Weidmann, S., personal communication) muscle have demonstrated an opposite relation between P_K and membrane potential that has been designated 'anomalous rectification'. The purpose of this communication is to point out the possibility that the mechanism of these changes in permeability may be related to that recently proposed on the basis of monomolecular film studies of drugs known to affect the ionic permeability of natural membranes⁴⁻⁶. This mechanism is based on recently demonstrated physico-chemical principles and is susceptible to experimental test.

Agents such as local anaesthetics, designated as 'stabilizers', decrease the permeability of living membranes or depress their ability to undergo the rapid increase in permeability during excitation^{1,6}. They interact with monolayers of lipoidal molecules (for example, stearic acid) and thereby add their own bulk to the films; thus, molecular packing is increased, as reflected by a rise in surface pressure⁶⁻⁹. Conversely, compounds called 'labilizers' or 'unstabilizers', such as certain veratrum alkaloids, increase membrane permeability^{1,6}. These gradually remove the lipoidal molecules from the monomolecular films and hence reduce packing and surface pressure^{4,5}. It has been proposed from such observations and others that the degree of packing of membrane molecules surrounding a site of ion passage (for

example, an intermolecular space) is related inversely to (a) the ease of ion transport, and especially (b) to the ability of ion transfer to increase during excitation^{1,5,6}. The concept of changes in surface pressure through effects in the region adjacent to the locus of ion penetration focuses attention on membrane organization, which must be mesomorphic, that is, intermediate to a liquid and a solid¹⁰. Previous research has suggested this type of structure⁶; our recent work also suggests this, for the antagonistic effects of stabilizers and labilizers became apparent in the monolayers when the films are compressed to a condition intermediate to that of a liquid and solid⁵.

The work on drugs has led to emphasis on electrostatic and van der Waals interactions between the membrane and extrinsic molecules as the basis for changes in packing and in permeability. The possibility of such changes with membrane potential arises if the natural membranes contain lipophilic (hydrophobic) cations and anions at low concentration. Guastalla *et al.*¹¹ have already shown that relatively weak electrical gradients (V./cm.) can govern the accumulation of such ions at an oil-water interface, the speed of the process depending on the intensity of the applied field. Natural membranes, with a thickness of the order of 100 Å., have across them a 'resting potential' of about 100 mV. and hence an electric field, E , of 100,000 V./cm.; the inner boundary is normally negative to the exterior⁶.

Because of their nature, the lipophilic ions would not leave the membrane readily; therefore they would be distributed by the field as shown diagrammatically in Fig. 1A. The sketch on the left indicates only the ions capable of interacting with membrane molecules in the regions of sodium transfer, that on the right only those able to affect potassium transport. A_1 represents a small anion, perhaps with several charges, C a large cation with fewer charges, and A_2 an anion comparable in bulk and in number of charges to C . One more assumption is inherent in the model, namely, that only the outermost interface, M , possesses the mesomorphic state required for the permeability changes. The deeper region of the membrane is regarded as essentially fluid, thereby serving as a reservoir of lipophilic ions without contributing directly to the permeability changes. Experimental evidence for a superficial layer as the basis of permeability change in living membranes has recently been presented by Shanes and Berman¹², who also direct attention to other indications for this in the literature. The concentrations of the ions on the inner boundary of the interface regulate their degree of interaction with M .

Fig. 1B indicates an intermediate stage in the redistribution of the hydrophobic ions during a sudden depolarization of the membrane. A_1 , by virtue of size and charge, responds most rapidly to the alteration in E . As it moves out of M , P_{Na} increases. If the depolarization is sustained, as shown in the lowermost part of Fig. 1, C becomes more uniformly distributed and so enters M and reduces P_{Na} again. Such a secondary decrease in P_{Na} is well known and has been designated 'inactivation'. Finally, as A_2 leaves M , P_K increases. If, in addition to or instead of A_2 , cations were available comparable to C but more effective and able to enter the regions of potassium transport, then instead of the more familiar increase in P_K (and membrane conductance) with depolarization, that is, delayed rectification, a decrease would be obtained, that is, anomalous

Fig. 1. Hypothetical representation of the distribution of lipophilic cations and anions in a resting, normally polarized excitable membrane (A) and during two successive periods of a moderate depolarization. M is an outer mesomorphic region susceptible to change in permeability by interaction with drugs or with the lipophilic anions (A_1 , removal of which increases P_{Na} , and A_2 , removal of which increases P_K) and cations (C, entry of which causes inactivation, that is, a secondary decrease in P_{Na}). The negative sites in M are molecular groups that contribute to cation selectivity; they are shown as partly occupied by calcium in the normally polarized cell.

rectification. From this point of view, then, anomalous rectification is similar to the inactivation process for sodium, but apparently more effective inasmuch as permeability to potassium is lowered below the resting level. However, this difference in the inactivation processes might be merely a reflexion of a deficit in A_2 , a deficit which makes P_K at rest comparable to P_{Na} after A_1 has been partly removed. S. Weidmann's observation (personal communication) that potassium depolarization produces relatively little increase in the membrane conductance of Purkinje fibres appears in keeping with this.

It would be premature to contend that all changes in permeability can be ascribed to one principle. For example, it is possible that at least part of the increase in permeabilities during depolarization is a consequence of removal of calcium ions from superficial sites concerned with ion passage¹³. Such removal could increase permeability by allowing the monovalent ions to penetrate at these points; in addition, it is possible that calcium removal exposes adjacent negative groups of neighbouring molecules in the membrane, which are thereby driven apart to admit sodium and potassium ions and perhaps large molecules as well. In keeping with these proposals, lowering of pH also accomplishes a reduction in ion permeability⁶. Note, however, another possible role for calcium (and hydrogen) ions in Fig. 1. By neutralizing negative groups of the membrane

molecules in M, calcium could reduce the repulsion of anions and so enhance the entry of A_1 and A_2 into M, thereby lowering the permeability to sodium and potassium; concurrently, the attraction for cations would be reduced, thereby decreasing the entry of C into M and hence suppressing inactivation. This provides an electrostatic basis for the similarity in respect of their effects on permeabilities and on inactivation^{14,15}.

It is necessary to set up working models employing the principles that have been outlined to determine to what extent the kinetics of changes in permeability in living systems can be duplicated. A possible test of the validity of the proposed hypothesis would be to determine whether the effects of various lipophilic ions, for example, tetraethylammonium and tetrabutylammonium, which have been striking in some excitable cells^{16,17}, give evidence of being modified in a predictable manner by alterations in membrane potential.

Colchi-Autotetraploidy in *Adiantum capillus-veneris*

FERNS are well known for possessing polyploid complexes, but we do not know of any instance where Howard and Manton's¹ method has been used for analysis of their genome relations and elucidation of their nature of polyploidy. The primary reason for this appears to be the difficulties involved in raising autotetraploids in ferns. So far the standard practice has been to raise such strains by apospory². Manton³ alone made a meiotic analysis of the autopolyploid series in *Osmunda regalis* L. following this method and found reasonably high degree of multivalents.

The aposporous method of raising autopolyploids has certain inherent limitations in that it is laborious, time-consuming and above all it is uncertain. On the other hand, colchicine treatment is the most sure method available at present for inducing polyploidy. However, so far there has been a solitary attempt by Panigrahi⁴, who applied colchicine to the young embryos of *Cyclosorus repandulus* (v.A.v.R.) Ching

at the three-leaved stage, but could only obtain a sectorial chimera as evidenced by root tip smears while no fronds were borne on it. We have treated with colchicine the rhizomes of a few locally available ferns. Besides easy manipulation, the rhizome treatment gives quick results and eliminates the long time that is usually required for the sporophytes to reach maturity in case of spore, sporeling and embryo treatments. Of the three methods tried (immersion in aqueous solution of colchicine, lanolin paste and injections) we find the immersion in 0.5 per cent solution for nearly 48 hr. to be uniformly successful. The rhizomes were not defoliated because otherwise the first leaves produced would be sterile and also the rhizomes usually die after treatment when defoliated. The present account deals with the results on *Adiantum capillus-veneris* L. Here the new fronds start appearing within about three weeks after treatment. A morphological comparison with the controls treated similarly with distilled water revealed that autotetraploids, though smaller in size, show the usual *gigas* characters (thickness of rachis and lamina, stomatal size).

During meiosis the controls show invariably 30 bivalents (Fig. 1). The autotetraploids possess quadrivalents and bivalents. An analysis of ten exceptionally clear cells reveals that the number of quadrivalents ranges from 13 to 10 and the bivalents from 34 to 40. The average associations are $12\text{IV} + 36\text{II}$ (Fig. 2). The quadrivalents are in the form of rings or chains and possess almost completely terminalized chiasmata at diakinesis. The high degree of terminalization may also augment the normal disjunction during anaphases. In one case two bivalents showed early disjunction. Meiosis is perfectly normal and apparently normal spores result. In *Osmunda regalis*³ the percentage of quadrivalents per cell is nearly 66, while in the present case it is about 40, and trivalents are absent. The difference may be due to the smaller size of the chromosomes in the latter.

As indicated above, the spores are well filled and apparently normal. Sixty-four spores result in each sporangium. Interesting enough is the presence among them of about 3–5 per cent spores with bilateral symmetry, while the rule for the species and the genus is tetrahedral. Perhaps this may be due to the colchicine action. It is pertinent to mention here that Mehra and Loyal⁴ have observed another aberration, namely, branched rhizoids, being caused by colchicine action in the sporelings of *Goniopteris prolifera* Roxb. The change in symmetry of the spores is not due to the polyploid condition, because no such aberration has been found in any of the polyploid ferns discovered so far in Nature.

Fig. 1. Diakinesis in spore-mother-cell of diploid *Adiantum capillus-veneris*, $n = 30$. ($\times 1,000$)

Fig. 2. Diakinesis in spore-mother-cell of autotetraploid *Adiantum capillus-veneris*, showing $13\text{IV} + 34\text{II}$. ($\times 600$)

The present findings reveal that the rhizome treatment has obvious advantages over the uncertain method of apospory. Here in the meristem there is a single apical cell, the products of which give rise to the leaf and root primordia. Hence once the apical cell is rendered polyploid, all the subsequent fronds will naturally be autopolyploids, some of which will be fertile. The resulting spores should normally yield diploid gametophytes which can be used for crossing with natural tetraploids.

The occurrence of perfectly normal disjunction and well-filled and apparently normal spores by the autotetraploid in *Adiantum capillus-veneris* is rather important. The reason for this may lie in the fact that the present species is diploid throughout its range, and that in the genus there already exist potentialities for polyploidy up to the hexaploid⁵ (apogamous) level. Furthermore, the heterozygous nature of this horticultural fern is an additional point in favour. These are the two important points that are usually taken into consideration before embarking on a programme of induced autopolyploidy.

Apart from assessing the role of autopolyploidy in the evolution of ferns, the autopolyploids will also be useful in producing autotriploids from which trisomic lines for genetic studies may be raised. Their use in biosystematic studies of the fern polyploid complexes is of course unquestioned. The details of this work will appear elsewhere.

We are indebted to Prof. P. N. Mehra for advice, and to Dr. T. N. Khoshoo for criticism.

MICROBIOLOGY

Alleged Transformation of Yeast

CRUDE preparations of deoxyribonucleic acid from one yeast strain, called the donor, sometimes appear to confer fermentation properties of the cell on a second strain, the acceptor, when added to the growth medium¹⁻³. For example, when a yeast which did not ferment sucrose was grown in wort containing a preparation of deoxyribonucleic acid derived from a sucrose-fermenting strain, the transfer of part of the culture to a bijou bottle containing sucrose dissolved in yeast water (3 per cent Difco yeast extract in water) resulted in fermentation. Single-cell isolates obtained from the treated yeast, which had been serially subcultured through the same medium, also fermented sucrose, and on crossing with the original acceptor strain gave Mendelian segregation of sucrose-fermenting power. These observations were explained¹⁻³ by assuming that nuclear transformations akin to that already observed in various bacterial species⁴⁻⁹ had been induced in the acceptor yeast by the deoxyribonucleic acid from the donor. In view of the potential importance of such transformation from both the technological and scientific points of view an attempt has been made to investigate this phenomenon further.

The yeast strains used were those originally employed by Oppenorth². The acceptor strains included (1) R7, a yeast which was originally isolated by Winge and Roberts as a descendant of crossings between strains of *Saccharomyces cerevisiae*, *Saccharomyces chevalieri* and *Saccharomyces italicus*, and (2) *S. chevalieri* K83S58. Both acceptor yeasts fermented galactose and glucose but neither fermented raffinose or sucrose. The donor strain was *S. chevalieri* W332, which fermented both raffinose and sucrose.

Preparations of deoxyribonucleic acid were obtained from 48-hr. cultures of the donor yeast grown in shake culture at 25° C. in either wort or a medium consisting of yeast extract (Difco, 0.3 per cent), malt extract (0.3 per cent), peptone (0.5 per cent) and glucose (1.0 per cent) in water. The extraction procedure for deoxyribonucleic acid and the method of dissolving the product in wort were as described by Oppenorth². As will emerge, a critical finding was that the sterilization procedure used for the solution of deoxyribonucleic acid affected the result. The solution was sterilized either by (a) filtration through a glass filter (porosity S) or (b) filtration through a Seitz filter containing a Ford 'Sterimat' pad (grade SB). A solution (3.0 ml.) of ethanolic hydrogen chloride, prepared by diluting concentrated hydrochloric acid (8.0 ml.) to 100 ml. with ethanol, was added to aliquot portions (1.0 ml.) of the solution of deoxyribonucleic acid before and after sterilization. After standing for 15 min. the resulting precipitate was removed by centrifugation, washed with ethanolic hydrogen chloride and dissolved in water for estimation of deoxyribonucleic acid content by the method of Seibert¹⁰. It was afterwards found that sterilization by method (a) had no significant effect on the concentration of deoxyribonucleic acid, but sterilization by method (b) completely removed the deoxyribonucleic acid from solution in wort.

The effects of the solutions obtained by methods (a) and (b) on the acceptor strains were then investigated. In a typical case a series of McCartney bottles containing wort (4.0 ml.) or the test solution (4.0 ml.)

* No growth was observed on sucrose plates or sucrose-gelatin slides

was inoculated from a 1-day culture of yeast R7 grown in wort. The yeast was incubated with shaking at 25° C. for 4 days. After growth the wort was removed by centrifugation and the residual yeast suspended in water (0.2 ml.). Aliquot portions (0.04 ml.) of the suspensions were then transferred in duplicate to bijou bottles, individually containing sucrose (2 per cent) dissolved in yeast water, while the remaining yeast was washed four times with water. The latter yeast was suspended finally in water (0.12 ml.) and duplicate portions (0.04 ml.) were transferred to sucrose medium as before. At the same time a portion of the washed yeast suspension was serially diluted with water to give cell concentrations of approximately 1×10^8 , 5×10^5 and 1×10^3 cells/ml. and portions (0.02 ml.) of these suspensions were inoculated on to a solid medium prepared by the incorporation of agar (Davis 'Nutrient', 2 per cent) into the synthetic medium of Harris and Thompson¹¹ and using sucrose (0.5 per cent) as the source of carbon instead of glucose. The donor yeast grew satisfactorily on this medium while the acceptor yeasts failed to grow although they were viable as shown by growth when glucose was the carbon source. The bottles and plates were incubated at 25° C. and examined at intervals over a period of 30 days. The ability of the yeast to grow on the synthetic medium containing sucrose as sole carbon source was also investigated by means of the haemocytometer slide-culture technique of Gilliland¹², which more accurately reflects the ability of cells to grow than the conventional plating techniques. In this instance, a portion of the washed yeast was suspended in the synthetic medium containing gelatin (6 per cent) and incubated on the slide at 18° C. for 6 hr. The slides were then examined microscopically for microcolonies arising from sucrose-fermenting strains. The results (Table 1) show that: (1) the ability of the acceptor yeast to ferment sucrose was lost by thorough washing; (2) the presence of deoxyribonucleic acid in the growth medium was not necessary for a positive fermentation result to be observed; and (3) the ability of the yeast to ferment sucrose was not reflected in its ability to grow on solid medium with sucrose as sole carbon source.

A possible explanation of the results was that invertase was present in the deoxyribonucleic acid preparations used. To investigate this possibility, portions (0.01 ml.) of the deoxyribonucleic acid/wort solution were added to bijou bottles containing sucrose or raffinose (2.0 per cent) dissolved in yeast water. After incubating for 24 hr. at 25° C. the sugars present were examined by chromatography using a mixture of ethyl acetate, pyridine and water (10:4:3, v/v) as developing solvent and the dip

reagent of Harris and MacWilliam¹³ for detecting the sugars. It was thus found that considerable hydrolysis of sucrose and raffinose to monosaccharides had in fact occurred. Clearly, the deoxyribonucleic acid preparation was contaminated with invertase in sufficient quantity to yield monosaccharides responsible for the positive fermentation tests observed in the earlier work. Moreover, the enzyme passed through the Seitz filters used and gave rise to the positive fermentation tests even in the absence of deoxyribonucleic acid. It is therefore apparent that such fermentation tests are insufficient in themselves to indicate transformation. The further evidence for transformation presented earlier, namely, the isolation of single cells capable of fermenting sucrose or raffinose from subcultures originally not possessing this faculty, is not conclusive. In this connexion, the presence of hydrolytic enzymes in the test medium will allow growth to occur on the monosaccharides produced when the yeast is sub-cultured through a series of bijou bottles containing the test polysaccharide. In these circumstances cells capable of fermenting the polysaccharide might arise by mutation and subsequent selection even though controls not containing the deoxyribonucleic acid-enzyme mixture as used by Oppenoorth² fail to produce mutants of this type. It appears therefore that the evidence presented for transformation of yeasts in the manner suggested is capable of alternative explanation, and that further investigation is required to substantiate the earlier claims.

VIROLOGY

Plaque Formation by an Orphan Virus of Fowls

WHEN Sharpless *et al.*¹ and Fontes *et al.*² reported the adaptation of fowl lymphomatosis virus (RPL.12) to chicken embryo tissue culture, and later when plaque assay methods were described for this virus³⁻⁵, there was promise of an *in vitro* system for the study of viral oncogenesis. However, the suspicion that this virus may not in fact be the causal agent of fowl lymphomatosis was aroused when it was found that the inoculation of high-titre tissue culture material into chickens of a stock known to be susceptible to the ES4 strain of fowl lymphomatosis virus was not followed by the formation of tumours even after six months. Moreover, when these birds were challenged with ES4 virus, they were found to be completely

Fig. 1

susceptible (Carr, J. G., Macpherson, I. A., and Stoker, M. G. P., unpublished results). It was also shown that a high dilution of pooled normal sera from the ES4 susceptible flock neutralized plaque formation by the virus in tissue culture. A possible explanation of these results is that the virus we were studying was a fowl orphan virus present in poultry stocks. Since then confirmation has been received in personal communications from B. R. Burmester, G. R. Sharpless and R. J. Huebner, respectively, giving results of extensive investigations in the United States. These show that the virus is enzootic in many flocks.

Despite its apparent lack of relationship to fowl lymphomatosis this ubiquitous and hardy virus may be of considerable interest in its own right. The purpose of this communication is to describe an improved method of plaque assay which is more sensitive and gives considerably better resolution than the techniques previously reported. It has the additional advantage that it can be adapted for rough assays of both virus and neutralizing antibody.

The method was based on that described by Cooper⁶. Base layers of 4 ml. containing 10 per cent calf serum, 10 per cent tryptose phosphate broth (Difco) and 0.9 per cent agar (Difco) in Eagle's medium were prepared in 60-mm. Petri dishes. When the base layers had set they were overlaid with 2.5 ml. of the same medium containing 0.1 ml. of virus dilution and 3×10^7 freshly trypsinized liver cells from 17-day-old chick embryos. On the fourth day of incubation 2.5 ml. of 0.01 per cent neutral red in agar medium was added and plaques (Fig. 1) counted daily until a maximum count was obtained 3-4 days later.

Table 1. RELATIVE SENSITIVITIES OF PLAQUE TECHNIQUES FOR FOWL ORPHAN VIRUS

Method	Relative sensitivity
Agar suspension technique as described in the text with:	
(1) Chick embryo liver	100
(2) Chick embryo kidney	100
(3) Whole chick embryo	4
(4) Young adult fowl liver	65
Monolayers of chick embryo liver (ref. 4)	13

The relative sensitivity of this method compared with other systems is given in Table 1. Although chick embryo kidney cells were found to be as sensitive as liver cells, the latter were preferred since higher yields could be obtained. For rough assays 0.1 ml. of virus dilution or virus/antibody mixture was added to 0.9 ml. of agar medium held at 44° C. and 0.02 ml. of this agar dilution was allowed to set on a base layer. A 60-mm. Petri dish accommodates 6-8 spots. When set, the spots were overlaid with liver cells in agar and then treated as described above. Since discrete plaques can be distinguished in these spots a direct measure of infectivity is obtained.

It will be seen from Fig. 1 that there was a continuous gradation of plaque size (0.5 mm.-5 mm. diameter). When cloned virus from large and small plaques was plated, the same wide distribution of plaque size was obtained from each clone. Incubation of virus and cells in fluid suspension for 2 hr. before plating did not lead to greater uniformity of plaque size. Buthala also found several sizes of plaques when this virus was plated on monolayers of chicken embryo kidney. The explanation of this effect is not known.

B. R. Burmester, G. R. Sharpless and A. K. Fontes⁷ have found that this virus is in some ways similar to the adenoviruses of man and have suggested that it be called *GAL* (gallus, adenolike).

I wish to express my thanks to Prof. M. G. P. Stoker for his helpful advice and criticism.

Effect of Ultrasonic Vibration on the Hæmagglutinating Activity of Some Para-influenza Viruses

THE effect of sound vibration on influenza virus has been described previously^{1,2}. Lief and Henle³ showed that sonic treatment of influenza virus neither increased the hæmagglutinin titre nor changed the ratio of the hæmagglutinin titres obtained with chicken and guinea pig erythrocytes. The results briefly reported here deal with the effect of ultrasonic vibration on the hæmagglutinating activity of some para-influenza viruses.

Different para-influenza viruses were cultivated in cultures of calf or monkey kidney cells. Culture fluids containing large amounts of infectious virus were centrifuged at 2,500 r.p.m. for 30 min. The supernatants were subjected to ultrasonic vibration at about 20 kc./sec. for 10 min. in an MSE Mullard ultrasonic disintegrator. The hæmagglutinin tests were generally performed at 4° C. employing guinea pig and chicken erythrocytes.

Table 1. GUINEA PIG HÆMAGGLUTININ TITRES OF UNTREATED AND ULTRASONIC-TREATED VIRUSES

	Incuba- tion	Para- influenza-1 Sendai	Para- influenza-2 CA	Para- influenza-3 Umeå*	SA S1†
Untreated	4° C.	8	2	16	16
Treated	4° C.	128	16	128	256
Untreated	37° C.	128	8	128	64
Treated	37° C.	256	16	256	256

* A Swedish bovine strain.

† A Swedish strain of the myxovirus SA, described by Schultz and Habel (ref. 4).

The results presented in Table 1 show that if the hæmagglutinin tests were performed at 4° C., the guinea pig hæmagglutinin titres increased 8-16 times after ultrasonic treatment of virus. If, however, the hæmagglutinin tests were performed at 37° C., the guinea pig hæmagglutinin titres were higher and did not increase to the same extent after treatment.

The rise in guinea pig hæmagglutinin after ultrasonic treatment was not accompanied by an increase of chicken hæmagglutinin (Table 2). Similar observations have been made with influenza virus treated with ether⁴. To ascertain whether the effect of ultrasonic vibration was due to a release of non-infectious and less-sedimentable hæmagglutinin, untreated and treated virus samples were centrifuged at 25,000 r.p.m. for 1 hr. in a Spinco preparative centrifuge. The supernatants and sediments were titrated for hæmagglutinin and infectivity. The results of this experiment are recorded in Table 3, which shows that the level of hæmagglutinin was 16 times greater in the supernatant of the treated virus than in that of the untreated virus. Furthermore, the ratio guinea pig hæmagglutinin/*TCD*₅₀ was about 100 times greater in the supernatant than in the sediment of ultrasonic-treated virus.

Table 2. HÆMAGGLUTINATING ACTIVITY OF UNTREATED AND ULTRASONIC-TREATED VIRUS

Virus	Untreated		Treated	
	GPHA	CHA	GPHA	CHA
Sendai	8	128	128	128
CA	2	2	16	2
Umeå	16	<2	128	<2
S1	16	128	256	186

GPHA, Guinea pig hæmagglutinin; CHA, chicken hæmagglutinin.

Table 3. GUINEA PIG HÆMAGGLUTININ TITRES OF PARA-INFLUENZA VIRUS CENTRIFUGED AT 25,000 R.P.M. FOR 1 HR.

Titre/ml.	Untreated		Ultrasonic treated	
	Supernatant	Sediment	Supernatant	Sediment
GPHA	8 (8)*	32 (256)	128 (128)	256 (256)
log <i>TCD</i> ₅₀	5.9	7.9	5.7	8.1

* After ultrasonic treatment.

The effect of ultrasonic vibration on the hæmagglutinating activity of para-influenza viruses may be due to a disaggregation of a non-infectious hæmagglutinin. Further investigations dealing with this hypothesis will be published later.

FORTHCOMING EVENTS

Monday, January 2

PLASTICS INSTITUTE (in the Lecture Theatre of the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Mr. H. A. Thomas: "Plastics and Textiles" (Young People's Lecture).

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. H. F. Corsan: "Financial Management in the Chemical Industry".

Wednesday, January 4

BRITISH OCCUPATIONAL HYGIENE SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 10 a.m.—Meeting on "Health Physics".

SOCIETY OF CHEMICAL INDUSTRY, CORROSION GROUP—CATHODIC PROTECTION PANEL (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Discussion of "Galvanic Anodes". Opening Speakers: Dr. G. E. Gardam, Mr. P. V. Palmer and Mr. K. P. Scott.

BRITISH INSTITUTION OF RADIO ENGINEERS, RADAR GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. W. E. Brunt: "Automatic Techniques in Civil Air Line Communications Systems".

Thursday, January 5

INSTITUTION OF MECHANICAL ENGINEERS, INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP (at 1 Bridgegate Walk, Westminster, London, S.W.1), at 10.30 a.m.—Informal Discussion on "The Reliability of Mechanical Engineering Parts of Data Processing Systems".

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 3 p.m.—Mr. R. J. Lees: "Gyroscope and Pendulum—the Modern Travel Agents" (Young People's Lecture).

ROYAL INSTITUTION OF NAVAL ARCHITECTS (at 10 Upper Belgrave Square, London, S.W.1), at 4.45 p.m.—Mr. A. Hunter, O.B.E.: Third Amos Ayre Lecture.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 6.30 p.m.—Dr. J. S. Forrest: "The Application of Electronics to the Electricity Supply Industry" (Third Hunter Memorial Lecture).

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 17 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. J. E. Hughes: "Metallurgy in Electronics".

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, MEDICAL GROUP (at 16 Princes Gate, London, S.W.7), at 7 p.m.—Mr. Charles Engel and Mr. John Brace: "Closed Circuit Television in Medical Diagnosis, Research and Teaching".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER IN PSYCHOLOGY IN THE DEPARTMENT OF PHILOSOPHY—The Registrar, University College, Singleton Park, Swansea (January 14).

LECTURER IN PHYSICS (EXPERIMENTAL); a LECTURER IN THEORETICAL PHYSICS; and ASSISTANT LECTURERS IN PHYSICS—The Registrar, The University, Manchester 13 (January 14).

RESEARCH ASSISTANT (with some knowledge of metallurgical techniques) for work in the metal physics group under the direction of Dr. P. B. Hirsch—The Secretary to the Department of Physics, Cavendish Laboratory, The University, Free School Lane, Cambridge (January 15).

LECTURERS IN VETERINARY HISTOLOGY AND EMBRYOLOGY—The Secretary of University Court, The University, Glasgow (January 18).

CHAIR OF MECHANICS—The Registry, The Old Schools, The University, Cambridge (January 21).

SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with a good honours degree, preferably with postgraduate experience), to work on biochemical processes in seeds and seedlings—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (January 21).

LECTURER or ASSISTANT LECTURER IN STATISTICS—The Registrar, The University, Leeds 2 (January 24).

SENIOR LECTURER or LECTURER IN MATHEMATICS IN THE FACULTY OF ENGINEERING, University College of the West Indies, Trinidad—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 26).

LECTURER IN THE DEPARTMENT OF FOOD TECHNOLOGY at the University of New South Wales—The Agent-General for New South Wales, 56 Strand, London, W.C.2, and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, marking envelope "University Appointment" (Australia and London, January 27).

LECTURERS or ASSISTANT LECTURERS IN SOCIAL ANTHROPOLOGY, GEOLOGY, MATHEMATICS and PHYSICS at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (January 30).

SENIOR LECTURER (preferably with research interest in the application of mathematics to some engineering subject) IN ENGINEERING MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (January 30).

CHAIR OF PHARMACOLOGY in The University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa and London, January 31).

PLANT BREEDERS (2) (with a degree in agriculture or science or an equivalent) within the University of Sydney, to carry out wheat breeding at the North-West Wheat Research Institute, Narrabri—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia and London, January 31).

SENIOR LECTURER IN ANIMAL PRODUCTION (MORTLOCK FELLOW) IN THE DEPARTMENT OF AGRONOMY at the Waite Agricultural Research Institute, University of Adelaide, Adelaide, South Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, January 31).

UNIVERSITY LECTURER (with special qualifications in applied thermodynamics, and preferably an interest in heat transfer apparatus and some industrial or research experience) IN MECHANICAL ENGINEERING—The Secretary, The University, Aberdeen (January 31).

LECTURER IN HYDRAULICS AND HYDROLOGY IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, King's College (University of Durham), Newcastle upon Tyne 1 (February 4).

AGRONOMIST or PLANT PHYSIOLOGIST (honours graduate in science or agricultural science with relevant postgraduate research experience, and preferably prior experience with tobacco) at the Tobacco Research Institute, C.S.I.R.O., Maresba, North Queensland, to investigate factors affecting the nitrogen status of the tobacco plant, together with various problems in tobacco agronomy arising in North Queensland—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 815/29 (February 11).

CHAIR OF GEOLOGY tenable in the Newcastle Division of the University of Durham—The Registrar, University Office, 46 North Bailey, Durham (February 11).

LECTURER (with special qualifications or experience in inorganic or physical chemistry) IN CHEMISTRY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand and London, February 17).

CHAIR OF APPLIED MECHANICS tenable in the Newcastle Division of the University of Durham—The Registrar, University Office, 46 North Bailey, Durham (February 18).

ASSISTANT EXPERIMENTAL OFFICER (with a degree in science or diploma in horticulture or agriculture), to assist in field experimental work—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick.

ASSISTANT LECTURER (graduate in chemistry, and preferably with experience in the food industry), for duties which will include the teaching of chemistry and food quality control—The Principal, National College of Food Technology, St. George's Avenue, Weybridge, Surrey.

BIOCHEMIST (graduate in chemistry, biochemistry or physiology) IN THE PATHOLOGY DEPARTMENT, for work connected with biochemical investigations on patients—The Group Secretary, or Consultant Pathologist, Camberwell Hospitals Management Committee, Dulwich Hospital, East Dulwich Grove, London, S.E.22.

LECTURER IN CHEMICAL ENGINEERING—Head, Department of Chemistry and Chemical Engineering, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.

RESEARCH ASSISTANT (preferably with an honours degree in physical and inorganic chemistry) IN THE DEPARTMENT OF MINERALOGY AND PETROLOGY, for a programme of research concerning fundamental solid-state problems in the field of cement chemistry—Dr. J. D. C. McConnell, Department of Mineralogy and Petrology, Downing Place, Cambridge.

SENIOR LECTURER IN INORGANIC CHEMISTRY; a LECTURER IN INORGANIC CHEMISTRY; and a LECTURER IN CHEMICAL ENGINEERING—The Registrar, Bradford Institute of Technology, Bradford 7.

SENIOR TECHNICIAN or TECHNICIAN (with instrument or physics workshop experience) IN THE RADIOGRAPHY DEPARTMENT, for duties which include Physics Workshop, Isotope Laboratory, Radium and Mould Room work—The Group Secretary, Romford H.M.C., Oldchurch Hospital, Oldchurch Road, Romford, Essex, quoting Ref. 17/39.

GRIFFIN Oscillating Hotplate FISHER PATTERN

For simultaneous heating and agitating in many analytical techniques

Hotplate $18 \times 13\frac{1}{2}$ in. will accommodate up to twenty-eight
250 ml. or eighteen 400 ml. Griffin Beakers

Continuously variable temperature control. Loading 2 kw
216 circular oscillations per minute, $\frac{1}{8}$ in. diameter

Designed to save labour and time

- Metallurgical analysis** – maintains intimate contact between sample chips and acid
- Agricultural analysis** – for the rapid determination of potash in fertilisers
- Cement analysis** – faster dissolving of sample
- Petroleum analysis** – faster determination of saponification number

Many other uses include the determination of alkaloids, acid values of fats and fatty oils and in preparation for creatinine determinations.

APPOINTMENTS VACANT

UNIVERSITY OF WALES UNIVERSITY COLLEGE OF SWANSEA DEPARTMENT OF ENGINEERING

Owing to the large expansion of the Department facilities for both teaching and research, a number of appointments will be made to the Staff both immediately and from October 1, 1961. Applications are invited from graduates in Engineering, Physics, Metallurgy or Applied Mathematics for the following posts:

CIVIL ENGINEERING

Professor B. G. Neal

Lecturer or Assistant Lecturer with interests in any branch of Civil Engineering

CIVIL OR MECHANICAL ENGINEERING

Lecturer or Assistant Lecturer with special interests in Strength of Materials and related fields.

MECHANICAL ENGINEERING

Professor R. H. Macmillan

Two Lecturers or Assistant Lecturers, one with particular interests in the fields of Heat Transfer and Thermodynamics, the other preferably having experience in the Design of Machines, but applicants with other interests will be considered.

Research Demonstrator to undertake a limited amount of teaching and pursue supervised research preferably in Heat Transfer, Hydrodynamic power transmission, Fatigue or creep.

ELECTRICAL ENGINEERING

Professor W. Fishwick

Lecturer or Assistant Lecturer with special interests in Control Engineering, Electrical Apparatus or related fields.

Lecturer or Assistant Lecturer with interests in any branch of Electrical Engineering, including Theoretical Electro-technics.

Qualifications for, and further details of, these posts are as follows: Lecturer. Applicants should hold a good honours degree and have not less than three years postgraduate experience in research or industrial design. Excellent facilities exist for research. Assistant Lecturer. Applicants should hold a good honours degree and have at least one year's industrial or postgraduate experience. Research is strongly encouraged and the assistant may register for a Ph.D. degree. Research Demonstrator. Applicants should have obtained a good honours degree and have had at least one year's industrial or postgraduate experience. The appointment will be tenable for three years, during which time the holder will be expected to work for the Ph.D. degree, submitting a thesis at the end of the period.

Salaries are on the following scales, to which are added F.S.S.U. benefits and family allowances: Lecturer, £1,050 by £50 to £1,400 by £75 to £1,850 per annum; Assistant Lecturer, £800 by £50 to £950 per annum; Research Demonstrator, £700 per annum.

Further particulars can be obtained from the Registrar, University College, Singleton Park, Swansea, by whom applications (two copies), must be received not later than Saturday, January 21, 1961.

UNIVERSITY COLLEGE OF RHODESIA AND NYASALAND

Applications are invited for Lectureships or Assistant Lectureships in: GEOLOGY, MATHEMATICS, PHYSICS. Salary scales: Assistant Lecturer, £1,200 by £50 to £1,350 per annum; Lecturer, Grade II, £1,350 by £50 to £1,600 per annum; Grade I, £1,600 by £50 to £1,900 per annum. Passages to Salisbury for appointee, wife, and dependent children on appointment, with allowance for transport of effects. Superannuation and medical aid schemes. Unfurnished accommodation at rent of 15 per cent of salary. Assistance given for triennial visits overseas.

Detailed applications (six copies), naming three referees, by January 30, 1961, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

PLANT MANAGER DESIGNATE

A vacancy exists for an Assistant Plant Manager for an overseas processing unit. It would be intended that the successful applicant would work under the present Manager for a short period before succeeding him. The appointment calls for a qualified mechanical or chemical engineer with experience of the independent management of extraction or refining plant. A knowledge of solvent processes would be an advantage but not essential. Applicants should be not more than 45, preferably with overseas experience and probably earning at least £3,000 per annum at present.

Write, Box DE/41, c/o 95 Bishopsgate, E.C.2.

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES VACANCIES FOR STAFF IN SCHOOL OF BIOLOGICAL SCIENCES

The School of Biological Sciences of the University of New South Wales is under the leadership of the professor of Biochemistry (Professor B. J. Ralph) and consists of four departments. These are the Department of Biochemistry (Professor B. J. Ralph), Department of Microbiology (Professor to be appointed), Department of Botany (Dr. Mary Hindmarsh) and Department of Zoology (Dr. Elsie M. Stephenson). The undergraduate work of the School is concerned with the preparation of students at pass and honours levels. In biochemistry, microbiology, botany, zoology and entomology in the Faculty of Science, and biochemistry, microbiology and entomology in the Applied Biology course. In 1962 and later years the relevant Departments will be responsible for medical biochemistry and medical microbiology in the courses in medicine and medical science. Specialized subjects are also provided for courses in the Faculty of Applied Science. All departments of the School are active in research and prepare students for Masters' degrees and for the Doctorate of Philosophy.

Lecturers in the Departments of Botany and Zoology are expected to assist generally with elementary teaching, but are otherwise encouraged to specialize within their own particular discipline. The Departments of Biochemistry and Microbiology are particularly concerned with the application of these sciences, and formal postgraduate courses in industrial biochemistry and microbiology are being developed. As the School handles a considerable number of part-time and full-time students, some evening lecturing is inevitable, but this is limited in extent. Applicants with experience and/or research interests in any of the divisions of botany or zoology, or in medical biochemistry or medical microbiology are particularly sought.

The following vacancies exist: Senior Lecturers, Lecturers All Departments. Teaching Fellows: Botany, zoology and biochemistry. Senior Tutors: Biochemistry, botany and microbiology. Tutor/Demonstrators: Botany and zoology.

Applicants should possess at least the following academic qualifications. Senior Lecturer, a higher degree or equivalent qualifications. Lecturer, a degree with honours or equivalent qualifications. For these positions postgraduate experience is desirable. Teaching Fellow: Applicants must possess a degree with honours. Teaching Fellows are required to register for a higher degree. Senior Tutor: a degree with teaching experience. Tutor: a degree. Tutors and Senior Tutors will have opportunity to study for a Master's degree on a part-time basis.

Further details may be obtained from the Head of the School of Biological Sciences.

Subject to satisfactory medical examination Lecturers and Senior Lecturers will be eligible to join the superannuation scheme. Teaching fellows and tutors, and normally senior tutors are subject to annual re-appointment (limit for teaching fellows normally three years' service).

Salary ranges: Senior Lecturer, £A 2,579 to £A 3,029 per annum. Lecturer, £A 1,759 to £A 2,464 per annum. Senior Tutor, £A 1,759 to £A 2,074 per annum. Teaching Fellow and Tutor, £A 1,129 to £A 1,349 per annum.

Passages to Sydney for appointees and their families. Commencing salary according to qualifications and experience.

Four copies of applications, including the names of two referees, should be lodged with the Agent-General for New South Wales, 56 Strand, London W.C.2, England, and a copy forwarded to the Appointments Section, the University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, by airmail to arrive before February 10, 1961. Applicants resident outside the United Kingdom and Eire need only submit one copy of their application to the London address.

UNIVERSITY OF MANCHESTER IMPERIAL CHEMICAL INDUSTRIES FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Imperial Chemical Industries Ltd., tenable in the University and available for research in various branches of Chemistry, Chemical Engineering, Engineering, Technology, Physics and allied subjects. The value of the Fellowships will be within the range of £800 to £1,100 per annum according to qualifications and experience.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester 13, to whom applications should be sent not later than February 14, 1961.

SENIOR RESEARCH OFFICER ELECTROLYTIC ZINC COMPANY OF AUSTRALASIA LIMITED

Applications are invited for a position as a Senior Research Officer in the Company's Research Department at Rusdon, near Hobart, Tasmania. Applicants should possess a university degree in chemistry or chemical engineering; they should have obtained honours or higher degrees, and should have had some years' experience in research. The Research Department is concerned with development projects and is responsible for the solution of problems which arise in connection with the Company's various activities, which include the production of zinc, ammonium sulphate, superphosphate, sulphuric acid, etc. The duties are essentially similar to those in the Research Department of any large chemical industry. Applicants should preferably be in the age range 28 to 35 years. The commencing salary offered for the position will depend on the qualifications and experience of the successful applicant, but will be at the rate of not less than £A2,100 per annum. In addition, a bonus based on the rate of dividends declared by the Company is paid half-yearly; for 1959 the bonus was approximately 15 per cent of salary. The appointee will be eligible to participate in the Company's Staff Provident Fund and in the Medical, Hospital and Dental Schemes run by the Company. The Company will pay fares for a successful applicant and his family (if any) to travel to Australia by sea. An unfurnished house or flat can be made available on a rental basis for a married applicant.

Applications should include details of education and experience and must include details of subjects studied at the University and the standard of passes obtained. Applicants should include the names of at least three referees and should be addressed to: The General Superintendent, Electrolytic Zinc Company of Australasia Limited, G.P.O. Box 377-D, Hobart, Tasmania, Australia.

COMMONWEALTH MYCOLOGICAL INSTITUTE

Applications are invited for the post of Abstracter. Candidates should have sound knowledge of German and Dutch and ability to abstract in English from these languages. Scandinavian and/or Spanish and Portuguese languages an added qualification. Knowledge of microbiology and/or botany an advantage. Salary according to qualifications and experience in the range £640 to £1,325 per annum.

Apply in writing, the Director, Ferry Lane, Kew.

DSIR ROAD RESEARCH LABORATORY,

Harmondsworth, Middlesex, requires Scientific Officers or Senior Scientific Officers for research: (1) Physicists on rheology of solid-liquid systems and of viscous and visco-elastic fluids to provide basic information for design of bituminous and concrete road mixtures. (Ref. A.521/OA); (2) Chemists on problems of surface chemistry and other physico-chemical aspects of behaviour of bituminous road materials also on problems arising from presence of organic matter in soils. (Ref. F.857/OA); (3) Civil and Mechanical Engineers on (a) mechanical mixing and laying of bituminous road surfacing materials, (b) problems of design and construction of earthworks for roads (practical experience of site work an advantage), (c) stabilised soil and cement-bound base materials. (Ref. B.473/OA). Varied and interesting work both in laboratory and field, providing contacts with other scientists and engineers in U.K. and abroad. Facilities for qualifying for A.M.I.C.E. for posts (3) above. Qualifications, first- or second-class honours degree or equivalent for Scientific Officers. For Senior Scientific Officers at least three years' postgraduate experience. Salary (men) Scientific Officer, £730 to £1,205. Senior Scientific Officer, £1,330 to £1,640. Prospects of promotion in mid-thirties to Principal Scientific Officer, £1,700 to £2,375.—Forms from Ministry of Labour, Technical and Scientific Register (K), 26 King Street, London, S.W.1 (quote appropriate reference). Closing date January 31, 1961.

ROYAL VETERINARY COLLEGE (University of London). Research Assistant required in the Department of Animal Husbandry and Veterinary Hygiene for studies in poultry husbandry. The appointment will be for two years in the first instance under a grant from the Agricultural Research Council. Candidates must possess a suitable veterinary qualification or a degree in agriculture or natural science. Salary according to age, qualifications and experience. Superannuation under F.S.S.U.—Application forms and further particulars, obtainable from the Secretary, Royal Veterinary College, Royal College Street, London, N.W.1, should be returned not later than January 14, 1961.

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES
PROFESSOR OF GEOLOGY

The University invites applications for appointment to the position of Professor of Geology in the School of Mining Engineering and Applied Geology. Salary will be £A 4,279 per annum. The School is a composite one and includes departments of Mining Engineering, Geology and Geophysics, Fuel Technology and Mineral Beneficiation. The Department of Geology conducts courses leading to the degree of Bachelor of Science in Applied Geology and also in pure Geology. The main emphasis in the School is on applied geological research and it is essential that applicants should have high academic qualifications in geology with substantial interest, experience and research record in some aspects of applied geology. The Head of the School is Professor D. W. Phillips who is also the Pro-Vice-Chancellor. The Professor appointed will be expected to assist him with the administration of the School to that some familiarity with the disciplines of the other departments in the School would be desirable. Applicants interested in this position may obtain further details relating to the staff and activities of the School from the Dean of the Faculty of Technology, Professor Myers. Subject to the consent of the Council of the University, Professors may engage in a limited amount of higher consultative work. The successful applicant will be eligible, subject to satisfactory medical examination, to join the superannuation scheme which provides a maximum pension of £A 2,184 per annum. First-class ship fares to Sydney of appointee and his family will be paid. Professors are eligible for six months' study leave on full salary after three years of service, or twelve months after six years of service. The University reserves the right to fill the Chair by invitation. With the approval of the University and its bankers, married men may be assisted by loans to purchase a home.

Four copies of application (including the names of three referees and a recent photograph of the applicant) should be lodged with the Agent-General for New South Wales, 56-57 Strand, London, W.C.2, England, and a copy forwarded to the Appointments Section, the University of New South Wales, P.O. Box 1, Kensington, N.S.W., Australia, to reach there before February 3, 1961. Applicants outside the United Kingdom need only submit one copy of their application to the London address.

GOVERNMENT OF THE
FEDERATION OF RHODESIA
AND NYASALANDVACANCY: ENTOMOLOGIST
DEPARTMENT OF TSETSE AND
TRYPANOSOMIASIS CONTROL AND
RECLAMATION

MINISTRY OF AGRICULTURE

Applications are invited for the post of Entomologist in the Tsetse and Trypanosomiasis Control and Reclamation Branch of the Ministry of Agriculture, based in the tsetse areas of Southern Rhodesia. Duties will be mainly on field investigations, preparatory to tsetse control projects, and in their direction. Applicants must have a university degree, preferably honours in a biological subject, zoology, entomology (need not have specialized, but previous relevant experience is an advantage), botany. Commencing salary will be between £735 per annum and £1,365 per annum, depending on qualifications and relevant post-qualification experience, in a scale rising to £1,732 10s. per annum. A field allowance of £7 10s. per month is payable at present for officers living under field conditions. Passages are provided for recruits and their families to the Federation, and conditions include security, good pensions, generous sick leave, vacation and occasional leave, medical aid, grants towards holiday travel, low income tax.

Application forms and further details from Secretary (R), Rhodesia House, 429 Strand, W.C.2. Closing date January 7, 1961.

UNIVERSITY OF MANCHESTER
TURNER AND NEWALL RESEARCH
FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Messrs. Turner and Newall Ltd., tenable in the University and available for research in engineering, inorganic chemistry, physics and allied subjects. The value of the Fellowships will be within the range of £800 to £1,100 per annum according to qualifications and experience.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester 13, to whom applications should be sent not later than February 14, 1961.

WELSH COLLEGE OF ADVANCED
TECHNOLOGY

CATHAYS PARK, CARDIFF

DEPARTMENT OF APPLIED PHYSICS

Applications are invited for the posts of (a) Lecturer or Assistant Lecturer (Grade B) in Electronics, (b) Assistant Lecturer (Grade B) in Physics. Applicants should have a good honours degree in physics or electrical engineering, and be able to teach (a) Electronics and/or Telecommunications, (b) Physics and/or Applied Physics, to students taking Dip Tech. Courses, and have had industrial and/or research experience. Teaching experience at University or Technical College level would be an advantage. Successful candidates would be expected to pursue some research and every assistance and encouragement will be given to this end. The Department's research activities are largely confined to Solid State Physics and application from those particularly interested in some aspect of Solid State Physics or Applied Physics would be particularly welcome. Salary (a) Lecturer, £1,370 by £35 to £1,550 per annum (b) Assistant Lecturer (Grade B), with good honours degree, £865 by £27 10s. to £1,315 per annum starting salary according to qualifications. Further particulars and application forms can be obtained from the Registrar at the College, to whom they should be returned by January 14, 1961.

ROBERT E. PRESSWOOD,
Clerk to the Governing Body.

City Hall,
Cardiff.

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES
SENIOR LECTURER IN PHYSIOLOGY
FACULTY OF MEDICINE

The University invites applications for appointment to the position of Lecturer in the School of Physiology within the Faculty of Medicine. Salary £A 2,579 range £A 3,029 per annum. Commencing salary according to qualifications and experience. Applicants must have research and teaching experience in the fields of cardiovascular physiology and respiratory physiology. The successful applicant will participate in the new teaching programme of the School and establishment of the cardiopulmonary research laboratory. The appointee will be expected to enter on duty in this position about June, 1961. First-class ship fares to Sydney of the appointee and his family will be paid. Appointee will be eligible, subject to satisfactory medical report, to contribute to the State Superannuation Fund.

Four copies of applications (including the names of two referees) should be lodged with the Agent-General for New South Wales, 56 Strand, London, W.C.2, and a copy forwarded by airmail in an envelope marked "University Appointment" to the Bursar, the University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, before January 31, 1961. Applicants resident outside the United Kingdom and Eire need only submit one copy of their application to the London address.

AGRICULTURAL RESEARCH
COUNCIL

Assistant Experimental Officer required, to be responsible for preparative work in a research programme concerned with biochemical and developmental genetics. General experience of biological laboratory methods and a special experience of biochemistry, genetics embryology or histology, an advantage. Salary within scale £490 to £945 according to age. Candidates should have a School Leaving Certificate with passes in three subjects at higher level, including two science subjects; a Higher National Certificate, or equivalent. Superannuation.

Apply, with names of three referees, to the Secretary, Poultry Research Centre, King's Buildings, West Mains Road, Edinburgh, 9, within two weeks.

ESSEX COLLEGE

ASSUMPTION UNIVERSITY OF WINDSOR
WINDSOR, ONTARIO, CANADA

The Department of Physics offers Graduate Assistantships to candidates wishing to proceed to an M.Sc. in physics. Stipend up to \$2,000 for eight months, depending on qualifications and duties in the department. There is a possibility of additional income during the summer months. At present research is proceeding in beta-ray spectroscopy, optical pumping, molecular collision problems, and electromagnetic interactions in shock waves.

Inquiries should be addressed to the Chairman, Department of Physics, Assumption University of Windsor.

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES
LECTURER IN FOOD TECHNOLOGY

The University invites applications for appointment to the position of Lecturer in the Department of Food Technology. Salary: £A 1,759 range £A 2,464 per annum. Commencing salary according to qualifications and experience. Applicants should possess a degree with honours in biochemistry or microbiology, or equivalent qualifications, and some previous experience in the food industry is desirable but not essential. The successful applicant will lecture to undergraduate and postgraduate students in food technology and undertake research in some aspects of biochemistry or microbiology, as applied to food science or food technology. First-class ship fares to Sydney of appointee and his family will be paid. Successful applicant will be eligible to contribute to the State Superannuation Fund.

Four copies of applications, including the names of two referees, should be lodged with the Agent-General for New South Wales, 56 Strand, London, W.C.2, and a copy forwarded by airmail in an envelope marked "University Appointment" to the Appointments Section, the University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, before January 27, 1961. Candidates outside the United Kingdom and Ireland need only submit one copy of their applications to the London address.

AUSTRALIA

UNIVERSITY OF NEW SOUTH WALES
FACULTY OF ENGINEERING
TEACHING FELLOWS

Vacancies for teaching fellows exist in the Schools of Mechanical, Electrical and Civil Engineering. Applicants must possess a degree with honours, and will be expected to enrol for a higher degree and undertake a limited amount of teaching duties. Engagement is on an annual basis to a maximum of three years. Salary: £A 1,129 range £A 1,349 per annum. Commencing salary for all positions will be according to qualifications and experience.

Further details regarding these positions may be obtained from the Head of the appropriate school. Ship fares to Sydney of appointees and their families will be paid. Four copies of applications (including the names of two referees), should be lodged with the Agent-General for New South Wales, 56-57 Strand, London, W.C.2, and a copy forwarded by airmail to the Appointments Section, the University of New South Wales, Box 1, Post Office, Kensington, New South Wales, Australia, before January 27, 1961.

UNIVERSITY OF ST. ANDREWS

Applications are invited for a Senior Lectureship or a Lectureship in Electrical Engineering in the Department of Electrical Engineering, Queen's College, Dundee, to commence not later than October 1, 1961. It is intended to appoint the most suitable candidate irrespective of his particular interest. Salary scales: Senior Lectureship, £1,925 by £75 to £2,425; Lectureship, £1,050 by £50 to £1,400 by £75 to £1,850 (efficiency bar £1,400). F.S.S.U.; family allowance, grant towards furniture removal expenses.

Applications (six copies), containing the names of three referees, to the undersigned, from whom further particulars may be obtained, not later than January 21, 1961.

PATRICK CUMMING,

Joint Clerk to the University Court
Queen's College,
Dundee.

UNIVERSITY COLLEGE OF THE
WEST INDIES

Applications are invited for (a) Senior Lectureship and (b) Lectureship in Geology. The Senior Lecturer will be for the time being, the Head of the Department of Geology which is about to be established and which will prepare students for degrees of University of London as from October, 1961. Salary scales (under review) (a) £1,500 by £75 to £2,250 per annum. (b) £1,150 by £50 to £1,450 by £75 to £1,900 per annum. Point of entry determined by qualifications and experience. Child allowance. F.S.S.U. Unfurnished accommodation at rental not in excess of 10 per cent of basic salary. Up to five full passages on appointment, termination and study leave (once every three years). Duties to be assumed by April 1, 1961, or as soon as possible thereafter. The Head of Department will be eligible for entertainment allowance at the rate of £200 per annum.

Detailed applications (six copies), naming three referees, by January 27, 1961, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

AUSTRALIA
COMMONWEALTH SCIENTIFIC AND
INDUSTRIAL RESEARCH ORGANIZATION

RESEARCH PHYSICIST

The Organization's Division of Metrology, National Standards Laboratory, Sydney, N.S.W., invites applications for the position of Research Physicist in the Interferometry Section from honours graduates, majoring in physics with some years' postgraduate research experience, preferably to Ph.D. level.

The Section, which has a well-equipped vacuum coating laboratory as well as equipment for studying surfaces and thin films by multiple-beam interferometry, is engaged on research and development in interferometry, particularly the measurement of length and associated quantities such as flatness, surface structure and optical phase change at reflection. The appointee is required for research in interference spectroscopy and light source development involving the production study and use of various spectral radiations from isotopic light sources as primary and secondary wavelength standards in metrology.

SALARY: Dependent on qualifications and experience within the ranges: £A 1,510 to £A 2,265 per annum or £A 2,395 to £A 2,720 per annum.

Promotion within C.S.I.R.O. is by merit and may ultimately go beyond the upper limit of the scale within which the original appointment is made.

Fares paid. Further information on conditions etc., supplied on application to.

Mr. E. J. Drake, Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2,

to whom applications (quoting Appointment No. 750/222) should be addressed by February 11, 1961.

UNIVERSITY OF EDINBURGH

Applications are invited for I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology, Physics or Chemical Technology (Chemical Engineering), normally tenable for a period of three years. Some appointments will date from October 1, 1961 (or earlier in the case of selected candidates who may be available before that date). The initial salary will depend upon qualifications and experience, but will normally be within the range £800 to £1,100 per annum, together with F.S.S.U. benefits and family allowance. In the case of an overseas applicant, the University is also prepared to consider the provision of an allowance towards defraying the cost of travel to and from Great Britain. Forms of application and further particulars may be obtained from the undersigned.

Applications (two copies), should be submitted not later than February 16, 1961.

CHARLES H. STEWART,
Secretary to the University.

UNIVERSITY OF MELBOURNE SENIOR LECTURESHIP IN CLINICAL BIOCHEMISTRY

Applications are invited for the above-mentioned position. The Senior Lecturer's duties will be chiefly with medical students and it is essential that he should be familiar with modern methods in clinical biochemistry. It is also desirable that he should hold a medical qualification. The salary range is £A 2,480 per annum to £A 2,950 per annum or, if medically qualified, £A 2,600 per annum to £A 3,250 per annum. Commending salary will be fixed according to qualifications. Superannuation similar to F.S.S.U. in Great Britain will be provided.

Conditions of appointment may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close in Australia and London on February 4, 1961.

UNIVERSITY OF OXFORD DEPARTMENT OF BIOCHEMISTRY

It is proposed to appoint a Departmental Demonstrator in Biochemistry as soon as possible. The salary will be up to £1,000 per annum (or up to £1,150 in the case of medically qualified candidates). The person appointed will be required to become a member of the Federated Superannuation System for Universities not later than two years after the date of his appointment, and an allowance of £50 per annum for each dependent child is payable.

Three copies of application, including a statement of own qualifications and experience and giving the names of two referees, should be sent to the Administrator, Department of Biochemistry, South Parks Road, Oxford, not later than March 4, 1961.

FEDERAL GOVERNMENT OF NIGERIA

SCIENTIFIC OFFICER

(MINERAL DRESSER)

The Geological Survey Division of the Federal Ministry of Mines and Power have vacancies for Scientific Officers (Mineral Dressers) to undertake research on mineral dressing, particularly in connection with the recovery of minerals from alluvial concentrates in the Plateau tinfields.

Candidates should hold a good honours degree in mineral dressing or mining engineering, preferably with some experience in industry. Candidates should preferably not be over 35 years of age.

Contract appointment for one tour of 15 to 18 months in the first instance with prospect of extension. Salary according to qualification and experience £1,434 to £2,196 per annum (including inducement addition) plus gratuity of £100 to £150 on satisfactory completion of service. Outfit allowance of £60 payable for salaries not exceeding £1,740. Free passages for officer and wife. Liberal home leave on full pay. Quarters and income tax at low local rates. Children's allowances while separated.

Write for application forms and further particulars, stating briefly age, qualifications and experience, to the Appointments Secretary, Federal Public Service Commission, Nigeria House, 9 Northumberland Avenue, London, W.C.2, quoting J.2/8.

IMPERIAL CANCER RESEARCH FUND

(DIVISION OF BIOCHEMISTRY)

Technical Officer (age 22 or over). Applicant should possess at least Higher National Certificate in Chemistry or equivalent qualifications, and have had experience in synthetic organic chemistry and/or micro-analysis and/or spectroscopy. Salary: £920 by £35 by £40 to £1,260 plus £20 London weighting. Junior Technical Officer (age 18 or over). Applicants should have G.C.E. A-level passes in chemistry and physics or equivalent. Training will be given in methods of micro-analysis and spectroscopy. Salary: £410 by £35 by £40 to £860 plus £10 London weighting.

Applications should be addressed to: Scientific Administrator, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2

UNIVERSITY OF LIVERPOOL

Applications are invited for Imperial Chemical Industries Research Fellowships in Physics, Chemistry, Biochemistry, Engineering, Metallurgy and Pharmacology or any related subjects. Appointments will date from October 1, 1961. The salary will depend upon qualifications and experience, but will normally be within the range £700 to £1,000 per annum, together with F.S.S.U. benefits and family allowances.

Applications, three copies, stating age, details of qualifications and experience, publications, and research work in progress and completed, together with the names of two referees, should be received not later than February 11, 1961, by the Registrar from whom further particulars may be obtained. (Candidates overseas who find it more convenient to do so may send one copy only by airmail. Ref. CV/N.)

FEDERAL GOVERNMENT OF NIGERIA

SCIENTIFIC OFFICER

(GEOPHYSICIST)

The Geological Survey Division of the Federal Ministry of Mines and Power have vacancies for Scientific Officers (Geophysicist) to conduct geophysical surveys using a.c. and d.c. resistivity apparatus, d.c. potential equipment, vertical forces magnetic variometer, shallow seismic gear, and equipment for logging resistivities and temperature gradients in boreholes.

Candidates must hold a good honours degree in geophysics, physics or engineering. Alternatively a good honours degree in geology, with physics or applied mathematics as subsidiary subjects. Experience in applied geophysics and some knowledge of electrical circuitry and an ability to maintain apparatus will be added advantages. Candidates should preferably not be over 35 years of age.

Contract: appointment for one tour of 15 to 18 months in the first instance with prospect of extension. Salary according to qualifications and experience £1,434 to £2,196 per annum (including inducement addition) plus gratuity of £100 to £150 on satisfactory completion of service. Outfit allowance of £60 payable for salaries not exceeding £1,740. Free passages for officer and wife. Liberal home leave on full pay. Quarters and income tax at low local rates. Children's allowances while separated.

Write for application forms and further particulars, stating briefly age, qualifications and experience, to the Appointments Secretary, Federal Public Service Commission, Nigeria House, 9 Northumberland Avenue, London, W.C.2, quoting J.3/8.

WEST AFRICAN COCOA RESEARCH INSTITUTE

GHANA

SENIOR BOTANIST

To take charge of the Botany Division comprising plant breeding and plant physiology sections. Candidates must have a first or second class honours degree in botany or equivalent qualification, with at least 15 years' research experience and a good record of published work. Proven ability to plan and supervise research programmes and experience with tree crops, preferably in the tropics, is also desirable. Appointment on contract/gratuity terms for two tours each of 15 to 18 months in the first instance. Salary in scale £2,460 to £2,940. Gratuity £12 10s. for each month of satisfactory service. Quarters with heavy furniture provided at moderate rental. Free return passages once in each tour for officer, wife and up to three children under 18 years of age. Generous leave. Education allowances.

Apply, stating name in full and giving brief particulars of qualifications and experience, to Director of Recruitment, Colonial Office, S.W.1, quoting BCD.197/200/028/C1.

JUNIOR TECHNICIAN FOR BIOCHEMICAL work required at once at Twyford Laboratories Ltd., Twyford Abbey Road, London, N.W.10. Training given in general laboratory and workshop practice, leading to assisting in research projects. Best of conditions and prospects. G.C.E. advanced level in two science subjects or equivalent required.—Apply to Secretary at above address.
